A Compatibility 47
  A.1 C++ extensions for Concepts with Reflection and ISO C++ 2014 ....................................................... 47
1 General

1.1 Scope

This document describes extensions to the C++ Programming Language (Clause 1.2) that enable operations on source code. These extensions include new syntactic forms and modifications to existing language semantics, as well as changes and additions to the existing library facilities.

The International Standard, ISO/IEC 14882, together with the C++ Extensions for Concepts, ISO/IEC TS 19217:2015 provide important context and specification for this document. This document is written as a set of changes against the specification of ISO/IEC 14882, as modified by C++ Extensions for Concepts, ISO/IEC TS 19217:2015. Instructions to modify or add paragraphs are written as explicit instructions. Modifications made directly to existing text from the International Standard use underlining to represent added text and strikethrough to represent deleted text.
1.2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

(1.1) — ISO/IEC 14882:2014, Programming Languages — C++

(1.2) — ISO/IEC TS 19217:2015, Programming Languages — C++ Extensions for Concepts

ISO/IEC 14882 is hereafter called the C++ Standard. ISO/IEC TS 19217:2015 is hereafter called the Concepts-TS.

The numbering of clauses, subclauses, and paragraphs in this document reflects the numbering in the C++ Standard as modified by the Concepts-TS. References to clauses and subclauses not appearing in this document refer to the original unmodified text in the C++ Standard.
1.3 Terms and definitions

No terms and definitions are listed in this document. ISO and IEC maintain terminological databases for use in standardization at the following addresses:

(1.1) — IEC Electropedia: available at http://www.electropedia.org/
(1.2) — ISO Online browsing platform: available at http://www.iso.org/obp
1.4 Implementation compliance

Conformance requirements for this specification are those defined in subclause 1.4 in the C++ Standard. Similarly, all references to the C++ Standard in the resulting document shall be taken as referring to the resulting document itself. [Note: Conformance is defined in terms of the behavior of programs. — end note]

1.5 Namespaces and headers

Whenever a name \( x \) declared in subclause 18.11 at namespace scope is mentioned, the name \( x \) is assumed to be fully qualified as ::std::experimental::reflect::v1::x, unless otherwise specified. The header described in this specification (see Table 1) shall import the contents of ::std::experimental::reflect::v1 into ::std::experimental::reflect as if by:

```cpp
namespace std::experimental::reflect {
  inline namespace v1 {};
}
```

Whenever a name \( x \) declared in the standard library at namespace scope is mentioned, the name \( x \) is assumed to be fully qualified as ::std::x, unless otherwise specified.

Table 1 — Reflection library headers

<table>
<thead>
<tr>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;experimental/reflect&gt;</td>
</tr>
</tbody>
</table>

1.6 Feature-testing recommendations

An implementation that provides support for this Technical Specification shall define each feature test macro defined in Table 2 if no associated headers are indicated for that macro, and if associated headers are indicated for a macro, that macro is defined after inclusion of one of the corresponding headers specified in the table.

Table 2 — Feature-test macros

<table>
<thead>
<tr>
<th>Macro name</th>
<th>Value</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td>__cpp_reflection</td>
<td>201902</td>
<td>none</td>
</tr>
<tr>
<td>__cpp_lib_reflection</td>
<td>201902</td>
<td>&lt;experimental/reflect&gt;</td>
</tr>
</tbody>
</table>

1.7 Acknowledgements

This work is the result of a collaboration of researchers in industry and academia. We wish to thank the original authors of this TS, Matúš Chochlík, Axel Naumann, and David Sankel. We also wish to thank people who made valuable contributions within and outside these groups, including Ricardo Fabiano de Andrade, Roland Bock, Chandler Carruth, Jackie Kay, A. Joël Lamotte, Jens Maurer, and many others not named here who contributed to the discussion.
2 Lexical conventions

2.12 Keywords

1 In C++ [lex.key], add the keyword \texttt{reflexpr} to the list of keywords in Table 4.
3 Basic concepts [basic]

1 In C++ [basic], add the following last paragraph:

   An alias is a name introduced by a typedef declaration, an alias-declaration, or a using-declaration.

3.2 One definition rule [basic.def.odr]

1 In C++ [basic.def.odr], insert a new paragraph after the existing paragraph 3:

   A function or variable of static storage duration reflected by T (7.1.6.5) is odr-used by the specialization std::experimental::reflect::get_pointer<T> (18.11.4.9, 18.11.4.17), as if by taking the address of an id-expression nominating the function or variable.

2 In C++ [basic.def.odr], apply the following changes to the second bullet within paragraph 6:

   and the object has the same value in all definitions of D, or a type implementing std::experimental::reflect::Object (18.11.3.1), as long as all operations (18.11.4) on this type yield the same constant expression results; and

3.9 Types [basic.types]

3.9.1 Fundamental types [basic.fundamental]

1 In C++ [basic.fundamental], apply the following change to paragraph 9:

   An expression of type void shall be used only as an expression statement (6.2), as an operand of a comma expression (5.18), as a second or third operand of ?: (5.16), as the operand of typeid, noexcept, reflexpr, or decltype, as the expression in a return statement (6.6.3) for a function with the return type void, or as the operand of an explicit conversion to type cv void.
4 Standard conversions

No changes are made to Clause 4 of the C++ Standard.
5 Expressions

5.1 Primary expressions

5.1.2 Lambda expressions

1 In C++ [expr.prim.lambda], apply the following change to the second bullet in paragraph 12:

— names the entity in a potentially-evaluated expression (3.2) where the enclosing full-expression
  depends on a generic lambda parameter declared within the reaching scope of the lambda-
  expression;

where, for the process of this determination, reflexpr operands are not considered to be unevaluated
operands.

2 Also apply the following change to paragraph 18:

Every id-expression within the compound-statement of a lambda-expression that is an odr-
use (3.2) of an entity captured by copy as well as every use of an entity captured by copy in a
reflexpr-operand, is transformed into an access to the corresponding unnamed data member of
the closure type.

