## Abstract

This standard defines a standard operating system interface and environment, including a command interpreter (or "shell"), and common utility programs to support applications portability at the source code level. This standard is intended to be used by both applications developers and system implementors and comprises four major components (each in an associated volume):

- General terms, concepts, and interfaces common to all volumes of this standard, including utility conventions and C-language header definitions, are included in the Base Definitions volume.
- Definitions for system service functions and subroutines, language-specific system services for the C programming language, function issues, including portability, error handling, and error recovery, are included in the System Interfaces volume.
- Definitions for a standard source code-level interface to command interpretation services (a "shell") and common utility programs for application programs are included in the Shell and Utilities volume.
- Extended rationale that did not fit well into the rest of the document structure, which contains historical information concerning the contents of this standard and why features were included or discarded by the standard developers, is included in the Rationale (Informative) volume.

The following areas are outside the scope of this standard:

- Graphics interfaces
- Database management system interfaces
- Record I/O considerations
- Object or binary code portability
- System configuration and resource availability

This standard describes the external characteristics and facilities that are of importance to applications developers, rather than the internal construction techniques employed to achieve these capabilities. Special emphasis is placed on those functions and facilities that are needed in a wide variety of commercial applications.

## Keywords

application program interface (API), argument, asynchronous, basic regular expression (BRE), batch job, batch system, built-in utility, byte, child, command language interpreter, CPU, extended regular expression (ERE), FIFO, file access control mechanism input/output (I/O), job control, network, portable operating system interface (POSIX ${ }^{\circledR}$ ), parent, shell, stream, string, synchronous, system, thread, X/Open System Interface (XSI)

## Feedback

This standard has been prepared by the Austin Group. Feedback relating to the material contained in this standard may be submitted using the Austin Group web site at www.opengroup.org/austin/bugreport.html.

## Structure of the Standard

## Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.
This section will be completed in a later draft.

Note: This introduction is not part of IEEE Std 1003.1-200x, Standard for Information Technology Portable Operating System Interface (POSIX).

This draft standard was developed, and is maintained, by a joint working group of members of the IEEE Portable Applications Standards Committee, members of The Open Group, and members of ISO/IEC Joint Technical Committee 1. This joint working group is known as the Austin Group. ${ }^{1}$
The Austin Group arose out of discussions amongst the parties which started in early 1998, leading to an initial meeting and formation of the group in September 1998. The purpose of the Austin Group is to develop and maintain the core open systems interfaces that are the POSIX ${ }^{\circledR}$ 1003.1 (and former 1003.2) standards, ISO/IEC 9945 Parts 1 to 4 , and the core of the Single UNIX Specification.

The approach to specification development has been one of "write once, adopt everywhere", with the deliverables being a set of specifications that carry the IEEE POSIX designation, The Open Group's Technical Standard designation, and an ISO/IEC designation.

This unique development has combined both the industry-led efforts and the formal standardization activities into a single initiative, and included a wide spectrum of participants. The Austin Group continues as the maintenance body for this document.
Anyone wishing to participate in the Austin Group should contact the chair with their request. There are no fees for participation or membership. You may participate as an observer or as a contributor. You do not have to attend face-to-face meetings to participate; electronic participation is most welcome. For more information on the Austin Group and how to participate, see www.opengroup.org/austin.

## Background

The developers of this standard represent a cross section of hardware manufacturers, vendors of operating systems and other software development tools, software designers, consultants, academics, authors, applications programmers, and others.
Conceptually, this standard describes a set of fundamental services needed for the efficient construction of application programs. Access to these services has been provided by defining an interface, using the C programming language, a command interpreter, and common utility programs that establish standard semantics and syntax. Since this interface enables application writers to write portable applications-it was developed with that goal in mind-it has been designated POSIX, ${ }^{2}$ an acronym for Portable Operating System Interface.

Although originated to refer to the original IEEE Std 1003.1-1988, the name POSIX more correctly refers to a family of related standards: IEEE Std 1003.n and the parts of ISO/IEC 9945. In earlier editions of the IEEE standard, the term POSIX was used as a synonym for IEEE Std 1003.1-1988. A preferred term, POSIX.1, emerged. This maintained the advantages of readability of the symbol "POSIX" without being ambiguous with the POSIX family of

[^0]
## Introduction

standards.

## Audience

The intended audience for this standard is all persons concerned with an industry-wide standard operating system based on the UNIX system. This includes at least four groups of people:

1. Persons buying hardware and software systems
2. Persons managing companies that are deciding on future corporate computing directions
3. Persons implementing operating systems, and especially
4. Persons developing applications where portability is an objective

## Purpose

Several principles guided the development of this standard:

- Application-Oriented

The basic goal was to promote portability of application programs across UNIX system environments by developing a clear, consistent, and unambiguous standard for the interface specification of a portable operating system based on the UNIX system documentation. This standard codifies the common, existing definition of the UNIX system.

- Interface, Not Implementation

This standard defines an interface, not an implementation. No distinction is made between library functions and system calls; both are referred to as functions. No details of the implementation of any function are given (although historical practice is sometimes indicated in the RATIONALE section). Symbolic names are given for constants (such as signals and error numbers) rather than numbers.

- Source, Not Object, Portability

This standard has been written so that a program written and translated for execution on one conforming implementation may also be translated for execution on another conforming implementation. This standard does not guarantee that executable (object or binary) code will execute under a different conforming implementation than that for which it was translated, even if the underlying hardware is identical.

- The C Language

The system interfaces and header definitions are written in terms of the standard C language as specified in the ISO C standard.

- No Superuser, No System Administration

There was no intention to specify all aspects of an operating system. System administration facilities and functions are excluded from this standard, and functions usable only by the superuser have not been included. Still, an implementation of the standard interface may also implement features not in this standard. This standard is also not concerned with hardware constraints or system maintenance.

- Minimal Interface, Minimally Defined

In keeping with the historical design principles of the UNIX system, the mandatory core facilities of this standard have been kept as minimal as possible. Additional capabilities have been added as optional extensions.

- Broadly Implementable

The developers of this standard endeavored to make all specified functions implementable across a wide range of existing and potential systems, including:

1. All of the current major systems that are ultimately derived from the original UNIX system code (Version 7 or later)
2. Compatible systems that are not derived from the original UNIX system code
3. Emulations hosted on entirely different operating systems
4. Networked systems
5. Distributed systems
6. Systems running on a broad range of hardware

No direct references to this goal appear in this standard, but some results of it are mentioned in the Rationale (Informative) volume.

- Minimal Changes to Historical Implementations

When the original version-IEEE Std 1003.1-1988-was published, there were no known historical implementations that did not have to change. However, there was a broad consensus on a set of functions, types, definitions, and concepts that formed an interface that was common to most historical implementations.
The adoption of the 1988 and 1990 IEEE system interface standards, the 1992 IEEE shell and utilities standard, the various Open Group (formerly X/Open) specifications, and the 2001 Edition of this standard and its technical corrigenda have have consolidated this consensus, and this revision reflects the significantly increased level of consensus arrived at since the original versions. The authors of the original versions tried, as much as possible, to follow the principles below when creating new specifications:

1. By standardizing an interface like one in an historical implementation; for example, directories
2. By specifying an interface that is readily implementable in terms of, and backwardscompatible with, historical implementations, such as the extended tar format defined in the pax utility
3. By specifying an interface that, when added to an historical implementation, will not conflict with it; for example, the sigaction ( ) function
This standard is specifically not a codification of a particular vendor's product.
It should be noted that implementations will have different kinds of extensions. Some will reflect "historical usage" and will be preserved for execution of pre-existing applications. These functions should be considered "obsolescent" and the standard functions used for new applications. Some extensions will represent functions beyond the scope of this standard. These need to be used with careful management to be able to adapt to future extensions of this standard and/or port to implementations that provide these services in a different manner.

- Minimal Changes to Existing Application Code

A goal of this standard was to minimize additional work for the developers of applications. However, because every known historical implementation will have to change at least slightly to conform, some applications will have to change.

## Introduction

## This Standard

This standard defines the Portable Operating System Interface (POSIX) requirements and consists of the following volumes:

- Base Definitions
- Shell and Utilities (this volume)
- System Interfaces
- Rationale (Informative)

## This Volume

The Shell and Utilities volume describes the commands and utilities offered to application programs on POSIX-conformant systems. Readers are expected to be familiar with the Base Definitions volume.

This volume is structured as follows:

- Chapter 1 explains the status of this volume and its relationship to other formal standards. It also describes the defaults used by the utility descriptions in Chapter 4.
- Chapter 2 describes the command language used in POSIX-conformant systems.
- Chapter 3 describes a set of services and utilities that are implemented on systems supporting the Batch Environment Services and Utilities option.
- Chapter 4 consists of reference pages for all utilities available on POSIX-conformant systems.
Comprehensive references are available in the index.
Typographical Conventions The following typographical conventions are used throughout this standard. In the text, this standard is referred to as IEEE Std 1003.1-200x, which is technically identical to The Open Group Base Specifications, Issue 7.

The typographical conventions listed here are for ease of reading only. Editorial inconsistencies in the use of typography are unintentional and have no normative meaning in this standard.

| Reference | Example | Notes |
| :--- | :--- | :---: |
| C-Language Data Structure | aiocb |  |
| C-Language Data Structure Member | aio_lio_opcode |  |
| C-Language Data Type | long |  |
| errno |  |  |
| C-Language External Variable | system( ) |  |
| C-Language Function | arg1 |  |
| C-Language Function Argument | exec |  |
| C-Language Function Family | <sys/stat.h> |  |
| C-Language Header | return |  |
| C-Language Keyword | assert() |  |
| C-Language Macro with Argument | INET_ADDRSTRLEN |  |
| C-Language Macro with No Argument | \#define |  |
| C-Language Preprocessing Directive | a, c |  |
| Commands within a Utility |  |  |
| Conversion Specification, Specifier/Modifier Character | oA, g, E |  |
| Environment Variable | PATH |  |
| Error Number |  |  |

| Reference | Example | Notes |
| :---: | :---: | :---: |
| Example Output | Hello, World |  |
| Filename | /tmp |  |
| Literal Character | 'c', '\r', '\' | 2 |
| Literal String | "abcde" | 2 |
| Optional Items in Utility Syntax | [ ] |  |
| Parameter | <directory pathname> |  |
| Special Character | <newline> | 3 |
| Symbolic Constant | _POSIX_VDISABLE |  |
| Symbolic Limit, Configuration Value | \{LINE_MAX\} | 4 |
| Syntax | \#include <sys/stat.h> |  |
| User Input and Example Code | echo Hello, World | 5 |
| Utility Name | awk |  |
| Utility Operand | file_name |  |
| Utility Option | -c |  |
| Utility Option with Option-Argument | -w width |  |

## Notes:

1. Conversion specifications, specifier characters, and modifier characters are used primarily in date-related functions and utilities and the fprintf and fscanf formatting functions.
2. Unless otherwise noted, the quotes shall not be used as input or output. When used in a list item, the quotes are omitted. For literal characters, $\backslash \prime$ (or any of the other sequences such as ${ }^{\prime \prime \prime}$ ) is the same as the C constant $\prime^{\prime} \backslash \prime^{\prime}\left(\right.$ or $\left.^{\prime} \backslash \prime \prime\right)$.
3. The style selected for some of the special characters, such as <newline>, matches the form of the input given to the localedef utility. Generally, the characters selected for this special treatment are those that are not visually distinct, such as the control characters <tab> or <newline>.
4. Names surrounded by braces represent symbolic limits or configuration values which may be declared in appropriate headers by means of the C \#define construct.
5. Brackets shown in this font, " [] ", are part of the syntax and do not indicate optional items. In syntax the $y^{\prime}$ symbol is used to separate alternatives, and ellipses (" . . ") are used to show that additional arguments are optional.
Shading is used to identify extensions and options; see Section 1.8 .1 (on page 9).
Footnotes and notes within the body of the normative text are for information only (informative).
Informative sections (such as Rationale, Change History, Application Usage, and so on) are denoted by continuous shading bars in the margins.
Ranges of values are indicated with parentheses or brackets as follows:

- $(a, b)$ means the range of all values from $a$ to $b$, including neither $a$ nor $b$.
- $[a, b]$ means the range of all values from $a$ to $b$, including $a$ and $b$.
- $[a, b)$ means the range of all values from $a$ to $b$, including $a$, but not $b$.
- $(a, b]$ means the range of all values from $a$ to $b$, including $b$, but not $a$.

## Participants

IEEE Std 1003.1-200x was prepared by the Austin Group, sponsored by the Portable Applications Standards Committee of the IEEE Computer Society, The Open Group, and ISO/SC22.

## Notes to Reviewers

This section with side shading will not appear in the final copy. - Ed.
This section will be completed once the standard is approved.

### 1.1 Scope

The scope of IEEE Std 1003.1-200x is described in the Base Definitions volume of IEEE Std 1003.1-200x.

### 1.2 Conformance

Conformance requirements for IEEE Std 1003.1-200x are defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance.

### 1.3 Normative References

Normative references for IEEE Std 1003.1-200x are defined in the Base Definitions volume of IEEE Std 1003.1-200x.

### 1.4 Change History

Change history is described in the Rationale (Informative) volume of IEEE Std 1003.1-200x, and in the CHANGE HISTORY section of reference pages.

### 1.5 Terminology

This section appears in the Base Definitions volume of IEEE Std 1003.1-200x, but is repeated here for convenience:

For the purposes of IEEE Std 1003.1-200x, the following terminology definitions apply:
can
Describes a permissible optional feature or behavior available to the user or application. The feature or behavior is mandatory for an implementation that conforms to IEEE Std 1003.1-200x. An application can rely on the existence of the feature or behavior.
implementation-defined
Describes a value or behavior that is not defined by IEEE Std 1003.1-200x but is selected by an implementor. The value or behavior may vary among implementations that conform to IEEE Std 1003.1-200x. An application should not rely on the existence of the value or behavior. An application that relies on such a value or behavior cannot be assured to be portable across conforming implementations.
The implementor shall document such a value or behavior so that it can be used correctly by an application.

## legacy

Describes a feature or behavior that is being retained for compatibility with older applications, but which has limitations which make it inappropriate for developing portable applications. New applications should use alternative means of obtaining equivalent functionality.

## may

Describes a feature or behavior that is optional for an implementation that conforms to IEEE Std 1003.1-200x. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.
To avoid ambiguity, the opposite of may is expressed as need not, instead of may not.
shall
For an implementation that conforms to IEEE Std 1003.1-200x, describes a feature or behavior that is mandatory. An application can rely on the existence of the feature or behavior.

For an application or user, describes a behavior that is mandatory.

## should

For an implementation that conforms to IEEE Std 1003.1-200x, describes a feature or behavior that is recommended but not mandatory. An application should not rely on the existence of the feature or behavior. An application that relies on such a feature or behavior cannot be assured to be portable across conforming implementations.
For an application, describes a feature or behavior that is recommended programming practice for optimum portability.

## undefined

Describes the nature of a value or behavior not defined by IEEE Std 1003.1-200x which results from use of an invalid program construct or invalid data input.

The value or behavior may vary among implementations that conform to IEEE Std 1003.1-200x. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

## unspecified

Describes the nature of a value or behavior not specified by IEEE Std 1003.1-200x which results from use of a valid program construct or valid data input.
The value or behavior may vary among implementations that conform to IEEE Std 1003.1-200x. An application should not rely on the existence or validity of the value or behavior. An application that relies on any particular value or behavior cannot be assured to be portable across conforming implementations.

### 1.6 Definitions

Concepts and definitions are defined in the Base Definitions volume of IEEE Std 1003.1-200x.

### 1.7 Relationship to Other Documents

### 1.7.1 System Interfaces

This subsection describes some of the features provided by the System Interfaces volume of IEEE Std 1003.1-200x that are assumed to be globally available on all systems conforming to this volume of IEEE Std 1003.1-200x. This subsection does not attempt to detail all of the features defined in the System Interfaces volume of IEEE Std 1003.1-200x that are required by all of the utilities defined in this volume of IEEE Std 1003.1-200x; the utility and function descriptions point out additional functionality required to provide the corresponding specific features needed by each.
The following subsections describe frequently used concepts. Many of these concepts are described in the Base Definitions volume of IEEEStd 1003.1-200x. Utility and function description statements override these defaults when appropriate.

### 1.7.1.1 Process Attributes

The following process attributes, as described in the System Interfaces volume of IEEE Std 1003.1-200x, are assumed to be supported for all processes in this volume of IEEE Std 1003.1-200x:
Controlling Terminal Real Group ID
Current Working Directory
Effective Group ID
Effective User ID
File Descriptors
Real User ID

File Mode Creation Mask
Process Group ID
Root Directory
Saved Set-Group-ID
Saved Set-User-ID

Process ID
Session Membership
Supplementary Group IDs

A conforming implementation may include additional process attributes.

### 1.7.1.2 Concurrent Execution of Processes

The following functionality of the fork () function defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be available on all systems conforming to this volume of IEEE Std 1003.1-200x:

1. Independent processes shall be capable of executing independently without either process terminating.
2. A process shall be able to create a new process with all of the attributes referenced in Section 1.7.1.1 (on page 3), determined according to the semantics of a call to the fork() function defined in the System Interfaces volume of IEEE Std 1003.1-200x followed by a call in the child process to one of the exec functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.

