1 Introduction

1.1 Background

Most of today's general purpose computing architectures provide binary floating-point arithmetic in hardware. Binary floating-point is an efficient representation which minimizes memory use, and is simpler to implement than floating-point arithmetic using other bases. It has therefore become the norm for scientific computations, with almost all implementations following the IEEE-754 standard for binary floating-point arithmetic.

However, human computation and communication of numeric values almost always uses decimal arithmetic and decimal notations. Laboratory notes, scientific papers, legal documents, business reports and financial statements all record numeric values in decimal form. When numeric data are given to a program or are displayed to a user, binary to-and-from decimal conversion is required. There are inherent rounding errors involved in such conversions; decimal fractions cannot, in general, be represented exactly by binary floating-point values. These errors often cause usability and efficiency problems, depending on the application.

These problems are minor when the application domain accepts, or requires results to have, associated error estimates (as is the case with scientific applications). However, in business and financial applications, computations are either required to be exact (with no rounding errors) unless explicitly rounded, or be supported by detailed analyses that are auditable to be correct. Such applications therefore have to take special care in handling any rounding errors introduced by the computations.

The most efficient way to avoid conversion error is to use decimal arithmetic. Currently, the IBM zArchitecture (and its predecessors since System/360) is a widely used system that supports built-in decimal arithmetic. This, however, provides integer arithmetic only, meaning that every number and computation has to have separate scale information preserved and computed in order to maintain the required precision and value range. Such scaling is difficult to code and is error-prone; it affects execution time significantly, and the resulting program is often difficult to maintain and enhance.

Even though the hardware may not provide decimal arithmetic operations, the support can still be emulated by software. Programming languages used for business applications either have native decimal types (such as PL/I, COBOL, C#, or Visual Basic) or provide decimal arithmetic libraries (such as the BigDecimal class in Java). The arithmetic used, nowadays, is almost invariably decimal floating-point; the COBOL 2002 ISO standard, for example, requires that all standard decimal arithmetic calculations use 32-digit decimal floating-point.

At present, most implementations use software for decimal arithmetic. Even the best packages are slow, and can be 100 times slower than a corresponding hardware implementation, and in some cases much slower. At least one processor manufacturer, therefore, is adding decimal floating-point in hardware.

Arguably, the C language hits a sweet spot within the wide range of programming languages available today – it strikes an optimal balance between usability and performance. Its simple and expressive syntax makes it easy to program; and its close-to-the-hardware semantics makes it efficient. Despite the advent of newer programming languages, C is still often used together with other languages to code the computationally intensive part of an application. In many cases, entire business applications are written in C/C++. To maintain the vitality of C, the need for decimal arithmetic by the business and financial community cannot be ignored.

The importance of this has been recognized by the IEEE. The IEEE 754 standard is currently being revised, and the major change in that revision is the addition of decimal floating-point formats and arithmetic. These decimal data types are almost as efficient as the binary types, and are especially suitable for hardware implementation; it is possible that they will become the most widely used primitive data types once hardware implementations are available.

Historically there has been a close tie between IEEE-754 and C with respect to floating-point specification. This Technical Report proposes to add decimal floating types and arithmetic to the C programming language specification.

1.2 The Arithmetic Model

The proposal of this Technical Report is based on a model of decimal arithmetic¹ which is a formalization of the decimal system of numeration (Algorism) as further defined and constrained by the relevant standards, IEEE-854, ANSI X3-274, and the proposed revision of IEEE-754. The latter is also known as IEEE-754R.

There are three components to the model:

- *numbers* - which represent the values which can be manipulated by, or be the results of, the core operations defined in the model
- *operations* - the core operations (such as addition, multiplication, etc.) which can be carried out on numbers
- *context* - which represents the user-selectable parameters, the status of the operations (for example, any exceptions they caused), and rules which govern the results of arithmetic operations (for example, the rounding mode to be used)

The model defines these components in the abstract. It neither defines the way in which operations are expressed (which might vary depending on the computer language or other interface being used), nor does it define the concrete representation (specific layout in storage, or in a processor's register, for example) of numbers or context.

From the perspective of the C language, *numbers* are represented by data types, *operations* are defined within expressions, and *context* is the floating environment specified in `fenv.h`. This Technical Report specifies how the C language implements these components.

¹ A description of the arithmetic model can be found in <http://www2.hursley.ibm.com/decimal/decarith.html>.

1.3 The Encodings

Based on the arithmetic model, encodings have been proposed to support the general purpose floating-point decimal arithmetic described in the Decimal Arithmetic Specification². The encodings are the product of discussions by a subcommittee of the IEEE committee IEEE-754R which is currently revising the IEEE 754-1985 and IEEE 854-1987 standards.

C99 specifies floating-point arithmetic using a two-layer organization. The first layer provides a specification using an abstract model. The representation of floating-point number is specified in an abstract form where the constituent components of the representation is defined (sign, exponent, significand) but not the internals of these components. In particular, the exponent range, significand size and the base (or radix), are implementation defined. This allows flexibility for an implementation to take advantage of its underlying hardware architecture. Furthermore, certain behaviors of operations are also implementation defined, for example in the area of handling of special numbers and in exceptions.

The reason for this approach is historical. At the time when C was first standardized, there were already various hardware implementations of floating-point arithmetic in common use. Specifying the exact details of a representation would make most of the existing implementations at the time not conforming.

C99 provides a binding to IEEE-754 by specifying an Annex F, *IEC 60559 floating point arithmetic*, and adopting that standard by reference. An implementation may choose not to conform to IEEE-754 and indicates that by not defining the macro `__STDC_IEC_559__`. This means not all implementations need to support IEEE-754, and the floating-point arithmetic need not be binary.

This Technical Report specifies decimal floating-point arithmetic according to the IEEE-754R, with the constituent components of the representation defined. This is more stringent than the existing C99 approach for the floating types. Since it is expected that all decimal floating-point hardware implementations will conform to the revised IEEE 754, binding to this standard directly benefits both implementers and programmers.