5.2 Postfix expressions

1 In C++ [expr.post], apply the following change:

postfix-expression:
  primary-expression
  postfix-expression [ expression ]
  postfix-expression [ braced-init-list ]
  postfix-expression ( expression-list opt )
  function-call-expression
  simple-type-specifier ( expression-list opt )
  typename-specifier ( expression-list opt )
  simple-type-specifier-braced-init-list
  typename-specifier-braced-init-list
  functional-type-conv-expression
  postfix-expression . template_opt id-expression
  postfix-expression -> template_opt id-expression
  postfix-expression . pseudo-destructor-name
  postfix-expression -> pseudo-destructor-name
  postfix-expression ++
  postfix-expression --
  dynamic_cast < type-id > ( expression )
  static_cast < type-id > ( expression )
  reinterpret_cast < type-id > ( expression )
  const_cast < type-id > ( expression )
  typeid ( expression )
  typeid ( type-id )

function-call-expression:
  postfix-expression ( expression-list_opt )

functional-type-conv-expression:
  simple-type-specifier ( expression-list_opt )
  typename-specifier ( expression-list_opt )
  simple-type-specifier-braced-init-list
  typename-specifier-braced-init-list
expression-list:
  initializer-list
6 Statements

No changes are made to Clause 6 of the C++ Standard.
7  Declarations

7.1  Specifiers

7.1.6  Type specifiers

7.1.6.2  Simple type specifiers

In C++ [dcl.type.simple], apply the following change:

The simple type specifiers are

```
simple-type-specifier:
    nested-name-specifier_opt type-name
    nested-name-specifier template simple-template-id
    char
    char16_t
    char32_t
    wchar_t
    bool
    short
    int
    long
    signed
    unsigned
    float
    double
    void
    auto
    decltype-specifier
    reflexpr-specifier

type-name:
    class-name
    enum-name
    typedef-name
    simple-template-id

decltype-specifier:
    decltype ( expression )
    decltype ( auto )

reflexpr-specifier:
    reflexpr ( reflexpr-operand )

reflexpr-operand:
    ::
    type-id
    nested-name-specifier_opt namespace-name
    id-expression
    ( expression )
    function-call-expression
    functional-type-conv-expression
```

...
The other *simple-type-specifiers* specify either a previously-declared type, a type determined from an expression, a *reflection meta-object type* (7.1.6.5), or one of the fundamental types (3.9.1).

2 Append the following row to Table 10:

| `reflexpr ( reflexpr-operand )` | the type as defined below |

3 At the end of 7.1.6.2, insert the following paragraph:

For a `reflexpr-operand` `x`, the type denoted by `reflexpr(x)` is a type that satisfies the constraints laid out in 7.1.6.5.

### 7.1.6.5 Reflection type specifiers

Insert the following subclause:

1 The `reflexpr-specifier` yields a type `T` that allows inspection of some properties of its operand through type traits or type transformations on `T` (18.11.4). The operand to the `reflexpr-specifier` shall be a type, namespace, enumerator, variable, data member, function parameter, captured entity, parenthesized expression, `function-call-expression` or `functional-type-conv-expression`. Any such `T` satisfies the requirements of `reflect::Object` (18.11.3) and other `reflect` concepts, depending on the operand. A type satisfying the requirements of `reflect::Object` is called a *meta-object type*. A meta-object type is an unnamed, incomplete namespace-scope class type (Clause 9).

2 An entity or alias `B` is *reflection-related* to an entity or alias `A` if
   1. `A` and `B` are the same entity or alias,
   2. `A` is a variable or enumerator and `B` is the type of `A`,
   3. `A` is an enumeration and `B` is the underlying type of `A`,
   4. `A` is a class and `B` is a member or base class of `A`,
   5. `A` is a non-template alias that designates the entity `B`,
   6. `A` is not the global namespace and `B` is an enclosing class or namespace of `A`,
   7. `A` is the parenthesized expression `(B)`.
   8. `A` is a lambda capture of the closure type `B`,
   9. `A` is the closure type of the lambda capture `B`,
   10. `B` is the type specified by the `functional-type-conv-expression` `A`,
   11. `B` is the function selected by overload resolution for a `function-call-expression` `A`,
   12. `B` is the return type, a parameter type, or function type of the function `A`, or
   13. `B` is reflection-related to an entity or alias `X` and `X` is reflection-related to `A`.

3 [Note: This relationship is reflexive and transitive, but not symmetric. — end note]

4 [Example:

   ```
   struct X;
   struct B {
   using X = ::X;
   typedef X Y;
   };
   struct D : B {
   using B::Y;
   };
   ```

   The alias `D::Y` is reflection-related to `::X`, but not to `B::Y` or `B::X`. — end example]

5 Zero or more successive applications of type transformations that yield meta-object types (18.11.4) to the type denoted by a `reflexpr-specifier` enable inspection of entities and aliases that are reflection-related to the operand; such a meta-object type is said to *reflect* the respective reflection-related entity or alias.

6 [Example:

   ```
   struct X;
   struct B {
   using X = ::X;
   typedef X Y;
   };
   struct D : B {
   using B::Y;
   };
   ```

   The alias `D::Y` is reflection-related to `::X`, but not to `B::Y` or `B::X`. — end example]
template <typename T> std::string get_type_name() {
    namespace reflect = std::experimental::reflect;
    // T_t is an Alias reflecting T:
    using T_t = reflexpr(T);
    // aliased_T_t is a Type reflecting the type for which T is a synonym:
    using aliased_T_t = reflect::get_aliased_t<T_t>
    return reflect::get_name_v<aliased_T_t>;
}

std::cout << get_type_name<std::string>(); // outputs basic_string

— end example

It is unspecified whether repeatedly applying reflexpr to the same operand yields the same type or a different type. [Note: If a meta-object type reflects an incomplete class type, certain type transformations (18.11.4) cannot be applied. — end note]

[Example:

    class X;
    using X1_m = reflexpr(X);
    class X {};
    using X2_m = reflexpr(X);
    using X_bases_1 = std::experimental::reflect::get_base_classes_t<X1_m>; // OK:
                        // X1_m reflects complete class X
    using X_bases_2 = std::experimental::reflect::get_base_classes_t<X2_m>; // OK
    std::experimental::reflect::get_reflected_type_t<X1_m> x; // OK: type X is complete

    — end example]

For the operand ::, the type specified by the reflexpr-specifier satisfies reflect::GlobalScope. Otherwise, the type specified by the reflexpr-specifier satisfies concepts depending on the result of name lookup, as shown in Table 11. Any other reflexpr-operand renders the program ill-formed.

If the reflexpr-operand of the form id-expression is a constant expression, the type specified by the reflexpr-specifier also satisfies reflect::Constant.

If the reflexpr-operand designates a name whose declaration is enclosed in a block scope (3.3.3) and the named entity is neither captured nor a function parameter, the program is ill-formed. If the reflexpr-operand designates a class member, the type represented by the reflexpr-specifier also satisfies reflect::RecordMember. If the reflexpr-operand designates an expression, it is an unevaluated operand (Clause 5). If the reflexpr-operand designates both an alias and a class name, the type represented by the reflexpr-specifier reflects the alias and satisfies reflect::Alias.
Table 11 — `reflect` concept (18.11.3) that the type specified by a `reflexpr-specifier` satisfies, for a given `reflexpr-operand`.

</tbody>
</table>

\(^a\) For a `reflexpr-operand` that is a parenthesized expression (E). E shall be a `function-call-expression`, `functional-type-conv-expression`, or an expression (E') that satisfies the requirements for being a `reflexpr-operand`.

\(^b\) If the postfix-expression of the `function-call-expression` is of class type, the function call shall not resolve to a surrogate call function (13.3.1.1.2). Otherwise, the postfix-expression shall name a function that is the unique result of overload resolution.