### 1.7.1.3 File Access Permissions

The file access control mechanism described by the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions shall apply to all files on an implementation conforming to this volume of IEEE Std 1003.1-200x.
1.7.1.4 File Read, Write, and Creation

If a file that does not exist is to be written, it shall be created as described below, unless the utility description states otherwise.

When a file that does not exist is created, the following features defined in the System Interfaces volume of IEEE Std 1003.1-200x shall apply unless the utility or function description states otherwise:

1. The user ID of the file shall be set to the effective user ID of the calling process.
2. The group ID of the file shall be set to the effective group ID of the calling process or the group ID of the directory in which the file is being created.
3. If the file is a regular file, the permission bits of the file shall be set to:

S_IROTH \| S_IWOTH \| S_IRGRP | S_IWGRP | S_IRUSR \| S_IWUSR
(see the description of File Modes in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, <sys/stat.h>) except that the bits specified by the file mode creation mask of the process shall be cleared. If the file is a directory, the permission bits shall be set to:

S_IRWXU | S_IRWXG \| S_IRWXO
except that the bits specified by the file mode creation mask of the process shall be cleared.
4. The st_atime, st_ctime, and st_mtime fields of the file shall be updated as specified in the System Interfaces volume of IEEE Std 1003.1-200x, Section 2.5, Standard I/O Streams.
5. If the file is a directory, it shall be an empty directory; otherwise, the file shall have length zero.
6. If the file is a symbolic link, the effect shall be undefined unless the \{POSIX2_SYMLINKS\} variable is in effect for the directory in which the symbolic link would be created.
7. Unless otherwise specified, the file created shall be a regular file.

When an attempt is made to create a file that already exists, the utility shall take the action indicated in Table 1-1 corresponding to the type of the file the utility is trying to create and the type of the existing file, unless the utility description states otherwise.

Table 1-1 Actions when Creating a File that Already Exists

The following codes are used in Table 1-1 (on page 5):
F Fail. The attempt to create the new file shall fail and the utility shall either continue with its operation or exit immediately with a non-zero exit status, depending on the description of the utility.
FL Follow link. Unless otherwise specified, the symbolic link shall be followed as specified for pathname resolution, and the operation performed shall be as if the target of the symbolic link (after all resolution) had been named. If the target of the symbolic link does not exist, it shall be as if that nonexistent target had been named directly.

O Open FIFO. When attempting to create a regular file, and the existing file is a FIFO special file:

1. If the FIFO is not already open for reading, the attempt shall block until the FIFO is opened for reading.
2. Once the FIFO is open for reading, the utility shall open the FIFO for writing and continue with its operation.
OF The named file shall be opened with the consequences defined for that file type.
RF Regular file. When attempting to create a regular file, and the existing file is a regular file:
3. The user ID, group ID, and permission bits of the file shall not be changed.
4. The file shall be truncated to zero length.
5. The st_ctime and st_mtime fields shall be marked for update.

- The effect is implementation-defined unless specified by the utility description.

U The effect is unspecified unless specified by the utility description.

* There is no portable way to create a file of this type.
** Not portable.
When a file is to be appended, the file shall be opened in a manner equivalent to using the O_APPEND flag, without the O_TRUNC flag, in the open() function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

When a file is to be read or written, the file shall be opened with an access mode corresponding
to the operation to be performed. If file access permissions deny access, the requested operation shall fail.

### 1.7.1.5 File Removal

When a directory that is the root directory or current working directory of any process is removed, the effect is implementation-defined. If file access permissions deny access, the requested operation shall fail. Otherwise, when a file is removed:

1. Its directory entry shall be removed from the file system.
2. The link count of the file shall be decremented.
3. If the file is an empty directory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.143, Empty Directory):
a. If no process has the directory open, the space occupied by the directory shall be freed and the directory shall no longer be accessible.
b. If one or more processes have the directory open, the directory contents shall be preserved until all references to the file have been closed.
4. If the file is a directory that is not empty, the st_ctime field shall be marked for update.
5. If the file is not a directory:
a. If the link count becomes zero:
i. If no process has the file open, the space occupied by the file shall be freed and the file shall no longer be accessible.
ii. If one or more processes have the file open, the file contents shall be preserved until all references to the file have been closed.
b. If the link count is not reduced to zero, the st_ctime field shall be marked for update.
6. The st_ctime and st_mtime fields of the containing directory shall be marked for update.

### 1.7.1.6 File Time Values

All files shall have the three time values described by the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.7, File Times Update.

### 1.7.1.7 File Contents

When a reference is made to the contents of a file, pathname, this means the equivalent of all of the data placed in the space pointed to by buf when performing the read () function calls in the following operations defined in the System Interfaces volume of IEEE Std 1003.1-200x:

```
while (read (fildes, buf, nbytes) > 0)
    ;
```

If the file is indicated by a pathname pathname, the file descriptor shall be determined by the equivalent of the following operation defined in the System Interfaces volume of IEEE Std 1003.1-200x:

```
fildes = open (pathname, O_RDONLY);
```

The value of nbytes in the above sequence is unspecified; if the file is of a type where the data returned by read() would vary with different values, the value shall be one that results in the most data being returned.
If the $\operatorname{read}()$ function calls would return an error, it is unspecified whether the contents of the file
are considered to include any data from offsets in the file beyond where the error would be returned.

### 1.7.1.8 Pathname Resolution

The pathname resolution algorithm, described by the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.11, Pathname Resolution, shall be used by implementations conforming to this volume of IEEE Std 1003.1-200x; see also the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.5, File Hierarchy.

### 1.7.1.9 Changing the Current Working Directory

When the current working directory (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.436, Working Directory) is to be changed, unless the utility or function description states otherwise, the operation shall succeed unless a call to the chdir () function defined in the System Interfaces volume of IEEE Std 1003.1-200x would fail when invoked with the new working directory pathname as its argument.
1.7.1.10 Establish the Locale

The functionality of the setlocale() function defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be available on all systems conforming to this volume of IEEE Std 1003.1-200x; that is, utilities that require the capability of establishing an international operating environment shall be permitted to set the specified category of the international environment.
1.7.1.11 Actions Equivalent to Functions

Some utility descriptions specify that a utility performs actions equivalent to a function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Such specifications require only that the external effects be equivalent, not that any effect within the utility and visible only to the utility be equivalent.

### 1.7.2 Concepts Derived from the ISO C Standard

Some of the standard utilities perform complex data manipulation using their own procedure and arithmetic languages, as defined in their EXTENDED DESCRIPTION or OPERANDS sections. Unless otherwise noted, the arithmetic and semantic concepts (precision, type conversion, control flow, and so on) shall be equivalent to those defined in the ISO C standard, as described in the following sections. Note that there is no requirement that the standard utilities be implemented in any particular programming language.
1.7.2.1 Arithmetic Precision and Operations

Integer variables and constants, including the values of operands and option-arguments, used by the standard utilities listed in this volume of IEEE Std 1003.1-200x shall be implemented as equivalent to the ISO C standard signed long data type; floating point shall be implemented as equivalent to the ISO C standard double type. Conversions between types shall be as described in the ISO C standard. All variables shall be initialized to zero if they are not otherwise assigned by the input to the application.
Arithmetic operators and control flow keywords shall be implemented as equivalent to those in the cited ISO C standard section, as listed in Table 1-2 (on page 8).

Table 1-2 Selected ISO C Standard Operators and Control Flow Keywords

| Operation | ISO C Standard Equivalent Reference |
| :---: | :---: |
| () | Section 6.5.1, Primary Expressions |
| $\text { postfix }++$ postfix -- | Section 6.5.2, Postfix Operators |
| unary + unary prefix ++ prefix -- <br> sizeof() | Section 6.5.3, Unary Operators |
| / | Section 6.5.5, Multiplicative Operators |
| $+$ | Section 6.5.6, Additive Operators |
| $\begin{aligned} & \text { << } \\ & \gg \end{aligned}$ | Section 6.5.7, Bitwise Shift Operators |
| $\begin{aligned} & <,<= \\ & >,>= \end{aligned}$ | Section 6.5.8, Relational Operators |
| $\begin{aligned} & == \\ & != \end{aligned}$ | Section 6.5.9, Equality Operators |
| \& | Section 6.5.10, Bitwise AND Operator |
| , | Section 6.5.11, Bitwise Exclusive OR Operator |
| 「 | Section 6.5.12, Bitwise Inclusive OR Operator |
| \& \& | Section 6.5.13, Logical AND Operator |
| 11 | Section 6.5.14, Logical OR Operator |
| expr?expr:expr | Section 6.5.15, Conditional Operator |
| $\begin{aligned} & =, *=, /=, \%=+=,-= \\ & \ll=, \gg=, \&=,=, 1= \end{aligned}$ | Section 6.5.16, Assignment Operators |
| if () if () ... else switch () | Section 6.8.4, Selection Statements |
| ```while () do ... while () for()``` | Section 6.8.5, Iteration Statements |
| goto continue break return | Section 6.8.6, Jump Statements |

The evaluation of arithmetic expressions shall be equivalent to that described in Section 6.5, Expressions, of the ISO C standard.

### 1.7.2.2 Mathematical Functions

Any mathematical functions with the same names as those in the following sections of the ISO C standard:

- Section 7.12, Mathematics, <math . h>
- Section 7.20.2, Pseudo-Random Sequence Generation Functions
shall be implemented to return the results equivalent to those returned from a call to the corresponding function described in the ISO C standard.

## $1.8 \quad$ Portability

Some of the utilities in the Shell and Utilities volume of IEEE Std 1003.1-200x and functions in the System Interfaces volume of IEEE Std 1003.1-200x describe functionality that might not be fully portable to systems meeting the requirements for POSIX conformance (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance).

Where optional, enhanced, or reduced functionality is specified, the text is shaded and a code in the margin identifies the nature of the option, extension, or warning (see Section 1.8.1 (on page 9)). For maximum portability, an application should avoid such functionality.

Unless the primary task of a utility is to produce textual material on its standard output, application developers should not rely on the format or content of any such material that may be produced. Where the primary task is to provide such material, but the output format is incompletely specified, the description is marked with the OF margin code and shading. Application developers are warned not to expect that the output of such an interface on one system is any guide to its behavior on another system.

### 1.8.1 Codes

Codes and their meanings are listed in the Base Definitions volume of IEEE Std 1003.1-200x, but are repeated here for convenience:
ADV Advisory Information
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the ADV margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ADV margin legend.

BE Batch Environment Services and Utilities
The functionality described is optional.
Where applicable, utilities are marked with the BE margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the BE margin legend.
CD C-Language Development Utilities
The functionality described is optional.
Where applicable, utilities are marked with the CD margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the CD margin legend.
CPT Process CPU-Time Clocks
The functionality described is optional. The functionality described is also an extension to the

ISO C standard.
Where applicable, functions are marked with the CPT margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the CPT margin legend.

Extension to the ISO C standard
The functionality described is an extension to the ISO C standard. Application writers may make use of an extension as it is supported on all IEEE Std 1003.1-200x-conforming systems.

With each function or header from the ISO C standard, a statement to the effect that "any conflict is unintentional" is included. That is intended to refer to a direct conflict. IEEE Std 1003.1-200x acts in part as a profile of the ISO

Refer to the Base Definitions volume of IEEE Std 1003.1-200x, Section 1.5.2, Margin Code Notation.

ML Process Memory Locking
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the ML margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the ML margin legend.

MLR Range Memory Locking
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the MLR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MLR margin legend.
mon Monotonic Clock
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MON margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MON margin legend.
msG Message Passing
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MSG margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MSG margin legend.
mx IEC 60559 Floating-Point
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the MX margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the MX margin legend.
Obsolescent
The functionality described may be withdrawn in a future version of this volume of IEEE Std 1003.1-200x. Strictly Conforming POSIX Applications and Strictly Conforming XSI Applications shall not use obsolescent features.

Where applicable, the material is identified by use of the OB margin legend.
of Output Format Incompletely Specified
The functionality described is an XSI extension. The format of the output produced by the utility is not fully specified. It is therefore not possible to post-process this output in a consistent fashion. Typical problems include unknown length of strings and unspecified field delimiters.

Where applicable, the material is identified by use of the OF margin legend.
он Optional Header
In the SYNOPSIS section of some interfaces in the System Interfaces volume of IEEE Std 1003.1-200x an included header is marked as in the following example:

OH \#include <sys/types.h>
\#include <grp.h>
struct group *getgrnam(const char *name);
The OH margin legend indicates that the marked header is not required on XSI-conformant systems.
margin legend.
SIO

Thread CPU-Time Clocks
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TCT margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TCT margin legend.
tef Trace Event Filter
The functionality described is optional. This functionality is dependent on support for the Trace option. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TEF margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TEF margin legend.
TPI Non-Robust Mutex Priority Inheritance
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TPI margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPI margin legend.
TPP Non-Robust Mutex Priority Protection
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TPP margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPP margin legend.
TPS Thread Execution Scheduling
The functionality described is optional. The functionality described is also an extension to the

ISO C standard.
Where applicable, functions are marked with the TPS margin legend for the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TPS margin legend.
trC Trace
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TRC margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRC margin legend.

## Trace Inherit

The functionality described is optional. This functionality is dependent on support for the Trace option. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TRI margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRI margin legend.
trL Trace Log
The functionality described is optional. This functionality is dependent on support for the Trace option. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TRL margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TRL margin legend.
TSA Thread Stack Address Attribute
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSA margin legend for the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSA margin legend.
Thread Process-Shared Synchronization
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSH margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSH margin legend.
Thread Sporadic Server
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TSP margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSP margin legend.
TSS Thread Stack Size Attribute
The functionality described is optional. The functionality described is also an extension to the ISO C standard.
Where applicable, functions are marked with the TSS margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TSS
margin legend.
тYм Typed Memory Objects
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the TYM margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the TYM margin legend.
up User Portability Utilities
The functionality described is optional.
Where applicable, utilities are marked with the UP margin legend in the SYNOPSIS section. Where additional semantics apply to a utility, the material is identified by use of the UP margin legend.

UU UUCP Utilities
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the UU margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the UU margin legend.
xsi X/Open System Interfaces
The functionality described is part of the X/Open Systems Interfaces option. Functionality marked XSI is an extension to the ISO C standard. Application writers may confidently make use of such extensions on all systems supporting the X/Open System Interfaces option.
If an entire SYNOPSIS section is shaded and marked XSI, all the functionality described in that reference page is an extension. See the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.439 , XSI.
xsR XSI STREAMS
The functionality described is optional. The functionality described is also an extension to the ISO C standard.

Where applicable, functions are marked with the XSR margin legend in the SYNOPSIS section. Where additional semantics apply to a function, the material is identified by use of the XSR margin legend.

### 1.9 Utility Limits

This section lists magnitude limitations imposed by a specific implementation. The braces notation, \{LIMIT\}, is used in this volume of IEEE Std 1003.1-200x to indicate these values, but the braces are not part of the name.

Table 1-3 Utility Limit Minimum Values

| Name | Description | Value |
| :---: | :---: | :---: |
| \{POSIX2_BC_BASE_MAX\} | The maximum obase value allowed by the $b c$ utility. | 99 |
| \{POSIX2_BC_DIM_MAX\} | The maximum number of elements permitted in an array by the $b c$ utility. | 2048 |
| \{POSIX2_BC_SCALE_MAX\} | The maximum scale value allowed by the $b c$ utility. | 99 |
| \{POSIX2_BC_STRING_MAX\} | The maximum length of a string constant accepted by the $b c$ utility. | 1000 |
| \{POSIX2_COLL_WEIGHTS_MAX\} | The maximum number of weights that can be assigned to an entry of the LC_COLLATE order keyword in the locale definition file; see the border_start keyword in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.2, LC_COLLATE. | 2 |
| \{POSIX2_EXPR_NEST_MAX\} | The maximum number of expressions that can be nested within parentheses by the expr utility. | 32 |
| \{POSIX2_LINE_MAX\} | Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>. | 2048 |
| \{POSIX2_RE_DUP_MAX\} | The maximum number of repeated occurrences of a BRE permitted when using the interval notation $\backslash\{m, n \backslash\}$; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.6, BREs Matching Multiple Characters. | 255 |

The values specified in Table 1-3 represent the lowest values conforming implementations shall provide and, consequently, the largest values on which an application can rely without further enquiries, as described below. These values shall be accessible to applications via the getconf utility (see getconf (on page 484)).
Implementations may provide more liberal, or less restrictive, values than shown in Table 1-3 (on page 16). These possibly more liberal values are accessible using the symbols in Table 1-4 (on page 17).
The sysconf() function defined in the System Interfaces volume of IEEE Std 1003.1-200x or the getconf utility return the value of each symbol on each specific implementation. The value so retrieved is the largest, or most liberal, value that is available throughout the session lifetime, as determined at session creation. The literal names shown in the table apply only to the getconf utility; the high-level language binding describes the exact form of each name to be used by the interfaces in that binding.
All numeric limits defined by the System Interfaces volume of IEEE Std 1003.1-200x, such as \{PATH_MAX\}, shall also apply to this volume of IEEE Std 1003.1-200x. All the utilities defined by this volume of IEEE Std 1003.1-200x are implicitly limited by these values, unless otherwise noted in the utility descriptions.
It is not guaranteed that the application can actually reach the specified limit of an implementation in any given case, or at all, as a lack of virtual memory or other resources may prevent this. The limit value indicates only that the implementation does not specifically impose any arbitrary, more restrictive limit.