2 General

2.1 Scope

This Technical Report specifies an extension to the programming language C, specified by the international standard ISO/IEC 9899:1999. The extension provides support for decimal floating-point arithmetic that is consistent with the specification in IEEE-754R.

² A description of the encodings can be found in <http://www2.hursley.ibm.com/decimal/decbits.html>.

This Technical Report does not specify binary floating-point arithmetic.

2.2 References

The following standards contain provisions which, through reference in this text, constitute provisions of this Technical Report. For dated references, subsequent amendment to, or revisions of, any of these publications do not apply. However, parties to agreements based on this Technical Report are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred applies. Members of IEC and ISO maintain registers of current valid International Standards.

3 Predefined macro name

The following macro name is conditionally defined by the implementation:

`__STDC_DEC_FP__` The integer constant 1, intended to indicate conformance to this technical report.

4 Decimal floating types

This Technical Report introduces three decimal floating types, designated as `_Decimal32`, `_Decimal64` and `_Decimal128`. The set of values of type `_Decimal32` is a subset of the set of values of the type `_Decimal64`; the set of values of the type `_Decimal64` is a subset of the set of values of the type `_Decimal128`.

Within the type hierarchy, decimal floating types are base types, real types and arithmetic types.

The types `float`, `double`, and `long double` are also called generic floating types for the purpose of this Technical Report.

Note: C does not specify a radix for `float`, `double` and `long double`. An implementation can choose the representation of `float`, `double` and `long double` to be the same as the decimal floating types. In any case, the decimal floating types are distinct from `float`, `double` and `long double` regardless of the representation.

Note: This Technical Report does not define decimal complex types or decimal imaginary types. The three complex types remain as `float _Complex`, `double _Complex` and `long double _Complex`, and the three imaginary types remain as `float _Imaginary`, `double _Imaginary` and `long double _Imaginary`.

Following are suggested changes to the C99:

Change the first sentence of 6.2.5#10.

[10] There are three *generic floating types*, designated as **float**, **double** and **long double**.

Add the following paragraphs after 6.2.5#10.

[10a] There are three *decimal floating types*, designated as **_Decimal32**, **_Decimal64** and **_Decimal128**. The set of values of the type **_Decimal32** is a subset of the set of values of the type **_Decimal64**; the set of values of the type **_Decimal64** is a subset of the set of values of the type **_Decimal128**. Decimal floating types are real floating types.

[10b] Together, the generic floating types and the decimal floating types comprise the *real floating types*.

Add the following to 6.7.2 Type specifiers:

type-specifier:

_Decimal32
_Decimal64
_Decimal128

5 Characteristics of decimal floating types <decimalfloat.h>

The header <float.h> defines characteristics of generic floating types. The contents remain unchanged by this Technical Report.

The characteristics of decimal floating types are defined in terms of a model specifying general decimal arithmetic (1.2). The encodings are specified in IEEE-754R (1.3).

The three decimal encoding formats defined in IEEE-754R correspond to the three decimal floating types as follows:

- **_Decimal32** is a *decimal32* number, which is encoded in four consecutive octets (32 bits)
- **_Decimal64** is a *decimal64* number, which is encoded in eight consecutive octets (64 bits)
- **_Decimal128** is a *decimal128* number, which is encoded in 16 consecutive octets (128 bits)

The value of a finite number is given by $(-1)^{\text{sign}} \times \text{coefficient} \times 10^{\text{exponent}}$. Refer to IEEE-754R for details of the format.

These formats are characterized by the length of the coefficient, and the maximum and minimum exponent. The coefficient is not normalized, so trailing zeros are significant; i.e., 1.0 is equal to but can be distinguished from 1.00. The table below shows these characteristics by format:

Format	<u>_Decimal32</u>	<u>_Decimal64</u>	<u>_Decimal128</u>
Coefficient length in digits	7	16	34
Maximum Exponent (E_{max})	96	384	6144
Minimum Exponent (E_{min})	-95	-383	-6143

The new header <decimalfloat.h> defines several macros that expand to various limits and parameters of the decimal floating-types. The names and meaning of these macros are similar to the corresponding macros for generic floating types in <float.h>.

Suggested change to C99:

Add the following after 5.2.4.2.2:

5.2.4.2.2a Characteristics of decimal floating types <decfloat.h>

[1] The characteristics of decimal floating types are defined in terms of the format described in IEEE-754R. The finite numbers are defined by a sign, an exponent (which is a power of ten), and a decimal integer coefficient. The value of a finite number is given by $(-1)^{\text{sign}} \times \text{coefficient} \times 10^{\text{exponent}}$. The macros defined in decfloat.h provide the characteristics of these representations, which is defined in the Decimal Arithmetic Encoding. The prefixes **DEC32_**, **DEC64_**, and **DEC128_** are used to denote the types **_Decimal32**, **_Decimal64**, and **_Decimal128** respectively.

[2] Except for assignment and casts, the values of operations with decimal floating operands and values subject to the usual arithmetic conversions and of decimal floating constants are evaluated to a format whose range and precision may be greater than required by the type. The use of evaluation formats is characterized by the implementation-defined value of **DEC_EVAL_METHOD**:

- 1 indeterminate;
- 0 evaluate all operations and constants just to the range and precision of the type;
- 1 evaluate operations and constants of type **_Decimal32** and **_Decimal64** to the range and precision of the **_Decimal64** type, evaluate **_Decimal128** operations and constants to the range and precision of the **_Decimal128** type;
- 2 evaluate all operations and constants to the range and precision of the **_Decimal128** type.

All other negative values for **DEC_EVAL_METHOD** characterize implementation-defined behavior.