\(^c\) The usual disambiguation between function-style cast and a `type-id` (8.2) applies. | Example: The default constructor of class X can be reflected on as `reflexpr((X()))` while `reflexpr(X())` reflects the type of a function returning X. — end example |
8 Declarators [dcl.decl]

8.1 Type names [dcl.name]

1 In C++ [dcl.name], apply the following changes:

To specify type conversions explicitly, and as an argument of sizeof, alignof, new, or typeid, or reflexpr, the name of a type shall be specified.
9 Classes

No changes are made to Clause 9 of the C++ Standard.
10 Derived classes

No changes are made to Clause 10 of the C++ Standard.
11 Member access control [class.access]

No changes are made to Clause 11 of the C++ Standard.
12 Special member functions [special]

No changes are made to Clause 12 of the C++ Standard.
13 Overloading

No changes are made to Clause 13 of the C++ Standard.
14 Templates

14.6 Name resolution

14.6.2 Dependent names

14.6.2.1 Dependent types

1 In C++ [temp.dep.type], apply the following changes to paragraph 8:

A type is dependent if it is

[...]

— denoted by `decltype(expression)`, where `expression` is type-dependent (14.6.2.2), or

— denoted by `reflexpr(operand)`, where `operand` is a type-dependent expression or a (possibly parenthesized) `functional-type-conv-expression` with at least one type-dependent immediate subexpression, or

— denoted by `reflexpr(operand)`, where `operand` designates a dependent type or a member of an unknown specialization or a value-dependent constant expression.
15 Exception handling

No changes are made to Clause 15 of the C++ Standard.
16 Preprocessing directives

No changes are made to Clause 16 of the C++ Standard.
17 Library introduction

17.6 Library-wide requirements

17.6.1 Library contents and organization

17.6.1.2 Headers

1 Add <experimental/reflect> to Table 14 – C++ library headers.

17.6.1.3 Freestanding implementations

Modify Table 16 as follows.

Table 16 — C++ headers for freestanding implementations

<table>

18  Language support library
[language.support]

1 Add a new subclause 18.11 titled 'Static reflection' as follows:

18.11 Static reflection  [reflect]
18.11.1 In general  [reflect.general]

1 As laid out in 7.1.6.5, compile-time constant metadata, describing various aspects of a program (static reflection data), can be accessed through meta-object types. The actual metadata is obtained by instantiating templates constituting the interface of the meta-object types. These templates are collectively referred to as meta-object operations.

2 Meta-object types satisfy different concepts (18.11.3) depending on the type they reflect (7.1.6.5). These concepts can also be used for meta-object type classification. They form a generalization-specialization hierarchy, with reflect::Object being the common generalization for all meta-object types. Unary operations and type transformations used to query static reflection data associated with these concepts are described in 18.11.4.

18.11.2 Header <experimental/reflect> synopsis  [reflect.synopsis]

namespace std {

18.11.3 Concepts for meta-object types

The operations on meta-object types defined here require meta-object types to satisfy certain concepts (7.1.7). These concepts are also used to specify the result type for TransformationTrait type transformations that yield meta-object types. [Note: Unlike std::is_enum, std::experimental::reflect::is_enum operates on meta-object types. —end note]

18.11.3.1 Concept Object

template <class T> concept bool Object = see below;

Object<T> is true if and only if T is a meta-object type, as generated by the reflexpr operator or any of the meta-object operations that in turn generate meta-object types.

18.11.3.2 Concept ObjectSequence

template <class T> concept bool ObjectSequence = Object<T> && see below;

ObjectSequence<T> is true if and only if T is a sequence of Objects, generated by a meta-object operation.
18.11.3.3 Concept TemplateParameterScope

```
template <class T> concept bool TemplateParameterScope = Scope<T> && see below;
```

TemplateParameterScope<T> is true if and only if T is a Scope reflecting the scope of a template type-parameter, generated by a metaobject operation. [Note: It represents the template parameter scope (3.3.9), providing a scope to the Alias reflecting a template type-parameter. —end note]

18.11.3.4 Concept Named

```
template <class T> concept bool Named = Object<T> && see below;
```

Named<T> is true if and only if T has an associated (possibly empty) name.

18.11.3.5 Concept Alias

```
template <class T> concept bool Alias = Named<T> && ScopeMember<T> && see below;
```

Alias<T> is true if and only if T reflects a typedef declaration, an alias-declaration, a namespace-alias, a template type-parameter, a decltype-specifier, or a declaration introduced by a using-declaration. [Note: The Scope of an Alias is the scope that the alias was injected into. For an Alias reflecting a template type-parameter, that scope is its TemplateParameterScope. —end note] [Example:

```cpp
namespace N {
    struct A;
}
namespace M {
    using X = N::A;
}
struct B {
    int i;
};
struct C {
    using B::i;
};
using M_X_t = reflexpr(M::X);
using M_X_scope_t = get_scope_t<M_X_t>;
using C_i_t = reflexpr(C::i);
using C_i_scope_t = get_scope_t<C_i_t>;
```

The scope reflected by M_X_scope_t is M, not N; the scope reflected by C_i_scope_t is C, not B. —end example]

Type transformations (18.11.4) never yield an Alias; instead, they yield the aliased entity.

18.11.3.6 Concept RecordMember

```
template <class T> concept bool RecordMember = ScopeMember<T> && see below;
```

RecordMember<T> is true if and only if T reflects a member-declaration.

18.11.3.7 Concept Enumerator

```
template <class T> concept bool Enumerator = Constant<T> && see below;
```

Enumerator<T> is true if and only if T reflects an enumerator. [Note: The Scope of an Enumerator is its type also for enumerations that are unscoped enumeration types. —end note]

18.11.3.8 Concept Variable

```
template <class T> concept bool Variable = Typed<T> && ScopeMember<T> && see below;
```

Variable<T> is true if and only if T reflects a variable or data member.
18.11.3.9 Concept ScopeMember

\[
\text{template<typename T> concept bool ScopeMember = Named<T> \&\& \text{see below;}}
\]

\[\text{ScopeMember<T> is true if and only if T satisfies RecordMember, Enumerator, or Variable, or if T reflects a namespace that is not the global namespace. [Note: The scope of members of an unnamed union is the unnamed union; the scope of enumerators is their type. — end note]}\]

18.11.3.10 Concept Typed

\[
\text{template<typename T> concept bool Typed = Object<T> \&\& \text{see below;}}
\]

\[\text{Typed<T> is true if and only if T reflects an entity with a type.}\]

18.11.3.11 Concept Namespace

\[
\text{template<typename T> concept bool Namespace = Named<T> \&\& \text{Scope<T} \&\& \text{see below;}}
\]

\[\text{Namespace<T> is true if and only if T reflects a namespace (including the global namespace). [Note: Any such T that does not reflect the global namespace also satisfies ScopeMember. — end note]}\]