Table 1-4 Symbolic Utility Limits

| Name | Description | Minimum Value |
| :---: | :---: | :---: |
| \{BC_BASE_MAX | The maximum obase value allowed by the $b c$ utility. |  |
| \{BC_DIM_MAX\} | The maximum number of elements permitted in an array by the $b c$ utility. | \{POSIX2_BC_DIM_MAX\} |
| \{BC_SCALE_MAX\} | The maximum scale value allowed by the $b c$ utility. | \{POSIX2_BC_SCALE_MAX\} |
| \{BC_STRING_MAX | The maximum length of a string constant accepted by the $b c$ utility. | \{POSIX2_BC_STRING_MAX\} |
| \{COLL_WEIGHTS_MAX\} | The maximum number of weights that can be assigned to an entry of the LC_COLLATE order keyword in the locale definition file; see the order_start keyword in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3.2, LC_COLLATE. | \{POSIX2_COLL_WEIGHTS_MAX\} |
| \{EXPR_NEST_MAX\} <br> \{LINE_MAX\} | The maximum number of expressions that can be nested within parentheses by the expr utility. <br> Unless otherwise noted, the maximum length, in bytes, of the input line of a utility (either standard input or another file), when the utility is described as processing text files. The length includes room for the trailing <newline>. | \{POSIX2_EXPR_NEST_MAX\} $\text { \{POSIX2_LINE_MAX\} }$ |
| \{RE_DUP_MAX\} | The maximum number of repeated occurrences of a BRE permitted when using the interval notation $\backslash\{m, n \backslash\}$; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.6, BREs Matching Multiple Characters. | \{POSIX2_RE_DUP_MAX\} |

The following value may be a constant within an implementation or may vary from one pathname to another.
\{POSIX2_SYMLINKS\}
When referring to a directory, the system supports the creation of symbolic links within that directory; for non-directory files, the meaning of \{POSIX2_SYMLINKS\} is undefined.

### 1.10 Grammar Conventions

Portions of this volume of IEEE Std 1003.1-200x are expressed in terms of a special grammar notation. It is used to portray the complex syntax of certain program input. The grammar is based on the syntax used by the yacc utility. However, it does not represent fully functional yacc input, suitable for program use; the lexical processing and all semantic requirements are described only in textual form. The grammar is not based on source used in any traditional implementation and has not been tested with the semantic code that would normally be required to accompany it. Furthermore, there is no implication that the partial yacc code presented represents the most efficient, or only, means of supporting the complex syntax within the utility. Implementations may use other programming languages or algorithms, as long as the syntax supported is the same as that represented by the grammar.
The following typographical conventions are used in the grammar; they have no significance except to aid in reading.

- The identifiers for the reserved words of the language are shown with a leading capital letter. (These are terminals in the grammar; for example, While, Case.)
- The identifiers for terminals in the grammar are all named with uppercase letters and underscores; for example, NEWLINE, ASSIGN_OP, NAME.
- The identifiers for non-terminals are all lowercase.

### 1.11 Utility Description Defaults

This section describes all of the subsections used within the utility descriptions, including:

- Intended usage of the section
- Global defaults that affect all the standard utilities
- The meanings of notations used in this volume of IEEE Std 1003.1-200x that are specific to individual utility sections
NAME
This section gives the name or names of the utility and briefly states its purpose.

## SYNOPSIS

The SYNOPSIS section summarizes the syntax of the calling sequence for the utility, including options, option-arguments, and operands. Standards for utility naming are described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines; for describing the utility's arguments in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.1, Utility Argument Syntax.

## DESCRIPTION

The DESCRIPTION section describes the actions of the utility. If the utility has a very complex set of subcommands or its own procedural language, an EXTENDED DESCRIPTION section is also provided. Most explanations of optional functionality are omitted here, as they are usually explained in the OPTIONS section.
As stated in Section 1.7.1.11 (on page 7), some functions are described in terms of equivalent functionality. When specific functions are cited, the implementation shall
provide equivalent functionality including side effects associated with successful execution of the function. The treatment of errors and intermediate results from the individual functions cited is generally not specified by this volume of IEEE Std 1003.1-200x. See the utility's EXIT STATUS and CONSEQUENCES OF ERRORS sections for all actions associated with errors encountered by the utility.

## OPTIONS

The OPTIONS section describes the utility options and option-arguments, and how they modify the actions of the utility. Standard utilities that have options either fully comply with the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines or describe all deviations. Apparent disagreements between functionality descriptions in the OPTIONS and DESCRIPTION (or EXTENDED DESCRIPTION) sections are always resolved in favor of the OPTIONS section.
Each OPTIONS section that uses the phrase "The ... utility shall conform to the Utility Syntax Guidelines ..." refers only to the use of the utility as specified by this volume of IEEE Std 1003.1-200x; implementation extensions should also conform to the guidelines, but may allow exceptions for historical practice.
Unless otherwise stated in the utility description, when given an option unrecognized by the implementation, or when a required option-argument is not provided, standard utilities shall issue a diagnostic message to standard error and exit with a non-zero exit status.

All utilities in this volume of IEEE Std 1003.1-200x shall be capable of processing arguments using eight-bit transparency.
Default Behavior: When this section is listed as "None.", it means that the implementation need not support any options. Standard utilities that do not accept options, but that do accept operands, shall recognize "--" as a first argument to be discarded.

The requirement for recognizing $" ~-~$ " is because conforming applications need a way to shield their operands from any arbitrary options that the implementation may provide as an extension. For example, if the standard utility foo is listed as taking no options, and the application needed to give it a pathname with a leading hyphen, it could safely do it as:
foo - - myfile
and avoid any problems with -m used as an extension.

## OPERANDS

The OPERANDS section describes the utility operands, and how they affect the actions of the utility. Apparent disagreements between functionality descriptions in the OPERANDS and DESCRIPTION (or EXTENDED DESCRIPTION) sections shall be resolved in favor of the OPERANDS section.

If an operand naming a file can be specified as ${ }^{\prime}-{ }^{\prime}$, which means to use the standard input instead of a named file, this is explicitly stated in this section. Unless otherwise stated, the use of multiple instances of $'$ '' to mean standard input in a single command produces unspecified results.
Unless otherwise stated, the standard utilities that accept operands shall process those operands in the order specified in the command line.
Default Behavior: When this section is listed as "None.", it means that the implementation need not support any operands.

## STDIN

The STDIN section describes the standard input of the utility. This section is frequently merely a reference to the following section, as many utilities treat standard input and input files in the same manner. Unless otherwise stated, all restrictions described in the INPUT FILES section shall apply to this section as well.

Use of a terminal for standard input can cause any of the standard utilities that read standard input to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.

The specified standard input format of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of IEEE Std 1003.1-200x, except as provided by this volume of IEEE Std 1003.1-200x.
Default Behavior: When this section is listed as "Not used.", it means that the standard input shall not be read when the utility is used as described by this volume of IEEE Std 1003.1-200x.

## INPUT FILES

The INPUT FILES section describes the files, other than the standard input, used as input by the utility. It includes files named as operands and option-arguments as well as other files that are referred to, such as start-up and initialization files, databases, and so on. Commonly-used files are generally described in one place and cross-referenced by other utilities.
All utilities in this volume of IEEE Std 1003.1-200x shall be capable of processing input files using eight-bit transparency.
When a standard utility reads a seekable input file and terminates without an error before it reaches end-of-file, the utility shall ensure that the file offset in the open file description is properly positioned just past the last byte processed by the utility. For files that are not seekable, the state of the file offset in the open file description for that file is unspecified. A conforming application shall not assume that the following three commands are equivalent:
tail -n +2 file
(sed -n 1q; cat) \& file
cat file (sed -n lq; cat)
The second command is equivalent to the first only when the file is seekable. The third command leaves the file offset in the open file description in an unspecified state. Other utilities, such as head, read, and sh, have similar properties.
Some of the standard utilities, such as filters, process input files a line or a block at a time and have no restrictions on the maximum input file size. Some utilities may have size limitations that are not as obvious as file space or memory limitations. Such limitations should reflect resource limitations of some sort, not arbitrary limits set by implementors. Implementations shall document those utilities that are limited by constraints other than file system space, available memory, and other limits specifically cited by this volume of IEEE Std 1003.1-200x, and identify what the constraint is and indicate a way of estimating when the constraint would be reached. Similarly, some utilities descend the directory tree (recursively). Implementations shall also document any limits that they may have in descending the directory tree that are beyond limits cited by this volume of IEEE Std 1003.1-200x.
When an input file is described as a "text file", the utility produces undefined results if given input that is not from a text file, unless otherwise stated. Some utilities (for example, make, read, sh) allow for continued input lines using an escaped <newline>
convention; unless otherwise stated, the utility need not be able to accumulate more than \{LINE_MAX\} bytes from a set of multiple, continued input lines. Thus, for a conforming application the total of all the continued lines in a set cannot exceed \{LINE_MAX\}. If a utility using the escaped <newline> convention detects an end-offile condition immediately after an escaped <newline>, the results are unspecified.

Record formats are described in a notation similar to that used by the C-language function, $\operatorname{printf(})$. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation for a description of this notation. The format description is intended to be sufficiently rigorous to allow other applications to generate these input files. However, since <blank>s can legitimately be included in some of the fields described by the standard utilities, particularly in locales other than the POSIX locale, this intent is not always realized.
Default Behavior: When this section is listed as "None.", it means that no input files are required to be supplied when the utility is used as described by this volume of IEEE Std 1003.1-200x.

## ENVIRONMENT VARIABLES

The ENVIRONMENT VARIABLES section lists what variables affect the utility's execution.

The entire manner in which environment variables described in this volume of IEEE Std 1003.1-200x affect the behavior of each utility is described in the ENVIRONMENT VARIABLES section for that utility, in conjunction with the global
XSI effects of the $L A N G, L C \_A L L$, and NLSPATH environment variables described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables. The existence or value of environment variables described in this volume of IEEE Std 1003.1-200x shall not otherwise affect the specified behavior of the standard utilities. Any effects of the existence or value of environment variables not described by this volume of IEEE Std 1003.1-200x upon the standard utilities are unspecified.

For those standard utilities that use environment variables as a means for selecting a utility to execute (such as CC in make), the string provided to the utility is subjected to the path search described for PATH in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

All utilities in this volume of IEEE Std 1003.1-200x shall be capable of processing environment variable names and values using eight-bit transparency.
Default Behavior: When this section is listed as "None.", it means that the behavior of the utility is not directly affected by environment variables described by this volume of IEEE Std 1003.1-200x when the utility is used as described by this volume of IEEE Std 1003.1-200x.

## ASYNCHRONOUS EVENTS

The ASYNCHRONOUS EVENTS section lists how the utility reacts to such events as signals and what signals are caught.

Default Behavior: When this section is listed as "Default.", or it refers to "the standard action for all other signals; see Section 1.11 (on page 18)" it means that the action taken as a result of the signal shall be one of the following:

1. The action shall be that inherited from the parent according to the rules of inheritance of signal actions defined in the System Interfaces volume of IEEE Std 1003.1-200x.
2. When no action has been taken to change the default, the default action shall be that specified by the System Interfaces volume of IEEE Std 1003.1-200x.
3. The result of the utility's execution is as if default actions had been taken.

A utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

## STDOUT

The STDOUT section completely describes the standard output of the utility. This section is frequently merely a reference to the following section, OUTPUT FILES, because many utilities treat standard output and output files in the same manner.
Use of a terminal for standard output may cause any of the standard utilities that write standard output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.
Record formats are described in a notation similar to that used by the C-language function, $\operatorname{printf().See~the~Base~Definitions~volume~of~IEEE~Std~1003.1-200x,~Chapter~5,~}$ File Format Notation for a description of this notation.

The specified standard output of the standard utilities shall not depend on the existence or value of the environment variables defined in this volume of IEEE Std 1003.1-200x, except as provided by this volume of IEEE Std 1003.1-200x.
Some of the standard utilities describe their output using the verb display, defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.132, Display. Output described in the STDOUT sections of such utilities may be produced using means other than standard output. When standard output is directed to a terminal, the output described shall be written directly to the terminal. Otherwise, the results are undefined.
Default Behavior: When this section is listed as "Not used.", it means that the standard output shall not be written when the utility is used as described by this volume of IEEE Std 1003.1-200x.

## STDERR

The STDERR section describes the standard error output of the utility. Only those messages that are purposely sent by the utility are described.

Use of a terminal for standard error may cause any of the standard utilities that write standard error output to stop when used in the background. For this reason, applications should not use interactive features in scripts to be placed in the background.
The format of diagnostic messages for most utilities is unspecified, but the language and cultural conventions of diagnostic and informative messages whose format is unspecified by this volume of IEEE Std 1003.1-200x should be affected by the setting of LC_MESSAGES and NLSPATH.

The specified standard error output of standard utilities shall not depend on the existence or value of the environment variables defined in this volume of IEEE Std 1003.1-200x, except as provided by this volume of IEEE Std 1003.1-200x.
Default Behavior: When this section is listed as "The standard error shall be used only for diagnostic messages.", it means that, unless otherwise stated, the diagnostic messages shall be sent to the standard error only when the exit status is non-zero and the utility is used as described by this volume of IEEE Std 1003.1-200x.
When this section is listed as "Not used.", it means that the standard error shall not be
used when the utility is used as described in this volume of IEEE Std 1003.1-200x.

## OUTPUT FILES

The OUTPUT FILES section completely describes the files created or modified by the utility. Temporary or system files that are created for internal usage by this utility or other parts of the implementation (for example, spool, log, and audit files) are not described in this, or any, section. The utilities creating such files and the names of such files are unspecified. If applications are written to use temporary or intermediate files, they should use the TMPDIR environment variable, if it is set and represents an accessible directory, to select the location of temporary files.

Implementations shall ensure that temporary files, when used by the standard utilities, are named so that different utilities or multiple instances of the same utility can operate simultaneously without regard to their working directories, or any other process characteristic other than process ID. There are two exceptions to this rule:

1. Resources for temporary files other than the name space (for example, disk space, available directory entries, or number of processes allowed) are not guaranteed.
2. Certain standard utilities generate output files that are intended as input for other utilities (for example, lex generates lex.yy.c), and these cannot have unique names. These cases are explicitly identified in the descriptions of the respective utilities.
Any temporary file created by the implementation shall be removed by the implementation upon a utility's successful exit, exit because of errors, or before termination by any of the SIGHUP, SIGINT, or SIGTERM signals, unless specified otherwise by the utility description.
Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.
Record formats are described in a notation similar to that used by the C-language function, $\operatorname{printf}()$; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation for a description of this notation.

Default Behavior: When this section is listed as "None.", it means that no files are created or modified as a consequence of direct action on the part of the utility when the utility is used as described by this volume of IEEE Std 1003.1-200x. However, the utility may create or modify system files, such as log files, that are outside the utility's normal execution environment.

## EXTENDED DESCRIPTION

The EXTENDED DESCRIPTION section provides a place for describing the actions of very complicated utilities, such as text editors or language processors, which typically have elaborate command languages.

Default Behavior: When this section is listed as "None.", no further description is necessary.

## EXIT STATUS

The EXIT STATUS section describes the values the utility shall return to the calling program, or shell, and the conditions that cause these values to be returned. Usually, utilities return zero for successful completion and values greater than zero for various error conditions. If specific numeric values are listed in this section, the system shall use those values for the errors described. In some cases, status values are listed more loosely, such as $>0$. A strictly conforming application shall not rely on any specific
value in the range shown and shall be prepared to receive any value in the range.
For example, a utility may list zero as a successful return, 1 as a failure for a specific reason, and $>1$ as "an error occurred". In this case, unspecified conditions may cause a 2 or 3 , or other value, to be returned. A conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in this volume of IEEE Std 1003.1-200x. In that way, it has maximum portability, even on implementations with extensions.

Unspecified error conditions may be represented by specific values not listed in this volume of IEEE Std 1003.1-200x.

## CONSEQUENCES OF ERRORS

The CONSEQUENCES OF ERRORS section describes the effects on the environment, file systems, process state, and so on, when error conditions occur. It does not describe error messages produced or exit status values used.
The many reasons for failure of a utility are generally not specified by the utility descriptions. Utilities may terminate prematurely if they encounter: invalid usage of options, arguments, or environment variables; invalid usage of the complex syntaxes expressed in EXTENDED DESCRIPTION sections; difficulties accessing, creating, reading, or writing files; or difficulties associated with the privileges of the process.
The following shall apply to each utility, unless otherwise stated:

- If the requested action cannot be performed on an operand representing a file, directory, user, process, and so on, the utility shall issue a diagnostic message to standard error and continue processing the next operand in sequence, but the final exit status shall be returned as non-zero.
For a utility that recursively traverses a file hierarchy (such as find or chown -R), if the requested action cannot be performed on a file or directory encountered in the hierarchy, the utility shall issue a diagnostic message to standard error and continue processing the remaining files in the hierarchy, but the final exit status shall be returned as non-zero.
- If the requested action characterized by an option or option-argument cannot be performed, the utility shall issue a diagnostic message to standard error and the exit status returned shall be non-zero.
- When an unrecoverable error condition is encountered, the utility shall exit with a non-zero exit status.
- A diagnostic message shall be written to standard error whenever an error condition occurs.
When a utility encounters an error condition several actions are possible, depending on the severity of the error and the state of the utility. Included in the possible actions of various utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; validity checking of the file system or directory.
Default Behavior: When this section is listed as "Default.", it means that any changes to the environment are unspecified.