[3] The values given in the following list shall be replaced by constant expressions suitable for use in #if preprocessing directives:

- number of digits in the coefficient

DEC32_MANT_DIG	7
DEC64_MANT_DIG	16
DEC128_MANT_DIG	34

- minimum exponent

DEC32_MIN_EXP	-95
DEC64_MIN_EXP	-383
DEC128_MIN_EXP	-6143

- maximum exponent

DEC32_MAX_EXP	96
----------------------	-----------

[1] When a finite value of generic floating type is converted to an integer type ...

Add the follow paragraph after 6.3.1.4 paragraph 1:

[1a] When a finite value of decimal floating type is converted to an integer type other than **_Bool**, the fractional part is discarded (i.e., the value is truncated toward zero). If the value of the integral part cannot be represented by the integer type, and the integer type is unsigned, the result shall be the largest representable number if the decimal floating point number is positive, or 0 otherwise. If the integer type is signed, the result shall be the most negative or positive number according to the sign of the floating point number.

Change the first sentence of 6.3.1.4 paragraph 2:

[2] When a value of integer type is converted to a generic floating type, ...

Add the following paragraph after 6.3.1.4 paragraph 2:

[2a] When a value of integer type is converted to a decimal floating type, if the value being converted can be represented exactly in the new type, it is unchanged. If the value being converted is in the range of values that can be represented but cannot be represented exactly, the result shall be correctly rounded. If the value being converted is outside the range of values that can be represented, the result is positive or negative infinity depending on the sign of the value being converted, and the “overflow” floating-point exception shall be raised.

6.2 Conversions among decimal floating types, and between decimal floating types and generic floating types

The specification is similar to the existing ones for float, double and long double, except that when the result cannot be represented exactly, the behavior is tightened to become correctly rounded.

Suggested change to C99:

Add after 6.3.1.5#2.

[3] When a **_Decimal32** is promoted to **_Decimal64** or **_Decimal128**, or a **_Decimal64** is promoted to **_Decimal128**, the value is converted to the type being promoted to. All extra precision and/or range (for the new type) are removed.

[4] When a **_Decimal64** is demoted to **_Decimal32**, a **_Decimal128** is demoted to **_Decimal64** or **_Decimal32**, or conversion is performed among decimal and generic floating types other than the above, if the value being converted can be represented exactly in the new type, it is unchanged. If the value being converted is in the range of values that can be represented but cannot be represented exactly, the result is correctly rounded. If the value being converted is outside the

range of values that can be represented, the result is dependent on the rounding mode. If the rounding mode is:

near, if the value being converted is less than the maximum representable value of the target type plus 0.5 ulp, the result is the maximum value of the target type³; otherwise the absolute value of the result is one of **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D64**, **HUGE_VAL_D32** or **HUGE_VAL_D128** depending on the result type and the sign is the same as the value being converted.

zero, the value is the most positive representable if the value being converted is positive, and the most negative number representable otherwise.

positive infinity, the value is same as for rounding mode *zero* if the value being converted is negative; otherwise the result is one of positive **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D64**, **HUGE_VAL_D32** or **HUGE_VAL_D128** depending on the result type.

negative infinity, the value is same as for rounding mode *near* if the value being converted is negative; otherwise the result is one of negative **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D64**, **HUGE_VAL_D32** or **HUGE_VAL_D128** depending on the result type.

6.3 Conversions between decimal floating and complex

When a value of decimal floating type is converted to a complex type, the real part of the complex result value is determined by the rules of conversion in [6.2](#) and the imaginary part of the complex result value is zero.

This is covered by C99 6.3.1.7.

6.4 Usual arithmetic conversions

In an application that is written using decimal arithmetic, mixed operations between decimal and other real types are likely to occur only when interfacing with other languages, calling existing libraries written for binary floating point arithmetic, or accessing existing data. Determining the common type for mixed operations is difficult because ranges overlap; therefore, mixed mode operations are not allowed and the programmer must use explicit casts. Implicit conversions are allowed only for simple assignment and in argument passing.

Following are suggested changes to C99:

³ That is, the values that are between MAX and $MAX+10^{E_{max}}*ulp/2$

Insert the following to 6.3.1.8#1, after "This pattern is called the *usual arithmetic conversions*:"

6.3.1.8[1]

... This pattern is called the *usual arithmetic conversions*:

If one operand is a decimal floating type, all other operands shall not be generic floating type, complex type or imaginary type:

First if either operand is **_Decimal128**, the other operand is converted to **_Decimal128**.

Otherwise, if either operand is **_Decimal64**, the other operand is converted to **_Decimal64**.

Otherwise, if either operand is **_Decimal32**, the other operand is converted to **_Decimal32**.

If there are no decimal floating type in the operands:

First, if the corresponding real type of either operand is **long double**, the other operand is converted, without ... <the rest of 6.3.1.8#1 remains the same>

6.5 Default argument promotion

There is no default argument promotion specified for the decimal floating types. Default argument promotion covered in C99 6.5.2.2 [6] and [7] remains unchanged, and applies to generic floating types only.

7 Constants

New suffixes are added to denote decimal floating constants: DF for **_Decimal32**, DD for **_Decimal64**, and DL for **_Decimal128**.

Suggested changes to C99:

Add the following to 6.4.4.2 floating-suffix.

floating-suffix: one of
f d l F D L df dd dl DF DD DL

Add the following paragraph after 6.4.4.2#2:

6.4.4.2

...

[2a] Constraints

The *floating-suffix* **df**, **dd**, **dl**, **DF**, **DD** and **DL** shall not be used in a *hexadecimal-floating-constant*.

Change 6.4.4.2#4 to:

[4] An unsuffixed floating constant has type double. If suffixed by the letter **f** or **F**, it has type float. If suffixed by the letter **d** or **D**, it has type double. If suffixed by the letter **l** or **L**, it has type long double.

Add the following paragraph after 6.4.4.2#4:

6.4.4.2

...

[4a] If a floating constant is suffixed by **df** or **DF**, it has type `_Decimal32`. If suffixed by **dd** or **DD**, it has type `_Decimal64`. If suffixed by **dl** or **DL**, it has type `_Decimal128`.