18.11.3.12 Concept GlobalScope

\[
\text{template<typename T> concept bool GlobalScope = Namespace<T> \&\& \text{see below;}}
\]

\[\text{GlobalScope<T> is true if and only if T reflects the global namespace. [Note: Any such T does not satisfy ScopeMember. — end note]}\]

18.11.3.13 Concept Class

\[
\text{template<typename T> concept bool Class = Record<T> \&\& \text{see below;}}
\]

\[\text{Class<T> is true if and only if T reflects a non-union class type.}\]

18.11.3.14 Concept Enum

\[
\text{template<typename T> concept bool Enum = Type<T> \&\& \text{Scope<T} \&\& \text{ScopeMember<T} \&\& \text{see below;}}
\]

\[\text{Enum<T> is true if and only if T reflects an enumeration type.}\]

18.11.3.15 Concept Record

\[
\text{template<typename T> concept bool Record = Type<T> \&\& \text{Scope<T} \&\& \text{ScopeMember<T} \&\& \text{see below;}}
\]

\[\text{Record<T> is true if and only if T reflects a class type.}\]

18.11.3.16 Concept Scope

\[
\text{template<typename T> concept bool Scope = Object<T> \&\& \text{see below;}}
\]

\[\text{Scope<T> is true if and only if T reflects a namespace (including the global namespace), class, enumeration, function, closure type, or is a TemplateParameterScope. [Note: Any such T that does not reflect the global namespace also satisfies ScopeMember. — end note]}\]

18.11.3.17 Concept Type

\[
\text{template<typename T> concept bool Type = Named<T> \&\& \text{see below;}}
\]

\[\text{Type<T> is true if and only if T reflects a type. [Note: Some types T also satisfy ScopeMember; others, for instance those reflecting cv-qualified types or fundamental types, do not. — end note]}\]
18.11.3.18 Concept Constant

```cpp
template <class T> concept bool Constant = Typed<T> && ScopeMember<T> && see below;
```

Constant<T> is true if and only if T reflects an enumerator or a constexpr variable.

18.11.3.19 Concept Base

```cpp
template <class T> concept bool Base = Object<T> && see below;
```

Base<T> is true if and only if T reflects a direct base class, as returned by the template get_base_classes.

18.11.3.20 Concept FunctionParameter

```cpp
template <class T> concept bool FunctionParameter = Typed<T> && ScopeMember<T> && see below;
```

FunctionParameter<T> is true if and only if T reflects a function parameter. [Note: The Scope of a FunctionParameter is the Callable to which this parameter appertains. —end note] [Note: A FunctionParameter does not satisfy Variable, and thus does not offer an interface for getting the pointer to a parameter. —end note]

18.11.3.21 Concept Callable

```cpp
template <class T> concept bool Callable = Scope<T> && ScopeMember<T> && see below;
```

Callable<T> is true if and only if T reflects a function, including constructors and destructors.

18.11.3.22 Concept Expression

```cpp
template <class T> concept bool Expression = Object<T> && see below;
```

Expression<T> is true if and only if T reflects an expression (Clause 5).

18.11.3.23 Concept ParenthesizedExpression

```cpp
template <class T> concept bool ParenthesizedExpression = Expression<T> && see below;
```

ParenthesizedExpression<T> is true if and only if T reflects a parenthesized expression (5.1.1).

18.11.3.24 Concept FunctionCallExpression

```cpp
template <class T> concept bool FunctionCallExpression = Expression<T> && see below;
```

FunctionCallExpression<T> is true if and only if T reflects a function-call-expression (5.2.2).

18.11.3.25 Concept FunctionalTypeConversion

```cpp
template <class T> concept bool FunctionalTypeConversion = Expression<T> && see below;
```

FunctionalTypeConversion<T> is true if and only if T reflects a functional-type-conv-expression (5.2.3).

18.11.3.26 Concept Function

```cpp
template <class T> concept bool Function = Typed<T> && Callable<T> && see below;
```

Function<T> is true if and only if T reflects a function, excluding constructors and destructors.

18.11.3.27 Concept MemberFunction

```cpp
template <class T> concept bool MemberFunction = RecordMember<T> && Function<T> && see below;
```

MemberFunction<T> is true if and only if T reflects a member function, excluding constructors and destructors.
18.11.3.28 Concept SpecialMemberFunction

```
template <class T> concept bool SpecialMemberFunction = RecordMember<T> && see below;
```

1 SpecialMemberFunction<T> is true if and only if T reflects a special member function (Clause 12).

18.11.3.29 Concept Constructor

```
template <class T> concept bool Constructor = Callable<T> && RecordMember<T> && see below;
```

1 Constructor<T> is true if and only if T reflects a constructor. [Note: Some types that satisfy Constructor also satisfy SpecialMemberFunction. — end note]

18.11.3.30 Concept Destructor

```
template <class T> concept bool Destructor = Callable<T> && SpecialMemberFunction<T> && see below;
```

1 Destructor<T> is true if and only if T reflects a destructor.

18.11.3.31 Concept Operator

```
template <class T> concept bool Operator = Function<T> && see below;
```

1 Operator<T> is true if and only if T reflects an operator function (13.5) or a conversion function (12.3.2). [Note: Some types that satisfy Operator also satisfy MemberFunction or SpecialMemberFunction. — end note]

18.11.3.32 Concept ConversionOperator

```
template <class T> concept bool ConversionOperator = MemberFunction<T> && Operator<T> && see below;
```

1 ConversionOperator<T> is true if and only if T reflects a conversion function (12.3.2).

18.11.3.33 Concept Lambda

```
template <class T> concept bool Lambda = Type<T> && Scope<T> && see below;
```

1 Lambda<T> is true if and only if T reflects a closure type (excluding generic lambdas).

18.11.3.34 Concept LambdaCapture

```
template <class T> concept bool LambdaCapture = Variable<T> && see below;
```

1 LambdaCapture<T> is true if and only if T reflects a lambda capture as introduced by the capture list or by capture defaults. [Note: The Scope of a LambdaCapture is its immediately enclosing Lambda. — end note]

18.11.4 Meta-object operations

A meta-object operation extracts information from meta-object types. It is a class template taking one or more arguments, at least one of which models the Object concept. The result of a meta-object operation can be either a constant expression (5.19) or a type.

Some operations specify result types with a nested type called type that satisfies one of the concepts in reflect. These nested types will possibly satisfy other concepts, for instance more specific ones, or independent ones, as applicable for the entity reflected by the nested type.

[Example:
```
struct X {}
X x;
using x_t = get_type_t<reflexpr(x)>;
```]
While \texttt{get\_type\_t} is specified to be a Type, \texttt{x\_t} also satisfies Class. — end example] Alias entities are not returned by meta-object operations (18.11.3.5).