## APPLICATION USAGE

This section is informative.
The APPLICATION USAGE section gives advice to the application programmer or user about the way the utility should be used.

## EXAMPLES

This section is informative.
The EXAMPLES section gives one or more examples of usage, where appropriate. In the event of conflict between an example and a normative part of the specification, the normative material is to be taken as correct.

In all examples, quoting has been used, showing how sample commands (utility names combined with arguments) could be passed correctly to a shell (see sh) or as a string to the system () function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Such quoting would not be used if the utility is invoked using one of the exec functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.

## RATIONALE

This section is informative.
This section contains historical information concerning the contents of this volume of IEEE Std 1003.1-200x and why features were included or discarded by the standard developers.

## FUTURE DIRECTIONS

This section is informative.
The FUTURE DIRECTIONS section should be used as a guide to current thinking; there is not necessarily a commitment to implement all of these future directions in their entirety.

## SEE ALSO

This section is informative.
The SEE ALSO section lists related entries.

## CHANGE HISTORY

This section is informative.
This section shows the derivation of the entry and any significant changes that have been made to it.

Certain of the standard utilities describe how they can invoke other utilities or applications, such as by passing a command string to the command interpreter. The external influences (STDIN, ENVIRONMENT VARIABLES, and so on) and external effects (STDOUT, CONSEQUENCES OF ERRORS, and so on) of such invoked utilities are not described in the section concerning the standard utility that invokes them.

### 1.12 Considerations for Utilities in Support of Files of Arbitrary Size

The following utilities support files of any size up to the maximum that can be created by the implementation. This support includes correct writing of file size-related values (such as file sizes and offsets, line numbers, and block counts) and correct interpretation of command line arguments that contain such values.

| basename | Return non-directory portion of pathname. |
| :---: | :---: |
| cat | Concatenate and print files. |
| cd | Change working directory. |
| chgrp | Change file group ownership. |
| chmod | Change file modes. |
| chown | Change file ownership. |
| cksum | Write file checksums and sizes. |
| cmp | Compare two files. |
| cp | Copy files. |
| $d d$ | Convert and copy a file. |
| df | Report free disk space. |
| dirname | Return directory portion of pathname. |
| $d u$ | Estimate file space usage. |
| find | Find files. |
| $l n$ | Link files. |
|  | List directory contents. |
| mkdir <br> mv | Make directories. <br> Move files. |
| pathchk | Check pathnames. |
| pwd | Return working directory name. |
| $r m$ | Remove directory entries. |
| rmdir | Remove directories. |
| sh | Shell, the standard command language interpreter. |
| sum | Print checksum and block or byte count of a file. |
| test | Evaluate expression. |
| touch | Change file access and modification times. |
| ulimit | Set or report file size limit. |

Exceptions to the requirement that utilities support files of any size up to the maximum are as follows:

1. Uses of files as command scripts, or for configuration or control, are exempt. For example, it is not required that sh be able to read an arbitrarily large .profile.
2. Shell input and output redirection are exempt. For example, it is not required that the redirections sum < file or echo foo > file succeed for an arbitrarily large existing file.

### 1.13 Built-In Utilities

Any of the standard utilities may be implemented as regular built-in utilities within the command language interpreter. This is usually done to increase the performance of frequently used utilities or to achieve functionality that would be more difficult in a separate environment. The utilities named in Table 1-5 are frequently provided in built-in form. All of the utilities named in the table have special properties in terms of command search order within the shell, as described in Section 2.9.1.1 (on page 48).

Table 1-5 Regular Built-In Utilities

However, all of the standard utilities, including the regular built-ins in the table, but not the special built-ins described in Section 2.14 (on page 64), shall be implemented in a manner so that they can be accessed via the exec family of functions as defined in the System Interfaces volume of IEEE Std 1003.1-200x and can be invoked directly by those standard utilities that require it (env, find, nice, nohup, time, xargs).

This chapter contains the definition of the Shell Command Language.

### 2.1 Shell Introduction

The shell is a command language interpreter. This chapter describes the syntax of that command language as it is used by the sh utility and the system() and popen() functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.
The shell operates according to the following general overview of operations. The specific details are included in the cited sections of this chapter.

1. The shell reads its input from a file (see sh), from the -c option or from the system () and popen () functions defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the first line of a file of shell commands starts with the characters "\#!", the results are unspecified.
2. The shell breaks the input into tokens: words and operators; see Section 2.3 (on page 31).
3. The shell parses the input into simple commands (see Section 2.9.1 (on page 47)) and compound commands (see Section 2.9.4 (on page 52)).
4. The shell performs various expansions (separately) on different parts of each command, resulting in a list of pathnames and fields to be treated as a command and arguments; see Section 2.6 (on page 37 ).
5. The shell performs redirection (see Section 2.7 (on page 43)) and removes redirection operators and their operands from the parameter list.
6. The shell executes a function (see Section 2.9.5 (on page 54)), built-in (see Section 2.14 (on page 64)), executable file, or script, giving the names of the arguments as positional parameters numbered 1 to $n$, and the name of the command (or in the case of a function within a script, the name of the script) as the positional parameter numbered 0 (see Section 2.9.1.1 (on page 48)).
7. The shell optionally waits for the command to complete and collects the exit status (see Section 2.8.2 (on page 46)).

### 2.2 Quoting

Quoting is used to remove the special meaning of certain characters or words to the shell. Quoting can be used to preserve the literal meaning of the special characters in the next paragraph, prevent reserved words from being recognized as such, and prevent parameter expansion and command substitution within here-document processing (see Section 2.7.4 (on page 44)).
The application shall quote the following characters if they are to represent themselves:
| \& ; < > ( ) \$ ' \ " ' <space> <tab> <newline>
and the following may need to be quoted under certain circumstances. That is, these characters may be special depending on conditions described elsewhere in this volume of IEEE Std 1003.1-200x:

* ? [ \# ~ = \%

The various quoting mechanisms are the escape character, single-quotes, and double-quotes. The here-document represents another form of quoting; see Section 2.7.4 (on page 44).

### 2.2.1 Escape Character (Backslash)

A backslash that is not quoted shall preserve the literal value of the following character, with the exception of a <newline>. If a <newline> follows the backslash, the shell shall interpret this as line continuation. The backslash and <newline>s shall be removed before splitting the input into tokens. Since the escaped <newline> is removed entirely from the input and is not replaced by any white space, it cannot serve as a token separator.

### 2.2.2 Single-Quotes

Enclosing characters in single-quotes ( $\left(^{\prime}\right.$ ) shall preserve the literal value of each character within the single-quotes. A single-quote cannot occur within single-quotes.

### 2.2.3 Double-Quotes

Enclosing characters in double-quotes (" ") shall preserve the literal value of all characters within the double-quotes, with the exception of the characters dollar sign, backquote, and backslash, as follows:
\$ The dollar sign shall retain its special meaning introducing parameter expansion (see Section 2.6.2 (on page 38)), a form of command substitution (see Section 2.6.3 (on page 40)), and arithmetic expansion (see Section 2.6.4 (on page 41)).
The input characters within the quoted string that are also enclosed between "\$(" and the matching ')' shall not be affected by the double-quotes, but rather shall define that command whose output replaces the "\$(...)" when the word is expanded. The tokenizing rules in Section 2.3 (on page 31), not including the alias substitutions in Section 2.3.1 (on page 32), shall be applied recursively to find the matching ' )'.

Within the string of characters from an enclosed " $\$\{$ " to the matching ' $\}$ ', an even number of unescaped double-quotes or single-quotes, if any, shall occur. A preceding backslash character shall be used to escape a literal ' $\{$ ' or ' $\}$ '. The rule in Section 2.6 .2 shall be used to determine the matching ' $\}^{\prime}$.

- The backquote shall retain its special meaning introducing the other form of command substitution (see Section 2.6 .3 (on page 40)). The portion of the quoted string from the initial backquote and the characters up to the next backquote that is not preceded by a backslash, having escape characters removed, defines that command whose output replaces " `. . . '" when the word is expanded. Either of the following cases produces undefined results:
- A single-quoted or double-quoted string that begins, but does not end, within the " `. . . '" sequence
- A " `. . . '" sequence that begins, but does not end, within the same double-quoted string
\ The backslash shall retain its special meaning as an escape character (see Section 2.2.1 (on page 30)) only when followed by one of the following characters when considered special:

The application shall ensure that a double-quote is preceded by a backslash to be included within double-quotes. The parameter ' ${ }^{\prime}$ ' has special meaning inside double-quotes and is described in Section 2.5.2 (on page 34).

### 2.3 Token Recognition

The shell shall read its input in terms of lines from a file, from a terminal in the case of an interactive shell, or from a string in the case of sh -c or system(). The input lines can be of unlimited length. These lines shall be parsed using two major modes: ordinary token recognition and processing of here-documents.
When an io_here token has been recognized by the grammar (see Section 2.10 (on page 55)), one or more of the subsequent lines immediately following the next NEWLINE token form the body of one or more here-documents and shall be parsed according to the rules of Section 2.7.4 (on page 44).
When it is not processing an io_here, the shell shall break its input into tokens by applying the first applicable rule below to the next character in its input. The token shall be from the current position in the input until a token is delimited according to one of the rules below; the characters forming the token are exactly those in the input, including any quoting characters. If it is indicated that a token is delimited, and no characters have been included in a token, processing shall continue until an actual token is delimited.

1. If the end of input is recognized, the current token shall be delimited. If there is no current token, the end-of-input indicator shall be returned as the token.
2. If the previous character was used as part of an operator and the current character is not quoted and can be used with the current characters to form an operator, it shall be used as part of that (operator) token.
3. If the previous character was used as part of an operator and the current character cannot be used with the current characters to form an operator, the operator containing the previous character shall be delimited.
4. If the current character is backslash, single-quote, or double-quote (' ${ }^{\prime} \prime^{\prime} \prime^{\prime \prime}$ ', or ${ }^{\prime \prime \prime \prime}$ ) and it is not quoted, it shall affect quoting for subsequent characters up to the end of the quoted text. The rules for quoting are as described in Section 2.2 (on page 30). During token recognition no substitutions shall be actually performed, and the result token shall contain exactly the characters that appear in the input (except for <newline> joining), unmodified, including any embedded or enclosing quotes or substitution operators, between the quote mark and the end of the quoted text. The token shall not be delimited by the end of the quoted field.
5. If the current character is an unquoted ' $\$$ ' or ' $'$ ', the shell shall identify the start of any candidates for parameter expansion (Section 2.6 .2 (on page 38)), command substitution (Section 2.6 .3 (on page 40)), or arithmetic expansion (Section 2.6 .4 (on page 41)) from their introductory unquoted character sequences: '\$' or "\$\{", "\$(" or ' ', and "\$((",
respectively. The shell shall read sufficient input to determine the end of the unit to be expanded (as explained in the cited sections). While processing the characters, if instances of expansions or quoting are found nested within the substitution, the shell shall recursively process them in the manner specified for the construct that is found. The characters found from the beginning of the substitution to its end, allowing for any recursion necessary to recognize embedded constructs, shall be included unmodified in the result token, including any embedded or enclosing substitution operators or quotes. The token shall not be delimited by the end of the substitution.
6. If the current character is not quoted and can be used as the first character of a new operator, the current token (if any) shall be delimited. The current character shall be used as the beginning of the next (operator) token.
7. If the current character is an unquoted <newline>, the current token shall be delimited.
8. If the current character is an unquoted <blank>, any token containing the previous character is delimited and the current character shall be discarded.
9. If the previous character was part of a word, the current character shall be appended to that word.
10. If the current character is a ${ }^{\prime} \#^{\prime}$, it and all subsequent characters up to, but excluding, the next <newline> shall be discarded as a comment. The <newline> that ends the line is not considered part of the comment.
11. The current character is used as the start of a new word.

Once a token is delimited, it is categorized as required by the grammar in Section 2.10 (on page 55).

### 2.3.1 Alias Substitution

After a token has been delimited, but before applying the grammatical rules in Section 2.10 (on page 55), a resulting word that is identified to be the command name word of a simple command shall be examined to determine whether it is an unquoted, valid alias name. However, reserved words in correct grammatical context shall not be candidates for alias substitution. A valid alias name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.10, Alias Name) shall be one that has been defined by the alias utility and not subsequently undefined using unalias. Implementations also may provide predefined valid aliases that are in effect when the shell is invoked. To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word shall be replaced by the value of the alias; otherwise, it shall not be replaced.
If the value of the alias replacing the word ends in a <blank>, the shell shall check the next command word for alias substitution; this process shall continue until a word is found that is not a valid alias or an alias yalue does not end in a <blank>.
When used as specified by this volume of IEEE Std 1003.1-200x, alias definitions shall not be inherited by separate invocations of the shell or by the utility execution environments invoked by the shell; see Section 2.12 (on page 61 ).

### 2.4 Reserved Words

Reserved words are words that have special meaning to the shell; see Section 2.9 (on page 47). The following words shall be recognized as reserved words:

| $!$ | do | esac | in |
| :--- | :--- | :--- | :--- |
| $\{$ | done | fi | then |
| $\}$ | elif | for | until |
| case | else | if | while |

This recognition shall only occur when none of the characters is quoted and when the word is used as:

- The first word of a command
- The first word following one of the reserved words other than case, for, or in
- The third word in a case command (only in is valid in this case)
- The third word in a for command (only in and do are valid in this case)

See the grammar in Section 2.10 (on page 55).
The following words may be recognized as reserved words on some implementations (when none of the characters are quoted), causing unspecified results:
[ [
]]
function
select
Words that are the concatenation of a name and a colon (' $\left.:^{\prime}\right)$ are reserved; their use produces unspecified results.

### 2.5 Parameters and Variables

A parameter can be denoted by a name, a number, or one of the special characters listed in Section 2.5.2 (on page 34). A variable is a parameter denoted by a name.
A parameter is set if it has an assigned value (null is a valid value). Once a variable is set, it can only be unset by using the unset special built-in command.

### 2.5.1 Positional Parameters

A positional parameter is a parameter denoted by the decimal value represented by one or more digits, other than the single digit 0 . The digits denoting the positional parameters shall always be interpreted as a decimal value, even if there is a leading zero. When a positional parameter with more than one digit is specified, the application shall enclose the digits in braces (see Section 2.6.2 (on page 38)). Positional parameters are initially assigned when the shell is invoked (see $s h$ ), temporarily replaced when a shell function is invoked (see Section 2.9.5 (on page 54)), and can be reassigned with the set special built-in command.

### 2.5.2 Special Parameters

Listed below are the special parameters and the values to which they shall expand. Only the values of the special parameters are listed; see Section 2.6 for a detailed summary of all the stages involved in expanding words.
@ Expands to the positional parameters, starting from one. When the expansion occurs within double-quotes, and where field splitting (see Section 2.6 .5 (on page 42)) is performed, each positional parameter shall expand as a separate field, with the provision that the expansion of the first parameter shall still be joined with the beginning part of the original word (assuming that the expanded parameter was embedded within a word), and the expansion of the last parameter shall still be joined with the last part of the original word. If there are no positional parameters, the expansion of ' @' shall generate zero fields, even when ' $@$ ' is double-quoted.

* Expands to the positional parameters, starting from one. When the expansion occurs within a double-quoted string (see Section 2.2.3 (on page 30)), it shall expand to a single field with the value of each parameter separated by the first character of the IFS variable, or by a <space> if IFS is unset. If IFS is set to a null string, this is not equivalent to unsetting it; its first character does not exist, so the parameter values are concatenated.
\# Expands to the decimal number of positional parameters. The command name (parameter 0 ) shall not be counted in the number given by ' \#' because it is a special parameter, not a positional parameter.
? Expands to the decimal exit status of the most recent pipeline (see Section 2.9.2 (on page 49)).
- (Hyphen.) Expands to the current option flags (the single-letter option names concatenated into a string) as specified on invocation, by the set special built-in command, or implicitly by the shell.
\$ Expands to the decimal process ID of the invoked shell. In a subshell (see Section 2.12 (on page 61)), ' $\$$ ' shall expand to the same value as that of the current shell.
! Expands to the decimal process ID of the most recent background command (see Section 2.9.3 (on page 50)) executed from the current shell. (For example, background commands executed from subshells do not affect the value of "\$!" in the current shell environment.) For a pipeline, the process ID is that of the last command in the pipeline.
0 (Zero.) Expands to the name of the shell or shell script. See sh for a detailed description of how this name is derived.
See the description of the IFS variable in Section 2.5.3 (on page 34).