7.1 Unsuffixed floating constant

The above introduces new suffixes for the decimal floating constants. It would help usability if unsuffixed floating constant can be used. The issue can be illustrated by the following example:

```
_Decimal64 rate = 0.1;
```

The constant 0.1 has type double. In an implementation where binary representation is used for the floating types, and `FLT_EVAL_METHOD` is not -1, the internal representation of 0.1 cannot be exact. The variable *rate* will get a value slightly different from 0.1. This defeats the purpose of decimal floating types. On the other hand, requiring programmers to write:

```
_Decimal64 rate = 0.1dd;
```

can be inconvenient and affect readability of the program.

7.1.1 Translation time data type

The main idea is to introduce a translation time data type (TTDT) which the translator uses as the type for unsuffixed floating constants. A floating constant is kept in this type and representation until an operation requires it to be converted to an actual type. The value of the constant remains exact for as long as possible during the translation process. The concept can be summarized as follows:

1. The implementation is allowed to use a type different from double and long double as the type of unsuffixed floating constant. This is an implementation defined type. The intention is that

this type can represent the constant exactly if the number of decimal digits is within an implementation specified limit. For an implementation that supports decimal floating point, a possible choice is the widest decimal floating type.

2. The range and precision of this type are implementation defined and are fixed throughout the program.
3. TTDT is an arithmetic type. All arithmetic operations are defined for this type.
4. Usual arithmetic conversion is extended to handle mixed operations between TTDT and other types. If an operation involves both TTDT and an actual type, the TTDT is converted to an actual type before the operation. There is no "top-down" parsing context information required to process unsuffixed floating constants. Technically speaking, there is no deferring in determining the type of the constant.

Examples:

```
double f;
f = 0.1;
```

Suppose the implementation uses `_Decimal128` as the TTDT. 0.1 is represented exactly after the constant is scanned. It is then converted to double in the assignment operator.

```
f = 0.1 * 0.3;
```

Here, both 0.1 and 0.3 are represented in TTDT. If the compiler evaluates the expression during translation time, it would be done using TTDT, and the result would be TTDT. This is then converted to double before the assignment. If the compiler generates code to evaluate the expression during execution time, both 0.1 and 0.3 would be converted to double before the multiply. The result of the former would be different but more precise than the latter.

```
float g = 0.3f;
f = 0.1 * g;
```

When one operand is a TTDT and the other is one of float/double/long double, the TTDT is converted to double with an internal representation following the specification of `FLT_EVAL_METHOD` for constant of type double. Usual arithmetic conversion is then applied to the resulting operands.

```
_Decimal32 h = 0.1;
```

If one operand is a TTDT and the other a decimal floating type, the TTDT is converted to `_Decimal64` with an internal representation specified by `DEC_EVAL_METHOD`. Usual arithmetic conversion is then applied.

If one operand is a TTDT and the other a fixed point type, the TTDT is converted to the fixed point type. If the implementation supports fixed point type, it is a recommended practice that the implementation chooses a representation for TTDT that can represent floating and fixed point constants exactly, subjected to an implementation defined limit on the number of decimal digits.

Suggested changes to C99:

Below are suggested changes to C99. Fixed point types are not considered in these changes.

In 6.2.5 after paragraph 28, add a paragraph:

[28a] There is an implementation defined data type called the *translation time data type*, or *TTDT*. TTDT is an arithmetic type and is used as the type for unsuffixed floating constants. There is no type specifier for TTDT.

Replace 6.4.4.2 paragraph 4 with the following:

[4] An unsuffixed floating constant has type TTDT. If suffixed by the letter **f** or **F**, it has type **float**. If suffixed by the letter **d** or **D**, it has type **double**. If suffixed by the letter **l** or **L**, it has type **long double**.

Add the following paragraphs after 6.3.1.7:

6.3.1.7a Translation Time Data Type

When a TTDT is converted to double, it is converted to the internal representation specified by **FLT_EVAL_METHOD**.

Recommended practice

The conversion of TTDT to double should match the execution-time conversion of character strings by library functions, such as **strtod**, given matching inputs suitable for both conversions, the same format and default execution-time rounding.

6.3.1.7b

Before the *usual arithmetic conversions* are carried out, if one operand is TTDT and the other is not, and is not a decimal floating type, the TTDT operand is converted to double. Otherwise, the behavior is implementation defined.

8 Floating-point environment <fenv.h>

The floating point environment specified in C99 7.6 applies to both generic floating types and decimal floating types. This is to implement the *context* defined in IEEE 754R. The existing C99 specification gives flexibility to implementation on which part of the environment is accessible to programs. The decimal floating-point arithmetic specifies a more stringent requirement. All the rounding directions and flags are supported.

DEC Macros	Existing C99 macros for	IEEE 754
------------	-------------------------	----------

	generic floating types	
FE_DEC_TOWARDZERO	FE_TOWARDZERO	Toward zero
FE_DEC_TONESREST	FE_TONEAREST	To nearest, ties even
FE_DEC_UPWARD	FE_UPWARD	Toward plus infinity
FE_DEC_DOWNWARD	FE_DOWNWARD	Toward minus infinity
FE_DEC_TONEARESTFROMZERO	n/a	To nearest, ties away from zero

Suggested changes to C99:

Add the following after 7.6 paragraph 7:

7.6

...

[7a] Each of the macros

```

FE_DEC_DOWNWARD
FE_DEC_TONEAREST
FE_DEC_TONEARESTFROMZERO
FE_DEC_TOWARDZERO
FE_DEC_UPWARD

```

is defined and used by **fe_dec_getround** and **fe_dec_setround** functions for getting and setting the rounding direction of decimal floating-point operations.

Add the following after 7.6.3.2:

7.6.3.3 The **fe_dec_getround** function

Synopsis

```

#include <fenv.h>
int fe_dec_getround(void);

```

Description

The **fe_dec_getround** function gets the current rounding direction for decimal floating-point operations.