If subsequent specializations of operations on the same reflected entity could give different constant expression results (for instance for \texttt{get\_name\_v} because the parameter’s function is re-declared with a different parameter name between the two points of instantiation), the program is ill-formed, no diagnostic required. [Example:

```cpp
void func(int a);
auto x1 = get\_name\_v<get\_element\_t<0, get\_parameters\_t<reflexpr(func(42))>>;  // ill-formed,
void func(int b);
auto x2 = get\_name\_v<get\_element\_t<0, get\_parameters\_t<reflexpr(func(42))>>;  // no diagnostic required

— end example]
```

18.11.4.1 Object operations [reflect.ops.object]

```cpp
template <Object T1, Object T2> struct reflects\_same;
```

All specializations of \texttt{reflects\_same<T1, T2>} shall meet the BinaryTypeTrait requirements (20.10.1), with a base characteristic of \texttt{true\_type} if

\begin{itemize}
\item \texttt{T1} and \texttt{T2} reflect the same alias, or
\item neither \texttt{T1} nor \texttt{T2} reflect an alias and \texttt{T1} and \texttt{T2} reflect the same aspect;
\end{itemize}

otherwise, with a base characteristic of \texttt{false\_type}.

[Example: With

```cpp
class A;
using a0 = reflexpr(A);
using a1 = reflexpr(A);
class A {};
using a2 = reflexpr(A);
constexpr bool b1 = is\_same\_v<a0, a1>;  // unspecified value
constexpr bool b2 = reflects\_same\_v<a0, a1>;  // true
constexpr bool b3 = reflects\_same\_v<a0, a2>;  // true
```

```cpp
struct C {};
using C1 = C;
using C2 = C;
constexpr bool b4 = reflects\_same\_v<reflexpr(C1), reflexpr(C2)>;  // false

— end example]
```

```cpp
template <Object T> struct get\_source\_line;
```

```cpp
template <Object T> struct get\_source\_column;
```

All specializations of above templates shall meet the UnaryTypeTrait requirements (20.10.1) with a base characteristic of \texttt{integral\_constant<uint\_least32\_t>} and a value of the presumed line number (16.8) (for \texttt{get\_source\_line<T>}) and an implementation-defined value representing some offset from the start of the line (for \texttt{get\_source\_column<T>}) of a declaration of the entity or typedef described by \texttt{T}.

```cpp
template <Object T> struct get\_source\_file\_name;
```

All specializations of \texttt{get\_source\_file\_name<T>} shall meet the UnaryTypeTrait requirements (20.10.1) with a static data member named value of type \texttt{const char (&)[N]}, referencing a static, constant expression character array (NTBS) of length \texttt{N}, as if declared as static

```cpp
constexpr char STR[N] = ...;
```

The value of the NTBS is the presumed name of the source file (16.8) of a declaration of the entity or typedef described by \texttt{T}. 

§ 18.11.4.1 © ISO/IEC 2020 – All rights reserved 37
18.11.4.2 ObjectSequence operations

```
template <ObjectSequence T> struct get_size;
```

All specializations of `get_size<T>` shall meet the `UnaryTypeTrait` requirements (20.10.1) with a base characteristic of `integral_constant<size_t, N>` where `N` is the number of elements in the object sequence.

```
template <size_t I, ObjectSequence T> struct get_element;
```

All specializations of `get_element<I, T>` shall meet the `TransformationTrait` requirements (20.10.1). The nested type named `type` corresponds to the `I`th element `Object` in `T`, where the indexing is zero-based.

```
template <template <class...> class Tpl, ObjectSequence T> struct unpack_sequence;
```

All specializations of `unpack_sequence<Tpl, T>` shall meet the `TransformationTrait` requirements (20.10.1). The nested type named `type` designates the template `Tpl` specialized with the element `Object` in `T`.

18.11.4.3 Named operations

```
template <Named T> struct is_unnamed;
template <Named T> struct get_name;
template <Named T> struct get_display_name;
```

All specializations of `is_unnamed<T>` shall meet the `UnaryTypeTrait` requirements (20.10.1) with a base characteristic as specified below.

All specializations of `get_name<T>` and `get_display_name<T>` shall meet the `UnaryTypeTrait` requirements (20.10.1) with a static data member named value of type `const char (&)[N]`, referencing a static, constant expression character array (NTMBS) of length `N`, as if declared as `static constexpr char STR[N] = ...;`.

The value of `get_display_name_v<T>` is the empty string if `T` reflects an unnamed entity; otherwise the value is implementation defined.

The value of `get_name_v<T>` refers to a string literal whose s-char-sequence is obtained by the first matching case in the following list:

- for `T` reflecting an alias, the unqualified name of the aliasing declaration;
- for `T` reflecting an unnamed entity, the empty string;
- for `T` reflecting a specialization of a class, function (except for conversion functions, constructors, operator functions, or literal operators), or variable template, its template-name:
  - a `type-parameter`, the identifier introduced by the `type-parameter`;
  - a class type, its `class-name`;
  - an enumeration type, its `enum-name`;
  - a fundamental type other than `std::nullptr_t`, the name stated in the "Type" column of Table 10 in 7.1.6.2;
- for `T` reflecting
  - a namespace, its `namespace-name`;
  - a variable, enumerator, data member, or function (except for conversion functions, constructors, operator functions, or literal operators), its unqualified name;
  - a function parameter, its name;
  - a constructor, the `injected-class-name` of its class;
  - a destructor, the `injected-class-name` of its class, prefixed by the character ~;
  - an operator function, the `operator-function-id`;
  - a literal operator, the s-char-sequence "\" followed by the literal suffix identifier of the operator's `literal-operator-id`;
  - a conversion function, the same characters as `get_name_v<R>`, with `R` reflecting the type represented by the `conversion-type-id`.
- In all other cases, the string's value is the empty string.
[Note: With]

namespace n { template <class T> class A; }
using a_m = reflexpr(n::A<int>);

the value of get_name_v<a_m> is "A" while the value of get_display_name_v<a_m> might be "n::A<int>". — end note]

The base characteristic of is_unnamed<T> is true_type if the value of get_name_v<T> is the empty string, otherwise it is false_type.

Subsequent specializations of get_name<T> on the same reflected function parameter can render the program ill-formed, no diagnostic required (18.11.4).

18.11.4.4 Alias operations

```cpp
template <Alias T> struct get_aliased;
```

All specializations of get_aliased<T> shall meet the TransformationTrait requirements (20.10.1).

The nested type named type is the Named meta-object type reflecting

1. the redefined name, if T reflects an alias;
2. the template specialization’s template argument type, if T reflects a template type-parameter;
3. the original declaration introduced by a using declaration;
4. the aliased namespace of a namespace-alias;
5. the type denoted by the decltype-specifier.

The nested type named type is not an Alias; instead, it is reflecting the underlying non-Alias entity.

```cpp
using i0 = int; using i1 = i0;
get_aliased_t<reflexpr(i1)> reflects int. — end example]
```

18.11.4.5 Type operations

```cpp
template <Typed T> struct get_type;
```

All specializations of get_type<T> shall meet the TransformationTrait requirements (20.10.1).