### 2.5.3 Shell Variables

Variables shall be initialized from the environment (as defined by the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables and the exec function in the System Interfaces volume of IEEE Std 1003.1-200x) and can be given new values with variable assignment commands. If a variable is initialized from the environment, it shall be marked for export immediately; see the export special built-in. New variables can be defined and initialized with variable assignments, with the read or getopts utilities, with the name parameter in a for loop, with the $\$\{$ name=word $\}$ expansion, or with other mechanisms provided as implementation extensions.
The following variables shall affect the execution of the shell:

| 1340 | UP xSIENV <br> 1341 <br> 1342 |
| :--- | :--- |
| The processing of the ENV shell variable shall be supported on all XSI- <br> conformant systems or if the system supports the User Portability Utilities |  |
| option. |  |

| 1386 | xSI | NLSPATH | Determine the location of message catalogs for the processing of |
| :---: | :---: | :---: | :---: |
| 1387 |  |  | LC_MESSAGES. |
| 1388 |  | PATH | A string formatted as described in the Base Definitions volume of |
| 1389 |  |  | IEEE Std 1003.1-200x, Chapter 8, Environment Variables, used to effect |
| 1390 |  |  | command interpretation; see Section 2.9.1.1 (on page 48). |
| 1391 |  | PPID | Set by the shell to the decimal process ID of the process that invoked this shell. |
| 1392 |  |  | In a subshell (see Section 2.12 (on page 61)), PPID shall be set to the same |
| 1393 |  |  | value as that of the parent of the current shell. For example, echo \$PPID and |
| 1394 |  |  | (echo \$PPID) would produce the same value. This volume of |
| 1395 |  |  | IEEE Std 1003.1-200x specifies the effects of the variable only for systems |
| 1396 |  |  | supporting the User Portability Utilities option. |
| 1397 |  | PS1 | Each time an interactive shell is ready to read a command, the value of this |
| 1398 |  |  | variable shall be subjected to parameter expansion and written to standard |
| 1399 |  |  | error. The default value shall be "\$ ". For users who have specific additional |
| 1400 |  |  | implementation-defined privileges, the default may be another, |
| 1401 |  |  | implementation-defined value. The shell shall replace each instance of the |
| 1402 |  |  | character ' !' in PS1 with the history file number of the next command to be |
| 1403 |  |  | typed. Escaping the '!' with another '!' (that is, " ! ! ") shall place the literal |
| 1404 |  |  | character '!' in the prompt. This volume of IEEE Std 1003.1-200x specifies |
| 1405 |  |  | the effects of the variable only for systems supporting the User Portability |
| 1406 |  |  | Utilities option. |
| 1407 |  | PS2 | Each time the user enters a <newline> prior to completing a command line in an interactive shell, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is "> ". This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option. |
| 1408 |  |  |  |
| 1409 |  |  |  |
| 1410 |  |  |  |
| 1411 |  |  |  |
| 1412 |  | PS4 | When an execution trace (set $-\mathbf{x}$ ) is being performed in an interactive shell, before each line in the execution trace, the value of this variable shall be subjected to parameter expansion and written to standard error. The default value is "+ ". This volume of IEEE Std 1003.1-200x specifies the effects of the variable only for systems supporting the User Portability Utilities option. |
| 1413 |  |  |  |
| 1414 |  |  |  |
| 1415 |  |  |  |
| 1416 |  |  |  |
| 1417 |  | PWD | Set by the shell to be an absolute pathname of the current working directory, |
| 1418 |  |  | ontaining no components of type symbolic link, no components that are dot, |
| 1419 |  |  | d no components that are dot-dot when the shell is initialized. If an |
| 1420 |  |  | application sets or unsets the value of PWD, the behaviors of the $c d$ and pwd |
| 1421 |  |  | utilities are unspecified. |

### 2.6 Word Expansions

This section describes the various expansions that are performed on words. Not all expansions are performed on every word, as explained in the following sections.
Tilde expansions, parameter expansions, command substitutions, arithmetic expansions, and quote removals that occur within a single word expand to a single field. It is only field splitting or pathname expansion that can create multiple fields from a single word. The single exception to this rule is the expansion of the special parameter ' @' within double-quotes, as described in Section 2.5.2 (on page 34).
The order of word expansion shall be as follows:

1. Tilde expansion (see Section 2.6.1 (on page 37)), parameter expansion (see Section 2.6.2 (on page 38)), command substitution (see Section 2.6 .3 (on page 40)), and arithmetic expansion (see Section 2.6 .4 (on page 41)) shall be performed, beginning to end. See item 5 in Section 2.3 (on page 31).
2. Field splitting (see Section 2.6 .5 (on page 42)) shall be performed on the portions of the fields generated by step 1 , unless IFS is null.
3. Pathname expansion (see Section 2.6 .6 (on page 43)) shall be performed, unless set $-\mathbf{f}$ is in effect.
4. Quote removal (see Section 2.6.7 (on page 43)) shall always be performed last.

The expansions described in this section shall occur in the same shell environment as that in which the command is executed.
If the complete expansion appropriate for a word results in an empty field, that empty field shall be deleted from the list of fields that form the completely expanded command, unless the original word contained single-quote or double-quote characters.

The ' $\$$ ' character is used to introduce parameter expansion, command substitution, or arithmetic evaluation. If an unquoted ' $\$$ ' is followed by a character that is either not numeric, the name of one of the special parameters (see Section 2.5.2 (on page 34)), a valid first character of a variable name, a left curly brace ( ${ }^{\prime}\{\prime$ ) or a left parenthesis, the result is unspecified.

### 2.6.1 Tilde Expansion

A "tilde-prefix" consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the characters in the word if there is no slash. In an assignment (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.21, Variable Assignment), multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), following any unquoted colon, or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the characters in the tildeprefix following the tilde are treated as a possible login name from the user database. A portable login name cannot contain characters outside the set given in the description of the LOGNAME environment variable in the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.3, Other Environment Variables. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix is replaced by the value of the variable HOME. If HOME is unset, the results are unspecified. Otherwise, the tilde-prefix shall be replaced by a pathname of the initial working directory associated with the login name obtained using the getpwnam() function as defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the system does not recognize the login name, the results are undefined.

### 2.6.2 Parameter Expansion

The format for parameter expansion is as follows:
\$ \{expression\}
where expression consists of all characters until the matching '\}'. Any ' \}' escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions, and variable expansions, shall not be examined in determining the matching ' $\}^{\prime}$.
The simplest form for parameter expansion is:

```
$ {parameter}
```

The value, if any, of parameter shall be substituted.
The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when parameter is followed by a character that could be interpreted as part of the name. The matching closing brace shall be determined by counting brace levels, skipping over enclosed quoted strings, and command substitutions.
If the parameter name or symbol is not enclosed in braces, the expansion shall use the longest valid name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name), whether or not the symbol represented by that name exists.
If a parameter expansion occurs inside double-quotes:

- Pathname expansion shall not be performed on the results of the expansion.
- Field splitting shall not be performed on the results of the expansion, with the exception of ' @'; see Section 2.5.2 (on page 34).
In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of word is needed (based on the state of parameter, as described below), word shall be subjected to tilde expansion, parameter expansion, command substitution, and arithmetic expansion. If word is not needed, it shall not be expanded. The ' $\}$ ' character that delimits the following parameter expansion modifications shall be determined as described previously in this section and in Section 2.2.3 (on page 30 ). (For example, $\$\{\mathbf{f o o}-\mathbf{b a r}\} \mathbf{x y z}\}$ would result in the expansion of foo followed by the string $\mathbf{x y z}\}$ if foo is set, else the string "barxyz\}").
\$\{parameter:-word\} Use Default Values. If parameter is unset or null, the expansion of word shall be substituted; otherwise, the value of parameter shall be substituted.
\$\{parameter:=word\} Assign Default Values. If parameter is unset or null, the expansion of word shall be assigned to parameter. In all cases, the final value of parameter shall be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.
\$\{parameter:?[word]\} Indicate Error if Null or Unset. If parameter is unset or null, the expansion of word (or a message indicating it is unset if word is omitted) shall be written to standard error and the shell exits with a non-zero exit status. Otherwise, the value of parameter shall be substituted. An interactive shell need not exit.
\$\{parameter:+word\} Use Alternative Value. If parameter is unset or null, null shall be substituted; otherwise, the expansion of word shall be substituted.
In the parameter expansions shown previously, use of the colon in the format shall result in a test for a parameter that is unset or null; omission of the colon shall result in a test for a

| 1511 1512 |  | parameter Set and Not Null | parameter Set But Null | parameter <br> Unset |
| :---: | :---: | :---: | :---: | :---: |
| 1513 | \$\{parameter:-word\} | substitute parameter | substitute word | substitute word |
| 1514 | \$\{parameter-word\} | substitute parameter | substitute null | substitute word |
| 1515 | \$\{parameter:=word\} | substitute parameter | assign word | assign word |
| 1516 | \$\{parameter=word\} | substitute parameter | substitute null | assign word |
| 1517 | \$\{parameter:?word\} | substitute parameter | error, exit | error, exit |
| 1518 | \$ \{parameter?word\} | substitute parameter | substitute null | error, exit |
| 1519 | \$\{parameter:+word\} | substitute word | substitute null | substitute null |
| 1520 | \$\{parameter + word\} | substitute word | substitute word | substitute null |

In all cases shown with "substitute", the expression is replaced with the value shown. In all cases shown with "assign", parameter is assigned that value, which also replaces the expression.
\$\{\#parameter\} String Length. The length in characters of the value of parameter shall be substituted. If parameter is ${ }^{\prime * \prime}$ or ${ }^{\prime} @^{\prime}$, the result of the expansion is unspecified.
The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see Section 2.13 (on page 62)), rather than regular expression notation, shall be used to evaluate the patterns. If parameter is $\boldsymbol{\prime}^{\prime *}$ or ${ }^{\prime} @^{\prime}$, the result of the expansion is unspecified. Enclosing the full parameter expansion string in double-quotes shall not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces shall have this effect.
\$\{parameter\%word\} Remove Smallest Suffix Pattern. The word shall be expanded to produce a pattern. The parameter expansion shall then result in parameter, with the smallest portion of the suffix matched by the pattern deleted.
$\$\{$ parameter \%\%word\} Remove Largest Suffix Pattern. The word shall be expanded to produce a pattern. The parameter expansion shall then result in parameter, with the largest portion of the suffix matched by the pattern deleted.
\$\{parameter\#word\} Remove Smallest Prefix Pattern. The word shall be expanded to produce a pattern. The parameter expansion shall then result in parameter, with the smallest portion of the prefix matched by the pattern deleted.
\$\{parameter\#\#word\} Remove Largest Prefix Pattern. The word shall be expanded to produce a pattern. The parameter expansion shall then result in parameter, with the largest portion of the prefix matched by the pattern deleted.

## Examples

\$\{parameter:-word\}
In this example, $l s$ is executed only if $x$ is null or unset. (The $\$(l s)$ command substitution notation is explained in Section 2.6 .3 (on page 40).)
\$\{x:-\$(ls)\}
\$\{parameter:=word\}
unset X
echo $\$\{\mathrm{X}:=\mathrm{abc}\}$
abc

```
${parameter:?word}
    unset posix
    echo ${posix:?}
    sh: posix: parameter null or not set
```

\$\{parameter:+word\}
set a b c
echo \$\{3:+posix\}
posix
\$\{\#parameter\}
HOME=/usr/posix
echo \$\{\#HOME \}
10
\$\{parameter\%word\}
$\mathrm{x}=\mathrm{file}$.c
echo $\$\{x \% . c\} .0$
file. 0
\$\{parameter\%\%word\}
$\mathrm{x}=\mathrm{posix} / \mathrm{src} /$ std
echo $\$\{x \% \% / *\}$
posix
\$\{parameter\#word\}
$\mathrm{x}=$ \$HOME $/ \mathrm{src} / \mathrm{cmd}$
echo \$\{x\#\$HOME \}
/src/cmd
\$\{parameter\#\#word\}
$\mathrm{x}=/$ one/two/three
echo $\$\{x \# \# * /\}$
three

The double-quoting of patterns is different depending on where the double-quotes are placed:
" $\$\{x \# *\}$ " The asterisk is a pattern character.
$\$\{x \# " * "\} \quad$ The literal asterisk is quoted and not special.

### 2.6.3 Command Substitution

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution shall occur when the command is enclosed as follows:
\$ (command)
or (backquoted version):
'command'
The shell shall expand the command substitution by executing command in a subshell environment (see Section 2.12 (on page 61)) and replacing the command substitution (the text of command plus the enclosing "\$()" or backquotes) with the standard output of the command, removing sequences of one or more <newline>s at the end of the substitution. Embedded <newline>s before the end of the output shall not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of IFS and quoting
that is in effect.
Within the backquoted style of command substitution, backslash shall retain its literal meaning, except when followed by: '\$', ' ', or ' $\backslash$ ' (dollar sign, backquote, backslash). The search for the matching backquote shall be satisfied by the first unquoted non-escaped backquote; during this search, if a non-escaped backquote is encountered within a shell comment, a heredocument, an embedded command substitution of the \$(command) form, or a quoted string, undefined results occur. A single-quoted or double-quoted string that begins, but does not end, within the " '. . . '" sequence produces undefined results.
With the $\$$ (command) form, all characters following the open parenthesis to the matching closing parenthesis constitute the command. Any valid shell script can be used for command, except a script consisting solely of redirections which produces unspecified results.
The results of command substitution shall not be processed for further tilde expansion, parameter expansion, command substitution, or arithmetic expansion. If a command substitution occurs inside double-quotes, field splitting and pathname expansion shall not be performed on the results of the substitution.
Command substitution can be nested. To specify nesting within the backquoted version, the application shall precede the inner backquotes with backslashes, for example:
\'command \'
If the command substitution consists of a single subshell, such as:
\$( (command) )
a conforming application shall separate the "\$(" and ' (' into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.

### 2.6.4 Arithmetic Expansion

Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion shall be as follows:
\$((expression))
The expression shall be treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell shall expand all tokens in the expression for parameter expansion, command substitution, and quote removal.
Next, the shell shall treat this as an arithmetic expression and substitute the value of the expression. The arithmetic expression shall be processed according to the rules given in Section 1.7.2.1 (on page 7), with the following exceptions:

- Only signed long integer arithmetic is required.
- Only the decimal-constant, octal-constant, and hexadecimal-constant constants specified in the ISO C standard, Section 6.4.4.1 are required to be recognized as constants.
- The $\operatorname{sizeof()~operator~and~the~prefix~and~postfix~"++"~and~"--"~operators~are~not~required.~}$
- Selection, iteration, and jump statements are not supported.

All changes to variables in an arithmetic expression shall be in effect after the arithmetic expansion, as in the parameter expansion " $\$\{x=$ value $\}$ ".
If the shell variable $x$ contains a value that forms a valid integer constant, then the arithmetic expansions $" \$((x)) "$ and $" \$((\$ x)) "$ shall return the same value.
As an extension, the shell may recognize arithmetic expressions beyond those listed. The shell may use a signed integer type with a rank larger than the rank of signed long. The shell may
use a real-floating type instead of signed long as long as it does not affect the results in cases where there is no overflow. If the expression is invalid, the expansion fails and the shell shall write a message to standard error indicating the failure.

## Examples

A simple example using arithmetic expansion:

```
# repeat a command 100 times
x=100
while [ $x -gt 0 ]
do
    command
    x=$(($x-1))
done
```

### 2.6.5 Field Splitting

After parameter expansion (Section 2.6 .2 (on page 38)), command substitution (Section 2.6.3 (on page 40)), and arithmetic expansion (Section 2.6 .4 (on page 41)), the shell shall scan the results of expansions and substitutions that did not occur in double-quotes for field splitting and multiple fields can result.

The shell shall treat each character of the IFS as a delimiter and use the delimiters as field terminators to split the results of parameter expansion and command substitution into fields.

1. If the value of IFS is a <space>, <tab>, and <newline>, or if it is unset, any sequence of <space>s, <tab>s, or <newline>s at the beginning or end of the input shall be ignored and any sequence of those characters within the input shall delimit a field. For example, the input:
<newline><space><tab>foo<tab><tab>bar<space>
yields two fields, foo and bar.
2. If the value of $I F S$ is null, no field splitting shall be performed.
3. Otherwise, the following rules shall be applied in sequence. The term "IFS white space" is used to mean any sequence (zero or more instances) of white space characters that are in the IFS value (for example, if IFS contains <space>/ <comma>/<tab>, any sequence of <space>s and <tab>s is considered IFS white space).
a. IFS white space shall be ignored at the beginning and end of the input.
b. Each occurrence in the input of an IFS character that is not IFS white space, along with any adjacent IFS white space, shall delimit a field, as described previously.
c. Non-zero-length IFS white space shall delimit a field.

### 2.6.6 Pathname Expansion

After field splitting, if set $-\mathbf{f}$ is not in effect, each field in the resulting command line shall be expanded using the algorithm described in Section 2.13 (on page 62), qualified by the rules in Section 2.13.3 (on page 63).

### 2.6.7 Quote Removal

The quote characters: ' $\backslash$ ', ''', and ${ }^{\prime \prime \prime}$ (backslash, single-quote, double-quote) that were present in the original word shall be removed unless they have themselves been quoted.

### 2.7 Redirection

Redirection is used to open and close files for the current shell execution environment (see Section 2.12 (on page 61)) or for any command. Redirection operators can be used with numbers representing file descriptors (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.165, File Descriptor) as described below.

The overall format used for redirection is:
[n]redir-op word
The number $n$ is an optional decimal number designating the file descriptor number; the application shall ensure it is delimited from any preceding text and immediately precede the redirection operator redir-op. If $\eta$ is quoted, the number shall not be recognized as part of the redirection expression. For example:
echo $\backslash 2>\mathrm{a}$
writes the character 2 into file $\mathbf{a}$. If any part of redir-op is quoted, no redirection expression is recognized. For example:
echo $2 \backslash>a$
writes the characters $2>a$ to standard output. The optional number, redirection operator, and word shall not appear in the arguments provided to the command to be executed (if any).
Open files are represented by decimal numbers starting with zero. The largest possible value is implementation-defined; however, all implementations shall support at least 0 to 9 , inclusive, for use by the application. These numbers are called "file descriptors". The values 0,1 , and 2 have special meaning and conventional uses and are implied by certain redirection operations; they are referred to as standard input, standard output, and standard error, respectively. Programs usually take their input from standard input, and write output on standard output. Error messages are usually written on standard error. The redirection operators can be preceded by one or more digits (with no intervening <blank>s allowed) to designate the file descriptor number.
If the redirection operator is "<<" or "<<-", the word that follows the redirection operator shall be subjected to quote removal; it is unspecified whether any of the other expansions occur. For the other redirection operators, the word that follows the redirection operator shall be subjected to tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal. Pathname expansion shall not be performed on the word by a non-interactive shell; an interactive shell may perform it, but shall do so only when the expansion would result in one word.
If more than one redirection operator is specified with a command, the order of evaluation is from beginning to end.
A failure to open or create a file shall cause a redirection to fail.