Returns

The **fe_dec_getround** function returns the value of the rounding direction macro representing the current rounding direction for decimal floating-point operations, or a negative value if there is no such rounding macro or the current rounding direction is not determinable.

7.6.3.4 The `fe_dec_setround` function

Synopsis

```
#include <fenv.h>
int fe_dec_setround(int round);
```

Description

The `fe_dec_setround` function establishes the rounding direction for decimal floating-point operations represented by its argument `round`. If the argument is not equal to the value of a rounding direction macro, the rounding direction is not changed.

Returns

The `fe_dec_setround` function returns a zero value if and only if the argument is equal to a rounding direction macro (that is, if and only if the requested rounding direction was established).

8.1 The `DEC_MAX_PRECISION` pragma

Certain algorithms or legal requirements may stipulate a precision on the result of an operation; and this precision could be different from those of the three standard types. A mechanism for the programmer to specify a precision is needed. However, using a library function to control the precision dynamically during execution-time is not efficient. This technical report proposes a translation time control using a pragma directive.

Suggested changes to C99:

Add the following after 7.6.4

7.6.5 The `DEC_MAX_PRECISION` pragma

Synopsis

```
#pragma STDC DEC_MAX_PRECISION integer | DEFAULT
```

Description

The `DEC_MAX_PRECISION` pragma specifies a maximum working precision for decimal floating point operations. After usual arithmetic conversions, if the type of the operands has coefficient length greater than or equal to *integer*, the operation will deliver the result in a precision of *integer*, correctly rounded if necessary. It has no effects on the operation if the coefficient length of the operand type is less than *integer*.

DEFAULT means no special precision is requested. The precision used in an operation is the coefficient length of the type of the operands, after usual arithmetic conversions.

The pragma shall occur either outside external declarations or preceding all explicit declarations and statements inside a compound statement. When outside external declarations, the pragma takes effect from its occurrence until another **DEC_MAX_PRECISION** pragma is encountered, or until the end of the translation unit. When inside a compound statement, the pragma takes effect from its occurrence until another **DEC_MAX_PRECISION** pragma is encountered (including within a nested compound statement), or until the end of the compound statement; at the end of a compound statement the state of the pragma is restored to its condition just before the compound statement. If this pragma is used in any other context, the behavior is undefined. The default state for the pragma is *DEFAULT*.

9 Arithmetic Operations

9.1 Operators

The operators *Add* (C99 6.5.6), *Subtract* (C99 6.5.6), *Multiply* (C99 6.5.5), *Divide* (C99 6.5.5), *Relational operators* (C99 6.5.8), *Equality operators* (C99 6.5.9), *Unary Arithmetic operators* (C99 6.5.3.3), and *Compound Assignment operators* (C99 6.5.16.2) when applied to decimal floating type operands shall follow the semantics as defined in IEEE 754R.

9.2 Functions

The decimal floating point operations square root, min, max, fused multiply-add and remainder, which are defined in IEEE 754R, are implemented as [library](#) functions.

9.3 Conversions

Conversions between different formats and to/from integer formats are covered in [section 6](#).

10 Library

10.1 Decimal mathematics <math.h>

The list of elementary functions specified in the mathematics library is extended to handle decimal floating-point types. These include functions specified in 7.12.4, 7.12.5, 7.12.6, 7.12.7, 7.12.8, 7.12.9, 7.12.10, 7.12.11, 7.12.12, and 7.12.13. The macros `HUGE_VAL_D32`, `HUGE_VAL_D64`, `HUGE_VAL_D128`, `DEC_INFINITY` and `DEC_NAN` are defined to help using these functions. With the exception of `sqrt`, `max`, and `min`, the accuracy of the decimal floating-point results is

implementation-defined. The implementation may state that the accuracy is unknown. All classification macros specified in C99 7.12.3 are also extended to handle decimal floating-point types. The same applies to all comparison macros specified in 7.12.14.

The names of the functions are derived by adding suffixes d32, d64 and d128 to the double version of the function name.

Suggested changes to C99:

Add after 7.12 paragraph 2.

7.12

[2a] The types

_Decimal32_t
_Decimal64_t

are decimal floating types at least as wide as **_Decimal32** and **_Decimal64**, respectively, and such that **_Decimal64_t** is at least as wide as **_Decimal32_t**. If **DEC_EVAL_METHOD** equals 0, **_Decimal32_t** and **_Decimal64_t** are **_Decimal32** and **_Decimal64**, respectively; if **DEC_EVAL_METHOD** equals 1, they are both **_Decimal64**; if **DEC_EVAL_METHOD** equals 2, they are both **_Decimal128**; and for other values of **DEC_EVAL_METHOD**, they are otherwise implementation-defined.

Add at the end of 7.12 paragraph 3 the following macros.

7.12

[3] The macro

HUGE_VAL_D64

expands to a positive **_Decimal64** constant expression, not necessarily representable as a **_Decimal32**, or to a constant expression representing infinity. The macros

HUGE_VAL_D32
HUGE_VAL_D128

are respectively **_Decimal32** and **_Decimal128** analogs of **HUGE_VAL_D64**.

Add at the end of 7.12 paragraph 4 the following macro.

7.12

[4] The macro

DEC_INFINITY

expands to a constant expression of type **_Decimal32** representing infinity.

Add at the end of 7.12 paragraph 5 the following macro.

7.12

[5] The macro

DEC_NAN

expands to quiet decimal floating NaN for the type **_Decimal32**.

Add at the end of 7.12 paragraph 7 the following macro.

7.12

[7] The macro

FP_FAST_FMAD32
FP_FAST_FMAD64
FP_FAST_FMAD128

are, respectively, **_Decimal32**, **_Decimal64** and **_Decimal128** analogs of **FP_FAST_FMA**.