The nested type named type is the Type reflecting the type of the entity reflected by T.

```cpp
int v; using v_m = reflexpr(v);
get_type_t<v_m> reflects int. — end example]
```

If the entity reflected by T is a static data member that is declared to have a type array of unknown bound in the class definition, possible specifications of the array bound will only be accessible when the reflexpr-operand is the data member.

```cpp
[Note: For

```cpp
struct C {
    static int arr[][17];
};
int C::arr[42][17];
using C1 = get_type_t<get_element_t<0, get_data_members_t<reflexpr(C)>>>;
using C2 = get_type_t<reflexpr(C::arr)>;
```

C1 reflects int[][17] while C2 reflects int[42][17]. — end note]
```

```cpp
template <Type T> struct get_reflected_type;
```

All specializations of get_reflected_type<T> shall meet the TransformationTrait requirements (20.10.1).

The nested type named type is the type reflected by T.

```cpp
[Example: For

```cpp
struct C {
    static int arr[][17];
};
int C::arr[42][17];
using C1 = get_type_t<get_element_t<0, get_data_members_t<reflexpr(C)>>>;
using C2 = get_type_t<reflexpr(C::arr)>;
```

C1 reflects int[][17] while C2 reflects int[42][17]. — end note]
```
using int_m = reflexpr(int);
get_reflected_type_t<int_m> x; // x is of type int

— end example]
template <Type T> struct is_enum;
template <Type T> struct is_union;

7 All specializations of is_enum<T> and is_union<T> shall meet the UnaryTypeTrait requirements (20.10.1). If T reflects an enumeration type (a union), the base characteristic of is_enum<T> (is_union<T>) is true_type, otherwise it is false_type.

template <Class T> struct uses_class_key;
template <Class T> struct uses_struct_key;

8 All specializations of uses_class_key<T> and uses_struct_key<T> shall meet the UnaryTypeTrait requirements (20.10.1). If T reflects a class for which all declarations use class-key class (for uses_class_key<T>) or struct (for uses_struct_key<T>), the base characteristic of the respective template specialization is true_type. If T reflects a class for which no declaration uses class-key class (for uses_class_key<T>) or struct (for uses_struct_key<T>), the base characteristic of the respective template specialization is false_type. Otherwise, it is unspecified whether the base characteristic is true_type or false_type.

18.11.4.6 Member operations

A specialization of any of these templates with a meta-object type that is reflecting an incomplete type renders the program ill-formed. Such errors are not in the immediate context (14.8.2).

template <ScopeMember T> struct get_scope;

2 All specializations of get_scope<T> shall meet the TransformationTrait requirements (20.10.1). The nested type named type is the Scope reflecting a scope S. With ST being the scope of the declaration of the entity, alias or value reflected by T, S is found as the innermost scope enclosing ST that is either a namespace scope (including global scope), class scope, enumeration scope, function scope, or immediately enclosing closure type (for lambda captures). For members of an unnamed union, this innermost scope is the unnamed union. For enumerators of unscoped enumeration types, this innermost scope is their enumeration type. For a template type-parameter, this innermost scope is the TemplateParameterScope representing the template parameter scope in which it has been declared.

template <RecordMember T> struct is_public<T>;
template <RecordMember T> struct is_protected<T>;
template <RecordMember T> struct is_private<T>;

3 All specializations of these partial template specializations shall meet the UnaryTypeTrait requirements (20.10.1). If T reflects a public member (for is_public), protected member (for is_protected), or private member (for is_private), the base characteristic of the respective template specialization is true_type, otherwise it is false_type.

18.11.4.7 Record operations

A specialization of any of these templates with a meta-object type that is reflecting an incomplete type renders the program ill-formed. Such errors are not in the immediate context (14.8.2). Members introduced by using-declarations (7.3.3) are included in the sequences below where applicable; the Scope of these members remains that of the declaration of the referenced entity. [Note: These members are not Aliases, see 18.11.4. A member injected into a derived class may have different access. — end note]

template <Record T> struct get_public_data_members;
template <Record T> struct get_accessible_data_members;
template <Record T> struct get_data_members;
template <Record T> struct get_public_member_functions;
template <Record T> struct get_accessible_member_functions;
template <Record T> struct get_member_functions;
All specializations of these templates shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a meta-object type satisfying ObjectSequence, containing elements which satisfy RecordMember and reflect the following subset of non-template members that are either declared in the class reflected by T or that are introduced by a using-declaration in the class reflected by T:

- for get_data_members (get_member_functions), all data (function, including constructor and destructor) members.
- for get_public_data_members (get_public_member_functions), all public data (function, including constructor and destructor) members;
- for get_accessible_data_members (get_accessible_member_functions), all data (function, including constructor and destructor) members that are accessible from the context of the invocation of reflexpr which (directly or indirectly) generated T. [Example:

```
class X {
  int a;

  friend struct Y;
};

struct Y {
  using X_t = reflexpr(X);
};

using X_mem_t = get_accessible_data_members_t<Y::X_t>;
static_assert(get_size_v<X_mem_t> == 1, ""); // passes.
```

— end example]

The order of the elements in the ObjectSequence is the order of the declaration of the members in the class reflected by T.

Remarks: The program is ill-formed if T reflects a closure type.

All specializations of these templates shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a meta-object type satisfying ObjectSequence, containing elements which satisfy RecordMember and reflect the following subset of non-template function members that are either declared in the class reflected by T or that are introduced by a using-declaration in function members of the class reflected by T:

- for get_constructors, all constructors.
- for get_operators, all conversion functions (12.3.2) and operator functions (13.5).

The order of the elements in the ObjectSequence is the order of the declaration of the members in the class reflected by T.

Remarks: The program is ill-formed if T reflects a closure type.

All specializations of these templates shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a Destructor type that reflects the destructor declared in the class reflected by T.

Remarks: The program is ill-formed if T reflects a closure type.

All specializations of these templates shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a meta-object type satisfying ObjectSequence, containing elements which satisfy Type and reflect the following subset of non-template types that are either declared in the class reflected by T or that are introduced by a using declaration in the class reflected by T:
— for \texttt{get\_public\_member\_types}, all public nested class types, enum types, or member typedefs;

— for \texttt{get\_accessible\_member\_types}, all nested class types, enum types, or member typedefs that are accessible from the scope of the invocation of \texttt{reflexpr} which (directly or indirectly) generated \texttt{T};

— for \texttt{get\_member\_types}, all nested class types, enum types, or member typedefs.

The order of the elements in the \texttt{ObjectSequence} is the order of the first declaration of the types in the class reflected by \texttt{T}.

\textbf{Remarks:} The program is ill-formed if \texttt{T} reflects a closure type.

template <Class T> struct get_public_base_classes;
template <Class T> struct get_accessible_base_classes;
template <Class T> struct get_base_classes;

All specializations of these templates shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a meta-object type satisfying \texttt{ObjectSequence}, containing elements which satisfy \texttt{Base} and reflect the following subset of base classes of the class reflected by \texttt{T}:

— for \texttt{get\_public\_base\_classes}, all public direct base classes;

— for \texttt{get\_accessible\_base\_classes}, all direct base classes whose public members are accessible from the scope of the invocation of \texttt{reflexpr} which (directly or indirectly) generated \texttt{T};

— for \texttt{get\_base\_classes}, all direct base classes.