### 2.7.1 Redirecting Input

Input redirection shall cause the file whose name results from the expansion of word to be opened for reading on the designated file descriptor, or standard input if the file descriptor is not specified.
The general format for redirecting input is:

$$
\text { [ } n \text { ]<word }
$$

where the optional $n$ represents the file descriptor number. If the number is omitted, the redirection shall refer to standard input (file descriptor 0 ).

### 2.7.2 Redirecting Output

The two general formats for redirecting output are:
$[n]>$ word
$[n]>\mid$ word
where the optional $n$ represents the file descriptor number. If the number is omitted, the redirection shall refer to standard output (file descriptor 1).
Output redirection using the ' $>$ ' format shall fail if the noclobber option is set (see the description of set -C) and the file named by the expansion of word exists and is a regular file. Otherwise, redirection using the ' $>$ ' or " $>\mid$ " formats shall cause the file whose name results from the expansion of word to be created and opened for output on the designated file descriptor, or standard output if none is specified. If the file does not exist, it shall be created; otherwise, it shall be truncated to be an empty file after being opened.

### 2.7.3 Appending Redirected Output

Appended output redirection shall cause the file whose name results from the expansion of word to be opened for output on the designated file descriptor. The file is opened as if the open () function as defined in the System Interfaces volume of IEEE Std 1003.1-200x was called with the O_APPEND flag. If the file does not exist, it shall be created.
The general format for appending redirected output is as follows:

$$
\text { [ } n \text { ] >>word }
$$

where the optional $n$ represents the file descriptor number. If the number is omitted, the redirection refers to standard output (file descriptor 1).

### 2.7.4 Here-Document

The redirection operators "<<" and "<<-" both allow redirection of lines contained in a shell input file, known as a "here-document", to the input of a command.
The here-document shall be treated as a single word that begins after the next <newline> and continues until there is a line containing only the delimiter and a <newline>, with no <blank>s in between. Then the next here-document starts, if there is one. The format is as follows:

```
[n]<<word
    here-document
delimiter
```

where the optional $n$ represents the file descriptor number. If the number is omitted, the heredocument refers to standard input (file descriptor 0 ).
If any character in word is quoted, the delimiter shall be formed by performing quote removal on word, and the here-document lines shall not be expanded. Otherwise, the delimiter shall be the
word itself.
If no characters in word are quoted, all lines of the here-document shall be expanded for parameter expansion, command substitution, and arithmetic expansion. In this case, the backslash in the input behaves as the backslash inside double-quotes (see Section 2.2.3 (on page 30)). However, the double-quote character ( ${ }^{\prime \prime \prime}$ ) shall not be treated specially within a heredocument, except when the double-quote appears within "\$()", " ${ }^{\prime}$ ", or "\$\{\}".
If the redirection symbol is "<<-", all leading <tab>s shall be stripped from input lines and the line containing the trailing delimiter. If more than one "<<" or "<<-" operator is specified on a line, the here-document associated with the first operator shall be supplied first by the application and shall be read first by the shell.

## Examples

An example of a here-document follows:
cat <<eof1; cat <<eof2
Hi,
eof1
Helene.
eof2

### 2.7.5 Duplicating an Input File Descriptor

The redirection operator:
[ $n$ ]<\&word
shall duplicate one input file descriptor from another, or shall close one. If word evaluates to one or more digits, the file descriptor denoted by $n$, or standard input if $n$ is not specified, shall be made to be a copy of the file descriptor denoted by word; if the digits in word do not represent a file descriptor already open for input, a redirection error shall result; see Section 2.8.1 (on page 46). If word evaluates to $t^{\prime}$, file descriptor $n$, or standard input if $n$ is not specified, shall be closed. Attempts to close a file descriptor that is not open shall not constitute an error. If word evaluates to something else, the behavior is unspecified.

### 2.7.6 Duplicating an Output File Descriptor

The redirection operator:
[ $n$ ] >\&word
shall duplicate one output file descriptor from another, or shall close one. If word evaluates to one or more digits, the file descriptor denoted by $n$, or standard output if $n$ is not specified, shall be made to be a copy of the file descriptor denoted by word; if the digits in word do not represent a file descriptor already open for output, a redirection error shall result; see Section 2.8.1 (on page 46). If word evaluates to ' - ', file descriptor $n$, or standard output if $n$ is not specified, is closed. Attempts to close a file descriptor that is not open shall not constitute an error. If word evaluates to something else, the behavior is unspecified.

### 2.7.7 Open File Descriptors for Reading and Writing

The redirection operator:
[ $n$ ]<>word
shall cause the file whose name is the expansion of word to be opened for both reading and writing on the file descriptor denoted by $n$, or standard input if $n$ is not specified. If the file does not exist, it shall be created.

### 2.8 Exit Status and Errors

### 2.8.1 Consequences of Shell Errors

For a non-interactive shell, an error condition encountered by a special built-in (see Section 2.14 (on page 64)) or other type of utility shall cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

| Error | Special Built-In | Other Utilities |
| :--- | :--- | :--- |
| Shell language syntax error | Shall exit | Shall exit |
| Utility syntax error (option or operand error) | Shall exit | Shall not exit |
| Redirection error | Shall exit | Shall not exit |
| Variable assignment error | Shall exit | Shall not exit |
| Expansion error | Shall exit | Shall exit |
| Command not found | N/A | May exit |
| Dot script not found | Shall exit | N/A |

An expansion error is one that occurs when the shell expansions defined in Section 2.6 are carried out (for example, $\$ \$\{x!y\} "$, because '!' is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.
If any of the errors shown as "shall exit" or "(may) exit" occur in a subshell, the subshell shall (respectively may) exit with a non-zero status, but the script containing the subshell shall not exit because of the error.

In all of the cases shown in the table, an interactive shell shall write a diagnostic message to standard error without exiting.

### 2.8.2 Exit Status for Commands

Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.
If a command is not found, the exit status shall be 127. If the command name is found, but it is not an executable utility, the exit status shall be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.
If a command fails during word expansion or redirection, its exit status shall be greater than zero.
Internally, for purposes of deciding whether a command exits with a non-zero exit status, the shell shall recognize the entire status value retrieved for the command by the equivalent of the wait() function WEXITSTATUS macro (as defined in the System Interfaces volume of

IEEE Std 1003.1-200x). When reporting the exit status with the special parameter ' ?', the shell shall report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal shall be reported as greater than 128.

### 2.9 Shell Commands

This section describes the basic structure of shell commands. The following command descriptions each describe a format of the command that is only used to aid the reader in recognizing the command type, and does not formally represent the syntax. Each description discusses the semantics of the command; for a formal definition of the command language, consult Section 2.10 (on page 55).
A command is one of the following:

- Simple command (see Section 2.9.1 (on page 47))
- Pipeline (see Section 2.9.2 (on page 49))
- List compound-list (see Section 2.9.3 (on page 50))
- Compound command (see Section 2.9.4 (on page 52))
- Function definition (see Section 2.9.5 (on page 54))

Unless otherwise stated, the exit status of a command shall be that of the last simple command executed by the command. There shall be no limit on the size of any shell command other than that imposed by the underlying system (memory constraints, $\left\{A R G \_M A X\right\}$, and so on).

### 2.9.1 Simple Commands

A "simple command" is a sequence of optional variable assignments and redirections, in any sequence, optionally followed by words and redirections, terminated by a control operator.
When a given simple command is required to be executed (that is, when any conditional construct such as an AND-OR list or a case statement has not bypassed the simple command), the following expansions, assignments, and redirections shall all be performed from the beginning of the command text to the end:

1. The words that are recognized as variable assignments or redirections according to Section 2.10.2 are saved for processing in steps 3 and 4.
2. The words that are not variable assignments or redirections shall be expanded. If any fields remain following their expansion, the first field shall be considered the command name and remaining fields are the arguments for the command.
3. Redirections shall be performed as described in Section 2.7 (on page 43).
4. Each variable assignment shall be expanded for tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal prior to assigning the value.

In the preceding list, the order of steps 3 and 4 may be reversed for the processing of special built-in utilities; see Section 2.14 (on page 64).

If no command name results, variable assignments shall affect the current execution environment. Otherwise, the variable assignments shall be exported for the execution environment of the command and shall not affect the current execution environment (except for special built-ins). If any of the variable assignments attempt to assign a value to a read-only variable, a variable assignment error shall occur. See Section 2.8.1 for the consequences of these errors.

If there is no command name, any redirections shall be performed in a subshell environment; it is unspecified whether this subshell environment is the same one as that used for a command substitution within the command. (To affect the current execution environment, see the exec special built-in.) If any of the redirections performed in the current shell execution environment fail, the command shall immediately fail with an exit status greater than zero, and the shell shall write an error message indicating the failure. See Section 2.8.1 for the consequences of these failures on interactive and non-interactive shells.

If there is a command name, execution shall continue as described in Section 2.9.1.1 (on page 48). If there is no command name, but the command contained a command substitution, the command shall complete with the exit status of the last command substitution performed. Otherwise, the command shall complete with a zero exit status.

### 2.9.1.1 Command Search and Execution

If a simple command results in a command name and an optional list of arguments, the following actions shall be performed:

1. If the command name does not contain any slashes, the first successful step in the following sequence shall occur:
a. If the command name matches the name of a special built-in utility, that special built-in utility shall be invoked.
b. If the command name matches the name of a function known to this shell, the function shall be invoked as described in Section 2.9.5 (on page 54). If the implementation has provided a standard utility in the form of a function, it shall not be recognized at this point. It shall be invoked in conjunction with the path search in step 1d.
c. If the command name matches the name of a utility listed in the following table, that utility shall be invoked.

d. Otherwise, the command shall be searched for using the PATH environment variable as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables:
i. If the search is successful:
a. If the system has implemented the utility as a regular built-in or as a shell function, it shall be invoked at this point in the path search.
b. Otherwise, the shell executes the utility in a separate utility environment (see Section 2.12 (on page 61)) with actions equivalent to calling the execve() function as defined in the System Interfaces volume of IEEE Std 1003.1-200x with the path argument set to the pathname resulting from the search, $\arg 0$ set to the command name, and the remaining arguments set to the operands, if any.
If the execve() function fails due to an error equivalent to the [ENOEXEC] error defined in the System Interfaces volume of IEEE Std 1003.1-200x, the shell shall execute a command equivalent to having a shell invoked with the pathname resulting from the search as its first operand, with any remaining arguments passed to
the new shell, except that the value of "\$0" in the new shell may be set to the command name. If the executable file is not a text file, the shell may bypass this command execution. In this case, it shall write an error message, and shall return an exit status of 126 .

Once a utility has been searched for and found (either as a result of this specific search or as part of an unspecified shell start-up activity), an implementation may remember its location and need not search for the utility again unless the PATH variable has been the subject of an assignment. If the remembered location fails for a subsequent invocation, the shell shall repeat the search to find the new location for the utility, if any.
ii. If the search is unsuccessful, the command shall fail with an exit status of 127 and the shell shall write an error message.
2. If the command name contains at least one slash, the shell shall execute the utility in a separate utility environment with actions equivalent to calling the execve() function defined in the System Interfaces volume of IEEE Std 1003.1-200x with the path and arg0 arguments set to the command name, and the remaining arguments set to the operands, if any.
If the execve( ) function fails due to an error equivalent to the [ENOEXEC] error, the shell shall execute a command equivalent to having a shell invoked with the command name as its first operand, with any remaining arguments passed to the new shell. If the executable file is not a text file, the shell may bypass this command execution. In this case, it shall write an error message and shall return an exit status of 126 .

### 2.9.2 Pipelines

A pipeline is a sequence of one or more commands separated by the control operator ' $\mid$ '. The standard output of all but the last command shall be connected to the standard input of the next command.
The format for a pipeline is;
[!] command1 [ | command2 ...]
The standard output of command1 shall be connected to the standard input of command2. The standard input, standard output, or both of a command shall be considered to be assigned by the pipeline before any redirection specified by redirection operators that are part of the command (see Section 2.7 (on page 43)).
If the pipeline is not in the background (see Section 2.9.3.1 (on page 50)), the shell shall wait for the last command specified in the pipeline to complete, and may also wait for all commands to complete.

## Exit Status

If the reserved word ! does not precede the pipeline, the exit status shall be the exit status of the last command specified in the pipeline. Otherwise, the exit status shall be the logical NOT of the exit status of the last command. That is, if the last command returns zero, the exit status shall be 1 ; if the last command returns greater than zero, the exit status shall be zero.

### 2.9.3 Lists

An AND-OR list is a sequence of one or more pipelines separated by the operators " $\& \&$ " and " | | ".
A list is a sequence of one or more AND-OR lists separated by the operators ' ; ' and ' $\delta^{\prime}$ and optionally terminated by ${ }^{\prime} \boldsymbol{\prime}^{\prime}, \AA^{\prime}$, or <newline>.
The operators " $\& \&$ " and $"|\mid "$ shall have equal precedence and shall be evaluated with left associativity. For example, both of the following commands write solely bar to standard output:

```
false && echo foo || echo bar
true || echo foo && echo bar
```

A ';' or <newline> terminator shall cause the preceding AND-OR list to be executed sequentially; an ' $\&$ ' shall cause asynchronous execution of the preceding AND-OR list.
The term "compound-list" is derived from the grammar in Section 2.10 (on page 55); it is equivalent to a sequence of lists, separated by <newline>s, that can be preceded or followed by an arbitrary number of <newline>s.

## Examples

The following is an example that illustrates <newline>s in compound-lists:

### 2.9.3.1 Asynchronous Lists

If a command is terminated by the control operator ampersand ( $\left.{ }^{\prime} \delta^{\prime}\right)$, the shell shall execute the command asynchronously in a subshell. This means that the shell shall not wait for the command to finish before executing the next command.
The format for running a command in the background is:

```
command1 & [command2 & ... ]
```

The standard input for an asynchronous list, before any explicit redirections are performed, shall be considered to be assigned to a file that has the same properties as /dev/null. If it is an interactive shell, this need not happen. In all cases, explicit redirection of standard input shall override this activity.
When an element of an asynchronous list (the portion of the list ended by an ampersand, such as command1, above) is started by the shell, the process ID of the last command in the asynchronous list element shall become known in the current shell execution environment; see Section 2.12 (on
page 61). This process ID shall remain known until:

1. The command terminates and the application waits for the process ID.
2. Another asynchronous list is invoked before "\$!" (corresponding to the previous asynchronous list) is expanded in the current execution environment.

The implementation need not retain more than the $\left\{C H I L D \_M A X\right\}$ most recent entries in its list of known process IDs in the current shell execution environment.

## Exit Status

The exit status of an asynchronous list shall be zero.

### 2.9.3.2 Sequential Lists

Commands that are separated by a semicolon (' $\boldsymbol{\prime}^{\prime}$ ) shall be executed sequentially.
The format for executing commands sequentially shall be:
command1 [; command2] ...
Each command shall be expanded and executed in the order specified.

## Exit Status

The exit status of a sequential list shall be the exit status of the last command in the list.
2.9.3.3 AND Lists

The control operator " $\& \&$ " denotes an AND list. The format shall be:

```
command1 [ && command2] ...
```

First command1 shall be executed. If its exit status is zero, command2 shall be executed, and so on, until a command has a non-zero exit status or there are no more commands left to execute. The commands are expanded only if they are executed.

## Exit Status

The exit status of an AND list shall be the exit status of the last command that is executed in the list.

### 2.9.3.4 OR Lists

The control operator " $N$ " denotes an OR List. The format shall be:

```
command1 [ || command2] ...
```

First, command1 shall be executed. If its exit status is non-zero, command 2 shall be executed, and so on, until a command has a zero exit status or there are no more commands left to execute.

## Exit Status

The exit status of an OR list shall be the exit status of the last command that is executed in the list.

### 2.9.4 Compound Commands

The shell has several programming constructs that are "compound commands", which provide control flow for commands. Each of these compound commands has a reserved word or control operator at the beginning, and a corresponding terminator reserved word or operator at the end. In addition, each can be followed by redirections on the same line as the terminator. Each redirection shall apply to all the commands within the compound command that do not explicitly override that redirection.

### 2.9.4.1 Grouping Commands

The format for grouping commands is as follows:
(compound-list) Execute compound-list in a subshell environment; see Section 2.12 (on page 61). Variable assignments and built-in commands that affect the environment shall not remain in effect after the list finishes.
\{ compound-list; Execute compound-list in the current process environment. The semicolon shown here is an example of a control operator delimiting the $\}$ reserved word. Other delimiters are possible, as shown in Section 2.10 (on page 55); a <newline> is frequently used.

## Exit Status

The exit status of a grouping command shall be the exit status of compound-list.