Suggested changes to C99:

Add the following list of function prototypes to the synopsis of the respective subclauses:

7.12.4 Trigonometric functions

_Decimal64 acosd64(**_Decimal64** x);
_Decimal32 acosd32(**_Decimal32** x);
_Decimal128 acosd128(**_Decimal128** x);

_Decimal64 asind64(**_Decimal64** x);
_Decimal32 asind32(**_Decimal32** x);
_Decimal128 asind128(**_Decimal128** x);

_Decimal64 atand64(**_Decimal64** x);
_Decimal32 atand32(**_Decimal32** x);

_Decimal128 atand128(_Decimal128 x);

 _Decimal64 atan2d64(_Decimal64 y, _Decimal64 x);
 _Decimal32 atan2d32(_Decimal32 y, _Decimal32 x);
 _Decimal128 atan2d128(_Decimal128 y, _Decimal128 x);

 _Decimal64 cosd64(_Decimal64 x);
 _Decimal32 cosd32(_Decimal32 x);
 _Decimal128 cosd128(_Decimal128 x);

 _Decimal64 sind64(_Decimal64 x);
 _Decimal32 sind32(_Decimal32 x);
 _Decimal128 sind128(_Decimal128 x);

 _Decimal64 tand64(_Decimal64 x);
 _Decimal32 tand32(_Decimal32 x);
 _Decimal128 tand128(_Decimal128 x);

7.12.5 Hyperbolic functions

_Decimal64 acoshd64(_Decimal64 x);
 _Decimal32 acoshd32(_Decimal32 x);
 _Decimal128 acoshd128(_Decimal128 x);

_Decimal64 nexttowardd64(_Decimal64 x, _Decimal128 y);
_Decimal32 nexttowardd32(_Decimal32 x, _Decimal128 y);
_Decimal128 nexttowardd128(_Decimal128 x, _Decimal128 y);

```

7.12.12 Maximum, minimum, and positive difference functions

```

_Decimal64 fdimd64(_Decimal64 x, _Decimal64 y);
_Decimal32 fdimd32(_Decimal32 x, _Decimal32 y);
_Decimal128 fdimd128(_Decimal128 x, _Decimal128 y);

_Decimal64 fmaxd64(_Decimal64 x, _Decimal64 y);
_Decimal32 fmaxd32(_Decimal32 x, _Decimal32 y);
_Decimal128 fmaxd128(_Decimal128 x, _Decimal128 y);

_Decimal64 fmind64(_Decimal64 x, _Decimal64 y);
_Decimal32 fmind32(_Decimal32 x, _Decimal32 y);
_Decimal128 fmind128(_Decimal128 x, _Decimal128 y);

```

7.12.13 Floating multiply-add

```
_Decimal64 fmad64(_Decimal64 x, _Decimal64 y, _Decimal64 z);
_Decimal32 fmad32(_Decimal32 x, _Decimal32 y, _Decimal32 z);
_Decimal128 fmad128(_Decimal128 x, _Decimal128 y, _Decimal128 z);
```

10.2 New functions

The following are new functions added to math.h.

Suggested addition to C99:

7.12.11.5 The quantize functions

Synopsis

```
#include <math.h>
_Decimal32 quantized32 (_Decimal32 x, _Decimal32 y);
_Decimal64 quantized64 (_Decimal64 x, _Decimal64 y);
_Decimal128 quantized128(_Decimal128 x, _Decimal128 y);
```

Description

The quantize functions set the exponent of argument *x* to the exponent of argument *y*, while attempting to keep the value the same. If the exponent is being increased, the value shall be correctly rounded according to the current rounding mode; if the result does not have the same value as *x*, the “inexact” floating-point exception shall be raised. If the exponent is being decreased and the significand of the result has more digits than the type would allow, the result is NaN and the “invalid” floating-point exception shall be raised. If one or both operands are NaN the result is NaN. Otherwise if only one operand is infinity, the result is NaN and the “invalid” floating-point exception shall be raised. If both operands are infinity, the result is DEC_INFINITY and the sign is the same as *x*. The quantize functions do not signal underflow. Whether the quantize functions signal overflow is implementation-defined.

Returns

The quantize functions return the number which is equal in value (except for any rounding) and sign to *x*, and which has an exponent set to be equal to the exponent of *y*.

7.12.11.6 The samequantum functions

Synopsis

```
#include <math.h>
```

```

_Bool samequantumd32 (_Decimal32 x, _Decimal32 y);
_Bool samequantumd64 (_Decimal64 x, _Decimal64 y);
_Bool samequantumd128 (_Decimal128 x, _Decimal128 y);

```

Description

The samequantum functions determine if the representation exponents of the x and y are the same. If both x and y is NaN, or infinity, they have the same representation exponents; if exactly one operand is infinity or exactly one operand is NaN, they do not have the same representation exponents. The samequantum functions raise no exception.

Returns

The samequantum functions return **true** when x and y have the same representation exponents, **false** otherwise.

10.3 Formatted input/output specifiers

Suggested changes to C99:

Add the following to 7.19.6.1 paragraph 7, to 7.19.6.2 paragraph 11, to 7.24.2.1 paragraph 7, and to 7.24.2.2 paragraph 11:

- H** Specifies that a following e, E, f, F, g, or G conversion specifier applies to a **_Decimal32** argument.
- D** Specifies that a following e, E, f, F, g, or G conversion specifier applies to a **_Decimal64** argument.
- DD** Specifies that a following e, E, f, F, g, or G conversion specifier applies to a **_Decimal128** argument.

Change all occurrences of:

A **double** argument representing ...

in the descriptions for the **e**, **E**, **f**, **F**, **g**, and **G** conversion specifiers in 7.19.6.1 paragraph 8 and 7.24.2.1 paragraph 8 to:

A **double** or decimal floating type argument representing ...

10.4 strtod32, strtod64, and strtod128 functions <stdlib.h>

The specifications of these functions are similar to those of `strtod`, `strtof`, and `strtold` as defined in C99 7.20.1.3. These functions are declared in `<stdlib.h>`. Refer to a discussion of Signaling NaNs in the WG14 paper N1011.

Suggested addition to C99:

7.20.1.5 The `strtod32`, `strtod64`, and `strtod128` functions

Synopsis