The order of the elements in the \texttt{ObjectSequence} is the order of the declaration of the base classes in the class reflected by \texttt{T}.

\textbf{Remarks:} The program is ill-formed if \texttt{T} reflects a closure type.

template <Class T> struct is_final<T>;

All specializations of \texttt{is\_final<T>} shall meet the UnaryTypeTrait requirements (20.10.1). If \texttt{T} reflects a class that is marked with the \texttt{class-virt-specifier} \texttt{final}, the base characteristic of the respective template specialization is \texttt{true\_type}, otherwise it is \texttt{false\_type}.

\subsection{Enum operations} \label{reflect.ops.enum}

template <Enum T> struct is_scoped_enum;

All specializations of \texttt{is\_scoped\_enum<T>} shall meet the UnaryTypeTrait requirements (20.10.1). If \texttt{T} reflects a scoped enumeration, the base characteristic of the respective template specialization is \texttt{true\_type}, otherwise it is \texttt{false\_type}.

template <Enum T> struct get_enumerators;

All specializations of \texttt{get\_enumerators<T>} shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a meta-object type satisfying \texttt{ObjectSequence}, containing elements which satisfy \texttt{Enumerator} and reflect the enumerators of the enumeration type reflected by \texttt{T}.

\textbf{Remarks:} A specialization of this template with a meta-object type that is reflecting an incomplete type renders the program ill-formed. Such errors are not in the immediate context (14.8.2).

template <Enum T> struct get_underlying_type;

All specializations of \texttt{get\_underlying\_type<T>} shall meet the TransformationTrait requirements (20.10.1). The nested type named type designates a meta-object type that reflects the underlying type (7.2) of the enumeration reflected by \texttt{T}.

\textbf{Remarks:} A specialization of this template with a meta-object type that is reflecting an incomplete type renders the program ill-formed. Such errors are not in the immediate context (14.8.2).
18.11.4.9 Value operations

```
template <Constant T> struct get_constant;
1  All specializations of get_constant<T> shall meet the UnaryTypeTrait requirements (20.10.1).
   The type and value of the static data member named value are those of the constant expression of the constant reflected by T.

template <Variable T> struct isconstexpr<T>;
2  All specializations of this partial template specialization shall meet the UnaryTypeTrait requirements (20.10.1). If T reflects a variable declared with the decl-specifier constexpr, the base characteristic of the respective template specialization is true_type, otherwise it is false_type.

template <Variable T> struct isstatic<T>;
3  All specializations of is_static<T> and is_thread_local<T> shall meet the UnaryTypeTrait requirements (20.10.1). If T reflects a variable with static (for is_static) or thread (for is_thread_local) storage duration, the base characteristic of the respective template specialization is true_type, otherwise it is false_type.

template <Variable T> struct get_pointer<T>;
4  If T reflects a reference with static storage duration, and the reference has no prior initialization or has not been initialized with an object of static storage duration, the specialization of get_pointer<T> has no member named type. Otherwise, the specialization of get_pointer<T> shall meet the UnaryTypeTrait requirements (20.10.1), with a static data member named value of type X and value x, where
   — for variables with static storage duration: X is add_pointer<Y>, where Y is the type of the variable reflected by T, and x is the address of that variable; otherwise,
   — X is the pointer-to-member type of the non-static data member reflected by T and x a pointer to that member.
```

18.11.4.10 Base operations

```
template <Base T> struct get_class;
1  All specializations of get_class<T> shall meet the TransformationTrait requirements (20.10.1).
   The nested type named type designates reflexpr(X), where X is the base class (without retaining possible Alias properties, see 18.11.3.5) reflected by T.

template <Base T> struct isvirtual<T>;
2  All specializations of these partial template specializations shall meet the UnaryTypeTrait requirements (20.10.1). If T reflects a direct base class with the virtual specifier (for is_virtual), with the public specifier or with an assumed (see 11.2) public specifier (for is_public), with the protected specifier (for is_protected), or with the private specifier or with an assumed private specifier (for is_private), then the base characteristic of the respective template specialization is true_type, otherwise it is false_type.

template <Base T> struct isprotected<T>;

template <Base T> struct isprivate<T>;
```

18.11.4.11 Namespace operations

```
template <Namespace T> struct isinline<T>;
1  All specializations of is_inline<T> shall meet the UnaryTypeTrait requirements (20.10.1).
   If T reflects an inline namespace, the base characteristic of the template specialization is true_type, otherwise it is false_type.
```
18.11.4.12 FunctionParameter operations

```
template <FunctionParameter T> struct has_default_argument;
```

1 All specializations of this template shall meet the UnaryTypeTrait requirements (20.10.1). If \( T \) reflects a parameter with a default argument, the base characteristic of \( \text{has_default_argument}<T> \) is \text{true_type}, otherwise it is \text{false_type}.

2 Remarks: Subsequent specializations of \( \text{has_default_argument}<T> \) on the same reflected function parameter can render the program ill-formed, no diagnostic required (18.11.4).

18.11.4.13 Callable operations

```
template <Callable T> struct get_parameters;
```

1 All specializations of this template shall meet the TransformationTrait requirements (20.10.1). The nested type named \text{type} designates a meta-object type satisfying \text{ObjectSequence}, containing elements which satisfy FunctionParameter and reflect the parameters of the function reflected by \( T \). If that function’s \text{parameter-declaration-clause} (8.3.5) terminates with an ellipsis, the \text{ObjectSequence} does not contain any additional elements reflecting that. The \text{is_vararg_v<Callable>} trait can be used to determine if the terminating ellipsis is in its parameter list.

```
template <Callable T> struct is_vararg;
template <Callable T> struct is_constexpr<T>;
template <Callable T> struct is_noexcept;
template <Callable T> struct is_inline<T>;
```

2 All specializations of these templates and partial template specializations shall meet the UnaryTypeTrait requirements (20.10.1). If their template parameter reflects an entity with an ellipsis terminating the \text{parameter-declaration-clause} (8.3.5) (for \text{is_vararg}), or an entity that is (where applicable implicitly or explicitly) declared as \text{constexpr} (for \text{is_constexpr}), as non-throwing (15.4) (for \text{is_noexcept}), as an inline function (7.1.2) (for \text{is_inline}), or as deleted (for \text{is_deleted}), the base characteristic of the respective template specialization is \text{true_type}, otherwise it is \text{false_type}.

3 Remarks: Subsequent specializations of \text{is_inline<T>} on the same reflected function can render the program ill-formed, no diagnostic required (18.11.4).