### 2.9.4.2 The for Loop

The for loop shall execute a sequence of commands for each member in a list of items. The for loop requires that the reserved words do and done be used to delimit the sequence of commands.
The format for the for loop is as follows:

```
for name [ in [word... ]]
do
    compound-list
done
```

First, the list of words following in shall be expanded to generate a list of items. Then, the variable name shall be set to each item, in turn, and the compound-list executed each time. If no items result from the expansion, the compound-list shall not be executed. Omitting:

```
in word...
```

shall be equivalent to:
in "\$@"

## Exit Status

The exit status of a for command shall be the exit status of the last command that executes. If there are no items, the exit status shall be zero.

### 2.9.4.3 Case Conditional Construct

The conditional construct case shall execute the compound-list corresponding to the first one of several patterns (see Section 2.13 (on page 62)) that is matched by the string resulting from the tilde expansion, parameter expansion, command substitution, arithmetic expansion, and quote removal of the given word. The reserved word in shall denote the beginning of the patterns to be matched. Multiple patterns with the same compound-list shall be delimited by the '|' symbol. The control operator ' )' terminates a list of patterns corresponding to a given action. The compound-list for each list of patterns, with the possible exception of the last, shall be terminated with "; ;". The case construct terminates with the reserved word esac (case reversed).
The format for the case construct is as follows:

```
case word in
    [(]pattern1) compound-list;;
    [[(]pattern[ | pattern] ... ) compound-list;;] ...
    [[(]pattern[ | pattern] ... ) compound-list]
esac
The "; ; " is optional for the last compound-list.
```

In order from the beginning to the end of the case statement, each pattern that labels a compoundlist shall be subjected to tilde expansion, parameter expansion, command substitution, and arithmetic expansion, and the result of these expansions shall be compared against the expansion of word, according to the rules described in Section 2.13 (which also describes the effect of quoting parts of the pattern). After the first match, no more patterns shall be expanded, and the compound-list shall be executed. The order of expansion and comparison of multiple patterns that label a compound-list statement is unspecified.

## Exit Status

The exit status of case shall be zero if no patterns are matched. Otherwise, the exit status shall be the exit status of the last command executed in the compound-list.

### 2.9.4.4 The if Conditional Construct

The if command shall execute a compound-list and use its exit status to determine whether to execute another compound-list.
The format for the if construct is as follows:

```
if compound-list
then
    compound-list
[elif compound-list
then
    compound-list] ...
[else
    compound-list]
fi
```

The if compound-list shall be executed; if its exit status is zero, the then compound-list shall be executed and the command shall complete. Otherwise, each elif compound-list shall be executed, in turn, and if its exit status is zero, the then compound-list shall be executed and the command shall complete. Otherwise, the else compound-list shall be executed.

## Exit Status

The exit status of the if command shall be the exit status of the then or else compound-list that was executed, or zero, if none was executed.

### 2.9.4.5 The while Loop

The while loop shall continuously execute one compound-list as long as another compound-list has a zero exit status.
The format of the while loop is as follows:

```
while compound-list-1
do
    compound-list-2
done
```

The compound-list-1 shall be executed, and if it has a non-zero exit status, the while command shall complete. Otherwise, the compound-list-2 shall be executed, and the process shall repeat.

## Exit Status

The exit status of the while loop shall be the exit status of the last compound-list-2 executed, or zero if none was executed.
2.9.4.6 The until Loop

The until loop shall continuously execute one compound-list as long as another compound-list has a non-zero exit status.
The format of the until loop is as follows:

```
until compound-list-1
do
    compound-1ist-2
done
```

The compound-list-1 shall be executed, and if it has a zero exit status, the until command completes. Otherwise, the compound-list-2 shall be executed, and the process repeats.

## Exit Status

The exit status of the until loop shall be the exit status of the last compound-list-2 executed, or zero if none was executed.

### 2.9.5 Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a "function definition command".
The format of a function definition command is as follows:

```
fname() compound-command[io-redirect ...]
```

The function is named fname; the application shall ensure that it is a name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name). An implementation may allow other characters in a function name as an extension. The implementation shall maintain separate name spaces for functions and variables.
The argument compound-command represents a compound command, as described in Section 2.9.4 (on page 52).

When the function is declared, none of the expansions in Section 2.6 shall be performed on the text in compound-command or io-redirect; all expansions shall be performed as normal each time the function is called. Similarly, the optional io-redirect redirections and any variable assignments within compound-command shall be performed during the execution of the function itself, not the function definition. See Section 2.8.1 for the consequences of failures of these operations on interactive and non-interactive shells.

When a function is executed, it shall have the syntax-error and variable-assignment properties described for special built-in utilities in the enumerated list at the beginning of Section 2.14 (on page 64).

The compound-command shall be executed whenever the function name is specified as the name of a simple command (see Section 2.9.1.1 (on page 48)). The operands to the command temporarily shall become the positional parameters during the execution of the compoundcommand; the special parameter ' \#' also shall be changed to reflect the number of operands. The special parameter 0 shall be unchanged. When the function completes, the values of the positional parameters and the special parameter ' \#'/ shall be restored to the values they had before the function was executed. If the special built-in return is executed in the compoundcommand, the function completes and execution shall resume with the next command after the function call.

## Exit Status

The exit status of a function definition shall be zero if the function was declared successfully; otherwise, it shall be greater than zero. The exit status of a function invocation shall be the exit status of the last command executed by the function.

### 2.10 Shell Grammar

The following grammar defines the Shell Command Language. This formal syntax shall take precedence over the preceding text syntax description.

### 2.10.1 Shell Grammar Lexical Conventions

The input language to the shell must be first recognized at the character level. The resulting tokens shall be classified by their immediate context according to the following rules (applied in order). These rules shall be used to determine what a "token" is that is subject to parsing at the token level. The rules for token recognition in Section 2.3 shall apply.

1. A <newline> shall be returned as the token identifier NEWLINE.
2. If the token is an operator, the token identifier for that operator shall result.
3. If the string consists solely of digits and the delimiter character is one of ' $<{ }^{\prime}$ or $\left.{ }^{\prime}\right\rangle$ ', the token identifier IO_NUMBER shall be returned.
4. Otherwise, the token identifier TOKEN results.

Further distinction on TOKEN is context-dependent. It may be that the same TOKEN yields WORD, a NAME, an ASSIGNMENT, or one of the reserved words below, dependent upon the context. Some of the productions in the grammar below are annotated with a rule number from the following list. When a TOKEN is seen where one of those annotated productions could be used to reduce the symbol, the applicable rule shall be applied to convert the token identifier type of the TOKEN to a token identifier acceptable at that point in the grammar. The reduction shall then proceed based upon the token identifier type yielded by the rule applied. When more than one rule applies, the highest numbered rule shall apply (which in turn may refer to another rule). (Note that except in rule 7 , the presence of an ${ }^{\prime}={ }^{\prime}$ in the token has no effect.)

The WORD tokens shall have the word expansion rules applied to them immediately before the associated command is executed, not at the time the command is parsed.

### 2.10.2 Shell Grammar Rules

1. [Command Name]

When the TOKEN is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, the token WORD shall be returned. Also, if the parser is in any state where only a reserved word could be the next correct token, proceed as above.
Note: Because at this point quote marks are retained in the token, quoted strings cannot be recognized as reserved words. This rule also implies that reserved words are not recognized except in certain positions in the input, such as after a <newline> or semicolon; the grammar presumes that if the reserved word is intended, it is properly delimited by the user, and does not attempt to reflect that requirement directly. Also note that line joining is done before tokenization, as described in Section 2.2.1 (on page 30 ), so escaped <newline>s are already removed at this point.
Rule 1 is not directly referenced in the grammar, but is referred to by other rules, or applies globally.
2. [Redirection to or from filename]

The expansions specified in Section 2.7 shall occur. As specified there, exactly one field can result (or the result is unspecified), and there are additional requirements on pathname expansion.
3. [Redirection from here-document]

Quote removal shall be applied to the word to determine the delimiter that is used to find the end of the here-document that begins after the next <newline>.
4. [Case statement termination]

When the TOKEN is exactly the reserved word esac, the token identifier for esac shall result. Otherwise, the token WORD shall be returned.
5. [NAME in for]

When the TOKEN meets the requirements for a name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name), the token identifier NAME shall result. Otherwise, the token WORD shall be returned.
6. [Third word of for and case]
a. [case only]

When the TOKEN is exactly the reserved word in, the token identifier for in shall result. Otherwise, the token WORD shall be returned.
b. [for only]

When the TOKEN is exactly the reserved word in or do, the token identifier for in or do shall result, respectively. Otherwise, the token WORD shall be returned.
(For a. and b.: As indicated in the grammar, a linebreak precedes the tokens in and do. If <newline>s are present at the indicated location, it is the token after them that is treated in this fashion.)
7. [Assignment preceding command name]
a. [When the first word]

If the TOKEN does not contain the character ${ }^{\prime}={ }^{\prime}$, rule 1 is applied. Otherwise, 7 b shall be applied.
b. [Not the first word]

If the TOKEN contains the equal sign character:

- If it begins with ${ }^{\prime}={ }^{\prime}$, the token WORD shall be returned.
- If all the characters preceding ${ }^{\prime}={ }^{\prime}$ form a valid name (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.230, Name), the token ASSIGNMENT_WORD shall be returned. (Quoted characters cannot participate in forming a valid name.)
- Otherwise, it is unspecified whether it is ASSIGNMENT_WORD or WORD that is returned.
Assignment to the NAME shall occur as specified in Section 2.9.1 (on page 47).

8. [NAME in function]

When the TOKEN is exactly a reserved word, the token identifier for that reserved word shall result. Otherwise, when the TOKEN meets the requirements for a name, the token identifier NAME shall result. Otherwise, rule 7 applies.
9. [Body of function]

Word expansion and assignment shall never occur, even when required by the rules above, when this rule is being parsed. Each TOKEN that might either be expanded or have assignment applied to it shall instead be returned as a single WORD consisting only of characters that are exactly the token described in Section 2.3 (on page 31).

otoken NAME
\%token NEWLINE

;
```

### 2.11 Signals and Error Handling

When a command is in an asynchronous list, it shall inherit from the shell a signal action of ignored (SIG_IGN) for the SIGQUIT and SIGINT signals, and may inherit a signal mask in which SIGQUIT and SIGINT are blocked. Otherwise, the signal actions and signal mask inherited by the command shall be the same as those inherited by the shell from its parent unless a signal action is modified by the trap special built-in (see trap)
When a signal for which a trap has been set is received while the shell is waiting for the completion of a utility executing a foreground command, the trap associated with that signal shall not be executed until after the foreground command has completed. When the shell is waiting, by means of the wait utility, for asynchronous commands to complete, the reception of a signal for which a trap has been set shall cause the wait utility to return immediately with an exit status $>128$, immediately after which the trap associated with that signal shall be taken.
If multiple signals are pending for the shell for which there are associated trap actions, the order of execution of trap actions is unspecified.

### 2.12 Shell Execution Environment

A shell execution environment consists of the following:

- Open files inherited upon invocation of the shell, plus open files controlled by exec
- Working directory as set by cd
- File creation mask set by umask
- Current traps set by trap
- Shell parameters that are set by variable assignment (see the set special built-in) or from the System Interfaces volume of IEEE Std 1003.1-200x environment inherited by the shell when it begins (see the export special built-in)
- Shell functions; see Section 2.9.5
- Options turned on at invocation or by set
- Process IDs of the last commands in asynchronous lists known to this shell environment; see Section 2.9.3.1
- Shell aliases; see Section 2.3.1

Utilities other than the special built-ins (see Section 2.14 (on page 64)) shall be invoked in a separate environment that consists of the following. The initial value of these objects shall be the same as that for the parent shell, except as noted below.

- Open files inherited on invocation of the shell, open files controlled by the exec special built-in plus any modifications, and additions specified by any redirections to the utility
- Current working directory
- File creation mask
- If the utility is a shell script, traps caught by the shell shall be set to the default values and traps ignored by the shell shall be set to be ignored by the utility; if the utility is not a shell script, the trap actions (default or ignore) shall be mapped into the appropriate signal handling actions for the utility
- Variables with the export attribute, along with those explicitly exported for the duration of the command, shall be passed to the utility environment variables
The environment of the shell process shall not be changed by the utility unless explicitly specified by the utility description (for example, $c d$ and $u m a s k$ ).
A subshell environment shall be created as a duplicate of the shell environment, except that signal traps set by that shell environment shall be set to the default values. Changes made to the subshell environment shall not affect the shell environment. Command substitution, commands that are grouped with parentheses, and asynchronous lists shall be executed in a subshell environment. Additionally, each command of a multi-command pipeline is in a subshell environment; as an extension, however, any or all commands in a pipeline may be executed in the current environment. All other commands shall be executed in the current shell environment.

### 2.13 Pattern Matching Notation

The pattern matching notation described in this section is used to specify patterns for matching strings in the shell. Historically, pattern matching notation is related to, but slightly different from, the regular expression notation described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 9, Regular Expressions. For this reason, the description of the rules for this pattern matching notation are based on the description of regular expression notation, modified to include backslash escape processing.

### 2.13.1 Patterns Matching a Single Character

The following patterns matching a single character shall match a single character: ordinary characters, special pattern characters, and pattern bracket expressions. The pattern bracket expression also shall match a single collating element. A backslash character shall escape the following character. The escaping backslash shall be discarded.
An ordinary character is a pattern that shall match itself. It can be any character in the supported character set except for NUL, those special shell characters in Section 2.2 that require quoting, and the following three special pattern characters. Matching shall be based on the bit pattern used for encoding the character, not on the graphic representation of the character. If any character (ordinary, shell special, or pattern special) is quoted, that pattern shall match the character itself. The shell special characters always require quoting.
When unquoted and outside a bracket expression, the following three characters shall have special meaning in the specification of patterns:
? A question-mark is a pattern that shall match any character.

* An asterisk is a pattern that shall match multiple characters, as described in Section 2.13.2 (on page 63).
[ The open bracket shall introduce a pattern bracket expression.
The description of basic regular expression bracket expressions in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3.5, RE Bracket Expression shall also apply to the pattern bracket expression, except that the exclamation mark character (' ${ }^{\prime}$ ') shall replace the circumflex character ( ${ }^{\prime \prime}$ ') in its role in a "non-matching list" in the regular expression notation. A bracket expression starting with an unquoted circumflex character produces unspecified results.

When pattern matching is used where shell quote removal is not performed (such as in the argument to the find-name primary when find is being called using one of the exec functions as defined in the System Interfaces volume of IEEE Std 1003.1-200x, or in the pattern argument to the fnmatch () function), special characters can be escaped to remove their special meaning by preceding them with a backslash character. This escaping backslash is discarded. The sequence " $\backslash \backslash$ " represents one literal backslash. All of the requirements and effects of quoting on ordinary, shell special, and special pattern characters shall apply to escaping in this context.

### 2.13.2 Patterns Matching Multiple Characters

The following rules are used to construct patterns matching multiple characters from patterns matching a single character:

1. The asterisk $\left({ }^{\prime}{ }^{\prime \prime}\right)$ is a pattern that shall match any string, including the null string.
2. The concatenation of patterns matching a single character is a valid pattern that shall match the concatenation of the single characters or collating elements matched by each of the concatenated patterns.
3. The concatenation of one or more patterns matching a single character with one or more asterisks is a valid pattern. In such patterns, each asterisk shall match a string of zero or more characters, matching the greatest possible number of characters that still allows the remainder of the pattern to match the string.

### 2.13.3 Patterns Used for Filename Expansion

The rules described so far in Section 2.13.1 and Section 2.13 .2 are qualified by the following rules that apply when pattern matching notation is used for filename expansion:

1. The slash character in a pathname shall be explicitly matched by using one or more slashes in the pattern; it shall neither be matched by the asterisk or question-mark special characters nor by a bracket expression. Slashes in the pattern shall be identified before bracket expressions; thus, a slash cannot be included in a pattern bracket expression used for filename expansion. If a slash character is found following an unescaped open square bracket character before a corresponding closing square bracket is found, the open bracket shall be treated as an ordinary character. For example, the pattern "a[b/c]d" does not match such pathnames as abd or a/d. It only matches a pathname of literally $a[b / c] d$.
2. If a filename begins with a period (' .'), the period shall be explicitly matched by using a period as the first character of the pattern or immediately following a slash character. The leading period shall not be matched by:

- The asterisk or question-mark special characters
- A bracket expression containing a non-matching list, such as "[!a]", a range expression, such as "[\%-0]", or a character class expression, such as "[[:punct:]]"
It is unspecified whether an explicit period in a bracket expression matching list, such as " [ . abc] ", can match a leading period in a filename.

3. Specified patterns shall be matched against existing filenames and pathnames, as appropriate. Each component that contains a pattern character shall require read permission in the directory containing that component. Any component, except the last, that does not contain a pattern character shall require search permission. For example, given the pattern:
```
/foo/bar/x*/bam
```

search permission is needed for directories / and foo, search and read permissions are needed for directory bar, and search permission is needed for each $\mathbf{x}^{*}$ directory. If the pattern matches any existing filenames or pathnames, the pattern shall be replaced with those filenames and pathnames, sorted according to the collating sequence in effect in the current locale. If the pattern contains an invalid bracket expression or does not match any existing filenames or pathnames, the pattern string shall be left unchanged.

### 2.14 Special Built-In Utilities

The following "special built-in" utilities shall be supported in the shell command language. The output of each command, if any, shall be written to standard output, subject to the normal redirection and piping possible with all commands.
The term "built-in" implies that the shell can execute the utility directly and does not need to search for it. An implementation may choose to make any utility a built-in; however, the special built-in utilities described here differ from regular built-in utilities in two respects:

1. A syntax error in a special built-in utility may cause a shell executing that utility to abort, while a syntax error in a regular built-in utility shall not cause a shell executing that utility to abort. (See Section 2.8.1 for the consequences of errors on interactive and noninteractive shells.) If a special built-in utility encountering a syntax error does not abort the shell, its exit value shall be non-zero.
2. Variable assignments specified with special built-in utilities remain in effect after the built-in completes; this shall not be the case with a regular built-in or other utility.
The special built-in utilities in this section need not be provided in a manner accessible via the exec family of functions defined in the System Interfaces volume of IEEE Std 1003.1-200x.
Some of the special built-ins are described as conforming to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. For those that are not, the requirement in Section 1.11 that " -- " be recognized as a first argument to be discarded does not apply and a conforming application shall not use that argument.

NAME
break - exit from for, while, or until loop

## SYNOPSIS