```
[#1] #include <stdlib.h>
      _Decimal32 strtod32 (const char * restrict nptr, char ** restrict endptr);
      _Decimal64 strtod64 (const char * restrict nptr, char ** restrict endptr);
      _Decimal128 strtod128(const char * restrict nptr, char ** restrict endptr);
```

Description

[#2] The `strtod32`, `strtod64`, and `strtod128` functions convert the initial portion of the string pointed to by `nptr` to `_Decimal32`, `_Decimal64`, and `_Decimal128` representation, respectively. First, they decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by the `isspace` function), a subject sequence resembling a floating-point constant or representing an infinity or NaN; and a final string of one or more unrecognized characters, including the terminating null character of the input string. Then, they attempt to convert the subject sequence to a floating-point number, and return the result.

[#3] The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- a nonempty sequence of decimal digits optionally containing a decimal-point character, then an optional exponent part as defined in 6.4.4.2;
- `INF` or `INFINITY`, ignoring case
- `NAN` or `NAN(n-char-sequenceopt)`, or `SNAN` or `SNAN(n-char-sequenceopt)`, ignoring case in the `NAN` or `SNAN` part, where:

n-char-sequence:
digit
n-char-sequence digit

The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is not of the expected form.

[#4] If the subject sequence has the expected form for a floating-point number, the sequence of characters starting with the first digit or the decimal-point character (whichever occurs first) is

interpreted as a floating constant according to the rules of 6.4.4.2, except that it is not a hexadecimal floating number, that the decimal-point character is used in place of a period, and that if neither an exponent part nor a decimal-point character appears in a decimal floating point number, an exponent part of the appropriate type with value zero is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the sequence is interpreted as negated. A character sequence **INF** or **INFINITY** is interpreted as an infinity. A character sequence **NAN** or **NAN**(*n-char-sequence_{opt}*), or **SNAN** or **SNAN**(*n-char-sequence_{opt}*), is interpreted as a quiet NaN or signalling NaN respectively; the meaning of the *n-char* sequences is implementation-defined.⁴ A pointer to the final string is stored in the object pointed to by **endptr**, provided that **endptr** is not a null pointer.

[#5] The converted value keeps the precision as the input if possible, and the value may be denormalized. Otherwise, rounding may occur and the value is converted according to F.5 [#3]. Rounding happens after any negation.

[#6] In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

[#7] If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of **nptr** is stored in the object pointed to by **endptr**, provided that **endptr** is not a null pointer.

Recommended practice

[#8] If the subject sequence has the decimal form and at most **DEC128_COEFF_DIG** (defined in `<decfloat.h>`) significant digits, the result should be correctly rounded. If the subject sequence *D* has more than **DEC128_COEFF_DIG** significant digits, consider the two bounding, adjacent decimal strings *L* and *U*, both having **DEC128_COEFF_DIG** significant digits, such that the values of *L*, *D*, and *U* satisfy $L \leq D \leq U$. The result should be one of the (equal or adjacent) values that would be obtained by correctly rounding *L* and *U* according to the current rounding direction, with the extra stipulation that the error with respect to *D* should have a correct sign for the current rounding direction.

Returns

[#9] The functions return the converted value, if any. If no conversion could be performed, the value `+0.E0dd` is returned. If the correct value is outside the range of representable values, plus or minus **HUGE_VAL_D64**, **HUGE_VAL_D32**, or **HUGE_VAL_D128** is returned (according to the return type and sign of the value), and the value of the macro **ERANGE** is stored in **errno**. If the result underflows (7.12.1), the functions return a value whose magnitude is no greater than the smallest normalized positive number in the return type; whether **errno** acquires the value **ERANGE** is implementation-defined.

⁴ An implementation may use the *n-char* sequence to determine extra information to be represented in the NaN's significand. No signal should be raised at the point of returning the signaling NaN.

10.5 wcstod32, wcstod64, and wcstod128 functions <wchar.h>

The specifications of these functions are similar to those of wcstod, wcstof, and wcstold as defined in C99 7.24.4.1.1. They are declared in <wchar.h> . Refer to a discussion of Signaling NaNs in the WG14 paper N1011.

Suggested addition to C99:

7.24.4.1.3 The wcstod32, wcstod64, and wcstod128 functions

Synopsis