18.11.4.14 ParenthesizedExpression operations

```
template <ParenthesizedExpression T> struct get_subexpression;
```

1 All specializations of \text{get_subexpression<T>} shall meet the TransformationTrait requirements (20.10.1). The nested type named \text{type} is the \text{Expression} type reflecting the expression \( E \) of the parenthesized expression \((E)\) reflected by \( T \).

18.11.4.15 FunctionCallExpression operations

```
template <FunctionCallExpression T> struct get_callable;
```

1 All specializations of \text{get_callable<T>} shall meet the TransformationTrait requirements (20.10.1). The nested type named \text{type} is the \text{Callable} type reflecting the function invoked by the \text{function-call-expression} which is reflected by \( T \).

18.11.4.16 FunctionalTypeConversion operations

```
template <FunctionalTypeConversion T> struct get_constructor;
```

All specializations of \text{get_constructor<T>} shall meet the TransformationTrait requirements (20.10.1). For a \text{functional-type-conv-expression} reflected by \( T \), let \( S \) be the type specified by the type conversion (5.2.3). If a constructor is used for the initialization of \( S \), the type \text{get_constructor<T>::type} is the \text{Constructor} reflecting that constructor; otherwise, \text{get_constructor<T>} has no member named type. [Note: For instance fundamental types (3.9.1) do not have constructors. — end note]
18.11.4.17 Function operations [reflect.ops.fct]

```cpp
template <Function T> struct get_pointer<T>;
```

1

All specializations of `get_pointer<T>` shall meet the `UnaryTypeTrait` requirements (20.10.1), with a static data member named value of type `X` and value `x`, where

(1.1) — for non-static member functions, `X` is the pointer-to-member-function type of the member function reflected by `T` and `x` a pointer to the member function; otherwise,

(1.2) — `X` is `add_pointer<Y>`, where `Y` is the type of the function reflected by `T` and `x` is the address of that function.

18.11.4.18 MemberFunction operations [reflect.ops.memfct]

```cpp
template <MemberFunction T> struct is_static<T>;
template <MemberFunction T> struct is_const;
template <MemberFunction T> struct is_volatile;
template <MemberFunction T> struct has_lvalueref_qualifier;
template <MemberFunction T> struct has_rvalueref_qualifier;
template <MemberFunction T> struct is_virtual<T>;
template <MemberFunction T> struct is_pure_virtual<T>;
template <MemberFunction T> struct is_override;
template <MemberFunction T> struct is_final<T>;
```

1

All specializations of these templates and partial template specializations shall meet the `UnaryTypeTrait` requirements (20.10.1). If their template parameter reflects a member function that is static (for `is_static`), const (for `is_const`), volatile (for `is_volatile`), declared with a ref-qualifier & (for `has_lvalueref_qualifier`) or && (for `has_rvalueref_qualifier`), implicitly or explicitly virtual (for `is_virtual`), pure virtual (for `is_pure_virtual`), or overrides a member function of a base class (for `is_override`) or final (for `is_final`), the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

18.11.4.19 SpecialMemberFunction operations [reflect.ops.specialfct]

```cpp
template <SpecialMemberFunction T> struct is_implicitly_declared;
template <SpecialMemberFunction T> struct is_defaulted;
```

1

All specializations of these templates shall meet the `UnaryTypeTrait` requirements (20.10.1). If their template parameter reflects a special member function that is implicitly declared (for `is_implicitly_declared`) or that is defaulted in its first declaration (for `is_defaulted`), the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

18.11.4.20 Constructor operations [reflect.ops.ctor]

```cpp
template <Constructor T> struct is_explicit<T>;
```

1

All specializations of this partial template specialization shall meet the `UnaryTypeTrait` requirements (20.10.1). If the template parameter reflects an explicit constructor, the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

18.11.4.21 Destructor operations [reflect.ops.dtor]

```cpp
template <Destructor T> struct is_virtual<T>;
template <Destructor T> struct is_pure_virtual<T>;
```

1

All specializations of these partial template specializations shall meet the `UnaryTypeTrait` requirements (20.10.1). If the template parameter reflects a virtual (for `is_virtual`) or pure virtual (for `is_pure_virtual`) destructor, the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

§ 18.11.4.21 © ISO/IEC 2020 – All rights reserved 45
18.11.4.22 ConversionOperator operations

```cpp
template <ConversionOperator T> struct is_explicit<T>;
```

All specializations of `is_explicit<T>` shall meet the UnaryTypeTrait requirements (20.10.1). If the template parameter reflects an explicit conversion function, the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

18.11.4.23 Lambda operations

```cpp
template <Lambda T> struct get_captures;
```

All specializations of `get_captures<T>` shall meet the TransformationTrait requirements (20.10.1). The nested type named `type` designates a meta-object type satisfying ObjectSequence, containing elements which satisfy LambdaCapture and reflect the captures of the closure object reflected by `T`. The elements are in order of appearance in the `lambda-capture`; captures captured because of a `capture-default` have no defined order among the default captures.

```cpp
template <Lambda T> struct uses_default_copy_capture;
template <Lambda T> struct uses_default_reference_capture;
```

All specializations of these templates shall meet the UnaryTypeTrait requirements (20.10.1). If the template parameter reflects a closure object with a `capture-default` that is `=` (for `uses_default_copy_capture`) or `&` (for `uses_default_reference_capture`), the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

```cpp
template <Lambda T> struct is_call_operator_const;
```

All specializations of `is_call_operator_const<T>` shall meet the UnaryTypeTrait requirements (20.10.1). If the template parameter reflects a closure object with a `const` function call operator, the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

18.11.4.24 LambdaCapture operations

```cpp
template <LambdaCapture T> struct is_explicitly_captured;
```

All specializations of `is_explicitly_captured<T>` shall meet the UnaryTypeTrait requirements (20.10.1). If the template parameter reflects an explicitly captured entity, the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`.

```cpp
template <LambdaCapture T> struct is_init_capture;
```

All specializations of `is_init_capture<T>` shall meet the UnaryTypeTrait requirements (20.10.1). If the template parameter reflects an `init-capture`, the base characteristic of the respective template specialization is `true_type`, otherwise it is `false_type`. 
Annex A (informative)
Compatibility

Modify title for section A.1 to 'C++ extensions for Concepts with Reflection and ISO C++ 2014'.

A.1  C++ extensions for Concepts with Reflection and ISO C++ 2014

In C++ [diff.iso], modify the first paragraph:

This subclause lists the differences between C++ with Reflection and Concepts and ISO C++ by the chapters of this document.

A.1.1 Clause 2: lexical conventions

In C++ [diff.lex], modify the first paragraph:

1  **Affected subclause:** 2.12

**Change:** New keywords.

**Rationale:** Required for new features. The requires keyword is added to introduce constraints through a requires-clause or a requires-expression. The concept keyword is added to enable the definition of concepts (7.1.7). The reflexpr keyword is added to introduce meta-data through a reflexpr-specifier.

**Effect on original feature:** Valid ISO C++ 2014 code using concept or requires or reflexpr as an identifier is not valid in this International Standard.