```
[#1] #include <wchar.h>
      _Decimal32 wcstod32 (const wchar_t * restrict nptr, wchar_t ** restrict endptr);
      _Decimal64 wcstod64 (const wchar_t * restrict nptr, wchar_t ** restrict endptr);
      _Decimal128 wcstod128(const wchar_t * restrict nptr, wchar_t ** restrict endptr);
```

Description

[#2] The **wcstod32**, **wcstod64**, and **wcstod128** functions convert the initial portion of the wide string pointed to by **nptr** to **_Decimal32**, **_Decimal64**, and **_Decimal128** representation, respectively. First, they decompose the input string into three parts: an initial, possibly empty, sequence of white-space wide characters (as specified by the **iswspace** function), a subject sequence resembling a floating-point constant or representing an infinity or NaN; and a final wide string of one or more unrecognized wide characters, including the terminating null wide character of the input wide string. Then, they attempt to convert the subject sequence to a floating-point number, and return the result.

[#3] The expected form of the subject sequence is an optional plus or minus sign, then one of the following:

- a nonempty sequence of decimal digits optionally containing a decimal-point wide character, then an optional exponent part as defined in 6.4.4.2;
- **INF** or **INFINITY**, ignoring case
- **NAN** or **NAN(*n-wchar-sequence_{opt}*)**, or **SNAN** or **SNAN(*n-wchar-sequence_{opt}*)**, ignoring case in the **NAN** or **SNAN** part, where:

n-wchar-sequence:
digit
n-wchar-sequence digit

The subject sequence is defined as the longest initial subsequence of the input wide string, starting with the first non-white-space wide character, that is of the expected form. The subject sequence contains no wide characters if the input wide string is not of the expected form.

[#4] If the subject sequence has the expected form for a floating-point number, the sequence of wide characters starting with the first digit or the decimal-point wide character (whichever occurs first) is interpreted as a floating constant according to the rules of 6.4.4.2, except that it is not a hexadecimal floating number, that the decimal-point wide character is used in place of a period, and that if neither an exponent part nor a decimal-point wide character appears in a decimal floating point number, an exponent part of the appropriate type with value zero is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the sequence is interpreted as negated. A wide character sequence **INF** or **INFINITY** is interpreted as an infinity. A wide character sequence **NAN** or **NAN**(*n-wchar-sequence_{opt}*), or **SNAN** or **SNAN**(*n-wchar-sequence_{opt}*), is interpreted as a quiet NaN or signalling NaN respectively; the meaning of the *n-wchar* sequences is implementation-defined.⁵ A pointer to the final wide string is stored in the object pointed to by **endptr**, provided that **endptr** is not a null pointer.

[#5] The converted value keeps the precision as the input if possible, and the value may be denormalized. Otherwise, rounding may occur and the value is converted according to F.5 [#3]. Rounding happens after any negation.

[#6] In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

[#7] If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of **nptr** is stored in the object pointed to by **endptr**, provided that **endptr** is not a null pointer.

Recommended practice

[#8] If the subject sequence has the decimal form and at most **DEC128_COEFF_DIG** (defined in `<decfloat.h>`) significant digits, the result should be correctly rounded. If the subject sequence *D* has more than **DEC128_COEFF_DIG** significant digits, consider the two bounding, adjacent decimal strings *L* and *U*, both having **DEC128_COEFF_DIG** significant digits, such that the values of *L*, *D*, and *U* satisfy $L \leq D \leq U$. The result should be one of the (equal or adjacent) values that would be obtained by correctly rounding *L* and *U* according to the current rounding direction, with the extra stipulation that the error with respect to *D* should have a correct sign for the current rounding direction.

Returns

[#9] The functions return the converted value, if any. If no conversion could be performed, the value `+0.E0dd` is returned. If the correct value is outside the range of representable values, plus or minus **HUGE_VAL_D64**, **HUGE_VAL_D32**, or **HUGE_VAL_D128** is returned (according to the return type and sign of the value), and the value of the macro **ERANGE** is stored in **errno**. If the result underflows (7.12.1), the functions return a value whose magnitude is no greater than the

⁵ An implementation may use the *n-char* sequence to determine extra information to be represented in the NaN's significand. No signal should be raised at the point of returning the signaling NaN.

smallest normalized positive number in the return type; whether **errno** acquires the value **ERANGE** is implementation-defined.

10.6 Type-generic macros <tgmath.h>

All new functions added to `math.h` are subjected to the same requirement as specified in C99 7.22 to provide support for *type-generic* macro expansion. When one of the arguments is a decimal floating type, use of the type-generic macro invokes a function whose parameters have the types determined as follows:

If there is more than one real floating type arguments, usual arithmetic conversions are applied to the real floating type arguments so that they have compatible types. Then,

- If any argument has type `_Decimal128`, the type determined is `_Decimal128`.
- Otherwise, if any argument has type `_Decimal64`, the type determined is `_Decimal64`.
- Otherwise, if any argument has type `_Decimal32`, the type determined is `_Decimal32`.
- Otherwise, the specification in C99 7.22 paragraph 3 applies.

Annex A

The following is an alternate suggestion to [usual arithmetic conversions](#) using the *greater-range* rule.

Insert the following to 6.3.1.8#1, after "This pattern is called the *usual arithmetic conversions*:"

6.3.1.8[1]

... This pattern is called the *usual arithmetic conversions*:

If one operand is a decimal floating type and there are no complex types in the operands:

If either operand is **_Decimal128** or **long double**, the other operand is converted to **_Decimal128**.

Otherwise, if either operand is **_Decimal64** or **double**, the other operand is converted to **_Decimal64**.

Otherwise, if either operand is **_Decimal32**, the other operand is converted to **_Decimal32**.

If one operand is a decimal floating type and the other is a complex type, the decimal floating type is converted to the first type in the following list that can represent the value range: **float**, **double**, **long double**. It is converted to **long double** if no type in the list can represent its value range. In either case, the complex type is converted to a type whose corresponding real type is this converted type. Usual arithmetic conversions is then applied to the converted operands.

During any of the above conversions, if the value being converted can be represented exactly in the new type, it is unchanged. If the value being converted is in the range of values that can be represented but cannot be represented exactly, the result is correctly rounded. If the value being converted is outside the range of values that can be represented, the result is dependent on the rounding mode. If the rounding mode is:

near, if the value being converted is less than the maximum representable value of the target type plus 0.5 ulp, the result is the maximum value of the target type⁶; otherwise the absolute value of the result is one of **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D64**, **HUGE_VAL_D32** or **HUGE_VAL_D128** depending on the result type and the sign is the same as the value being converted.

zero, the value is the most positive representable if the value being converted is positive, and the most negative number representable otherwise.

⁶ That is, the values that are between MAX and $MAX+10^{E_{max}}*ulp/2$

positive infinity, the value is same as for rounding mode *zero* if the value being converted is negative; otherwise the result is one of positive **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D64**, **HUGE_VAL_D32** or **HUGE_VAL_D128** depending on the result type.

negative infinity, the value is same as for rounding mode *near* if the value being converted is negative; otherwise the result is one of negative **HUGE_VAL**, **HUGE_VALF**, **HUGE_VALL**, **HUGE_VAL_D64**, **HUGE_VAL_D32** or **HUGE_VAL_D128** depending on the result type.

If there are no decimal floating type in the operands:

First, if the corresponding real type of either operand is **long double**, the other operand is converted, without ... <the rest of 6.3.1.8#1 remains the same>