```
    break [n]
```

## DESCRIPTION

The break utility shall exit from the smallest enclosing for, while, or until loop, if any; or from the $n$th enclosing loop if $n$ is specified. The value of $n$ is an unsigned decimal integer greater than or equal to 1 . The default shall be equivalent to $n=1$. If $n$ is greater than the number of enclosing loops, the outermost enclosing loop shall be exited. Execution shall continue with the command immediately following the loop.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.

## STDIN

Not used.

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

0 Successful completion.
$>0$ The $n$ value was not an unsigned decimal integer greater than or equal to 1 .

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

```
for i in * do
    if test -d "$i" then break fi done
```

## RATIONALE

In early proposals, consideration was given to expanding the syntax of break and continue to refer to a label associated with the appropriate loop as a preferable alternative to the $n$ method. However, this volume of IEEE Std 1003.1-200x does reserve the name space of command names ending with a colon. It is anticipated that a future implementation could take advantage of this and provide something like:

```
outofloop: for i in a b c d e
do
    for j in 0 1 2 3 4 5 6 7 % 8 9
    do
            if test -r "${i}${j}"
            then break outofloop
            fi
    done
done
```

and that this might be standardized after implementation experience is achieved.

## CHANGE HISTORY

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

NAME
colon — null utility
SYNOPSIS
: [argument...]
DESCRIPTION
This utility shall only expand command arguments. It is used when a command is needed, as in the then condition of an if command, but nothing is to be done by the command.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.
STDIN
Not used.
INPUT FILES
None.
ENVIRONMENT VARIABLES
None.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.
OUTPUT FILES
None.
EXTENDED DESCRIPTION
None.
EXIT STATUS
Zero.
CONSEQUENCES OF ERRORS
Default.

## APPLICATION USAGE

None.

## EXAMPLES

```
: \$ \(\{X=a b c\}\)
    if false
    then :
    else echo \$X
    fi
    abc
```

As with any of the special built-ins, the null utility can also have variable assignments and redirections associated with it, such as:
$x=y$ : > z
which sets variable $x$ to the value $y$ (so that it persists after the null utility completes) and creates or truncates file $\mathbf{z}$.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME continue - continue for, while, or until loop

## SYNOPSIS

continue [ $n$ ]

## DESCRIPTION

The continue utility shall return to the top of the smallest enclosing for, while, or until loop, or to the top of the $n$th enclosing loop, if $n$ is specified. This involves repeating the condition list of a while or until loop or performing the next assignment of a for loop, and re-executing the loop if appropriate.

The value of $n$ is a decimal integer greater than or equal to 1 . The default shall be equivalent to $n=1$. If $n$ is greater than the number of enclosing loops, the outermost enclosing loop shall be used.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.

## CHANGE HISTORY

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

NAME
dot - execute commands in the current environment

## SYNOPSIS

```
. file
```

## DESCRIPTION

The shell shall execute commands from the file in the current environment.
If file does not contain a slash, the shell shall use the search path specified by PATH to find the directory containing file. Unlike normal command search, however, the file searched for by the dot utility need not be executable. If no readable file is found, a non-interactive shell shall abort; an interactive shell shall write a diagnostic message to standard error, but this condition shall not be considered a syntax error.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.
STDIN
Not used.
INPUT FILES
See the DESCRIPTION.
ENVIRONMENT VARIABLES
See the DESCRIPTION.
ASYNCHRONOUS EVENTS
Default.
STDOUT
Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

Returns the value of the last command executed, or a zero exit status if no command is executed.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

cat foobar
foo=hello bar=world
. foobar
echo \$foo \$bar
hello world

## RATIONALE

Some older implementations searched the current directory for the file, even if the value of PATH disallowed it. This behavior was omitted from this volume of IEEE Std 1003.1-200x due to concerns about introducing the susceptibility to trojan horses that the user might be trying to avoid by leaving dot out of PATH.
The KornShell version of dot takes optional arguments that are set to the positional parameters. This is a valid extension that allows a dot script to behave identically to a function.

## FUTURE DIRECTIONS

## CHANGE HISTORY

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

NAME
eval - construct command by concatenating arguments

## SYNOPSIS

```
eval [argument...]
```

## DESCRIPTION

The eval utility shall construct a command by concatenating arguments together, separating each with a <space>. The constructed command shall be read and executed by the shell.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.

## STDIN

Not used.
INPUT FILES
None.
ENVIRONMENT VARIABLES
None.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.
EXTENDED DESCRIPTION
None.

## EXIT STATUS

If there are no arguments, or only null arguments, eval shall return a zero exit status; otherwise, it shall return the exit status of the command defined by the string of concatenated arguments separated by <space>s.

## CONSEQUENCES OF ERRORS

 Default.
## APPLICATION USAGE

None.

## EXAMPLES

foo=10 $\mathrm{x}=\mathrm{foo}$
$y=\prime$ ' $\$ x$
echo \$y
\$foo
eval $y=$ =' $\$$ ' $x$
echo \$y
10

## RATIONALE

None.

## Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
exec - execute commands and open, close, or copy file descriptors
SYNOPSIS

```
exec [command [argument...]]
```

## DESCRIPTION

The exec utility shall open, close, and/or copy file descriptors as specified by any redirections as part of the command.

If exec is specified without command or arguments, and any file descriptors with numbers greater than 2 are opened with associated redirection statements, it is unspecified whether those file descriptors remain open when the shell invokes another utility. Scripts concerned that child shells could misuse open file descriptors can always close them explicitly, as shown in one of the following examples.

If exec is specified with command, it shall replace the shell with command without creating a new process. If arguments are specified, they shall be arguments to command. Redirection affects the current shell execution environment.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.
STDIN
Not used.
INPUT FILES
None.
ENVIRONMENT VARIABLES
None.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.
STDERR
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

If command is specified, exec shall not return to the shell; rather, the exit status of the process shall be the exit status of the program implementing command, which overlaid the shell. If command is not found, the exit status shall be 127. If command is found, but it is not an executable utility, the exit status shall be 126. If a redirection error occurs (see Section 2.8 .1 (on page 46)), the shell shall exit with a value in the range $1-125$. Otherwise, exec shall return a zero exit status.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

None.

## EXAMPLES

Open readfile as file descriptor 3 for reading:

```
exec 3< readfile
```

Open writefile as file descriptor 4 for writing:
exec 4> writefile
Make file descriptor 5 a copy of file descriptor 0 :

```
exec 5<&0
```

Close file descriptor 3 :

```
exec 3<&-
```

Cat the file maggie by replacing the current shell with the cat utility:

```
exec cat maggie
```

## RATIONALE

Most historical implementations were not conformant in that:
foo=bar exec cmd
did not pass foo to cmd.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.14

## CHANGE HISTORY

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME exit - cause the shell to exit

SYNOPSIS

```
exit [n]
```

## DESCRIPTION

The exit utility shall cause the shell to exit with the exit status specified by the unsigned decimal integer $n$. If $n$ is specified, but its value is not between 0 and 255 inclusively, the exit status is undefined.

A trap on EXIT shall be executed before the shell terminates, except when the exit utility is invoked in that trap itself, in which case the shell shall exit immediately.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.
STDIN
Not used.
INPUT FILES
None.
ENVIRONMENT VARIABLES
None.
ASYNCHRONOUS EVENTS
Default.
STDOUT
Not used.
STDERR
The standard error shall be used only for diagnostic messages.
OUTPUT FILES
None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The exit status shall be $n$, if specified. Otherwise, the value shall be the exit value of the last command executed, or zero if no command was executed. When exit is executed in a trap action, the last command is considered to be the command that executed immediately preceding the trap action.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

Exit with a true value:
exit 0
Exit with a false value:
exit 1

## RATIONALE

As explained in other sections, certain exit status values have been reserved for special uses and should be used by applications only for those purposes:
126 A file to be executed was found, but it was not an executable utility.
127 A utility to be executed was not found.
$>128$ A command was interrupted by a signal.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.14

## CHANGE HISTORY

## Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

NAME
export — set the export attribute for variables

## SYNOPSIS

export name[=word]...
export -p

## DESCRIPTION

The shell shall give the export attribute to the variables corresponding to the specified names, which shall cause them to be in the environment of subsequently executed commands. If the name of a variable is followed by =word, then the value of that variable shall be set to word.
The export special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
When $-\mathbf{p}$ is specified, export shall write to the standard output the names and values of all exported variables, in the following format:
"export \%s=\%s\n", <name>, <value>
if name is set, and:
"export \%s\n", <name>
if name is unset.
The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same exporting results, except:

1. Read-only variables with values cannot be reset.
2. Variables that were unset at the time they were output need not be reset to the unset state if a value is assigned to the variable between the time the state was saved and the time at which the saved output is reinput to the shell.

When no arguments are given, the results are unspecified.

## OPTIONS

See the DESCRIPTION.

## OPERANDS

See the DESCRIPTION.

## STDIN

Not used.
INPUT FILES

## ENVIRONMENT VARIABLES

None.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

See the DESCRIPTION.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.
EXTENDED DESCRIPTION
None.

## EXIT STATUS

Zero.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

Export PWD and HOME variables:

```
export PWD HOME
```

Set and export the PATH variable:

```
export PATH=/local/bin:$PATH
```

Save and restore all exported variables:

```
export -p > temp-file
unset a lot of variables
... processing
. temp-file
```

## RATIONALE

Some historical shells use the no-argument case as the functional equivalent of what is required here with -p. This feature was left unspecified because it is not historical practice in all shells, and some scripts may rely on the now-unspecified results on their implementations. Attempts to specify the $-\mathbf{p}$ output as the default case were unsuccessful in achieving consensus. The $-\mathbf{p}$ option was added to allow portable access to the values that can be saved and then later restored using; for example, a dot script.

## FUTURE DIRECTIONS

None.
SEE ALSO
Section 2.14

## CHANGE HISTORY

Issue 6
IEEE PASC Interpretation 1003.2 \#203 is applied, clarifying the format when a variable is unset.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/6 is applied, adding the following text to the end of the first paragraph of the DESCRIPTION: "If the name of a variable is followed by $=$ word, then the value of that variable shall be set to word.". The reason for this change is that the SYNOPSIS for export includes:
export name[=word]...
but the meaning of the optional "=word" is never explained in the text.

NAME
readonly - set the readonly attribute for variables

## SYNOPSIS

$$
\begin{aligned}
& \text { readonly name [=word] . . } \\
& \text { readonly }-\mathrm{p}
\end{aligned}
$$

## DESCRIPTION

The variables whose names are specified shall be given the readonly attribute. The values of variables with the readonly attribute cannot be changed by subsequent assignment, nor can those variables be unset by the unset utility. If the name of a variable is followed by =word, then the value of that variable shall be set to word.

The readonly special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

When $-\mathbf{p}$ is specified, readonly writes to the standard output the names and values of all readonly variables, in the following format:

```
"readonly %s=%s\n", <name>, <value>
```

if name is set, and
"readonly \%s n ", <name>
if name is unset.
The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same value and readonly attribute-setting results in a shell execution environment in which:

1. Variables with values at the time they were output do not have the readonly attribute set.
2. Variables that were unset at the time they were output do not have a value at the time at which the saved output is reinput to the shell.

When no arguments are given, the results are unspecified.

## OPTIONS

See the DESCRIPTION.

## OPERANDS

See the DESCRIPTION.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

None.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

See the DESCRIPTION.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.
EXTENDED DESCRIPTION
None.

## EXIT STATUS

Zero.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

readonly HOME PWD

## RATIONALE

Some historical shells preserve the readonly attribute across separate invocations. This volume of IEEE Std 1003.1-200x allows this behavior, but does not require it.

The $-\mathbf{p}$ option allows portable access to the values that can be saved and then later restored using, for example, a dot script. Also see the RATIONALE for export for a description of the noargument and $-\mathbf{p}$ output cases and a related example.

Read-only functions were considered, but they were omitted as not being historical practice or particularly useful. Furthermore, functions must not be read-only across invocations to preclude "spoofing" (spoofing is the term for the practice of creating a program that acts like a wellknown utility with the intent of subverting the real intent of the user) of administrative or security-relevant (or security-conscious) shell scripts.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.14

## CHANGE HISTORY

## Issue 6

IEEE PASC Interpretation 1003.2 \#203 is applied, clarifying the format when a variable is unset.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/7 is applied, adding the following text to the end of the first paragraph of the DESCRIPTION: "If the name of a variable is followed by $=$ word, then the value of that variable shall be set to word.". The reason for this change is that the SYNOPSIS for readonly includes:
readonly name[=word]...
but the meaning of the optional "=word" is never explained in the text.

NAME
return - return from a function

## SYNOPSIS

$$
\text { return [ } n \text { ] }
$$

## DESCRIPTION

The return utility shall cause the shell to stop executing the current function or dot script. If the shell is not currently executing a function or dot script, the results are unspecified.

## OPTIONS

None.

## OPERANDS

See the DESCRIPTION.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

None.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

 None.EXTENDED DESCRIPTION
None.

## EXIT STATUS

The value of the special parameter '?' shall be set to $n$, an unsigned decimal integer, or to the exit status of the last command executed if $n$ is not specified. If the value of $n$ is greater than 255, the results are undefined. When return is executed in a trap action, the last command is considered to be the command that executed immediately preceding the trap action.

## CONSEQUENCES OF ERRORS

 Default.
## APPLICATION USAGE

None.
EXAMPLES
None.

## RATIONALE

The behavior of return when not in a function or dot script differs between the System V shell and the KornShell. In the System V shell this is an error, whereas in the KornShell, the effect is the same as exit.
The results of returning a number greater than 255 are undefined because of differing practices
in the various historical implementations. Some shells AND out all but the low-order 8 bits; others allow larger values, but not of unlimited size.
See the discussion of appropriate exit status values under exit (on page 77).

## FUTURE DIRECTIONS

None.
SEE ALSO
Section 2.14

## CHANGE HISTORY

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

## NAME

set - set or unset options and positional parameters

## SYNOPSIS

```
XSI set [-abCefmnuvx] [-h] [-o option] [argument...]
xSI set [+abCefmnuvx] [+h] [+o option] [argument...]
    set -- [argument...]
    set -o
    set +o
```

## DESCRIPTION

If no options or arguments are specified, set shall write the names and values of all shell variables in the collation sequence of the current locale. Each name shall start on a separate line, using the format:

```
"\%s=\%s\n", <name>, <value>
```

The value string shall be written with appropriate quoting; see the description of shell quoting in Section 2.2 (on page 30). The output shall be suitable for reinput to the shell, setting or resetting, as far as possible, the variables that are currently set; read-only variables cannot be reset.
When options are specified, they shall set or unset attributes of the shell, as described below. When arguments are specified, they cause positional parameters to be set or unset, as described below. Setting or unsetting attributes and positional parameters are not necessarily related actions, but they can be combined in a single invocation of set.
The set special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines except that options can be specified with either a leading hyphen (meaning enable the option) or plus sign (meaning disable it) unless otherwise specified.

Implementations shall support the options in the following list in both their hyphen and plussign forms. These options can also be specified as options to sh.
-a When this option is on, the export attribute shall be set for each variable to which an assignment is performed; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.21, Variable Assignment. If the assignment precedes a utility name in a command, the export attribute shall not persist in the current execution environment after the utility completes, with the exception that preceding one of the special built-in utilities causes the export attribute to persist after the built-in has completed. If the assignment does not precede a utility name in the command, or if the assignment is a result of the operation of the getopts or read utilities, the export attribute shall persist until the variable is unset.
-b This option shall be supported if the implementation supports the User Portability Utilities option. It shall cause the shell to notify the user asynchronously of background job completions. The following message is written to standard error:

```
"[%d]%c %s%s\n", <job-number>, <current>, <status>, <job-name>
```

where the fields shall be as follows:
<current> The character ${ }^{\prime}+{ }^{\prime}$ identifies the job that would be used as a default for the $f g$ or $b g$ utilities; this job can also be specified using the job_id "\%+" or " $\% \%$ ". The character ${ }^{\prime}-$ ' identifies the job that would become the default if the current default job were to exit; this job can also be specified using the job_id " \%-". For other jobs, this field is a <space>. At most one job can be identified with ${ }^{\prime}+{ }^{\prime}$ and at most one job can be identified with ${ }^{\prime} \mathbf{- '}^{\prime}$.

If there is any suspended job, then the current job shall be a suspended job. If there are at least two suspended jobs, then the previous job also shall be a suspended job.
<job-number> A number that can be used to identify the process group to the wait, $f g, b g$, and kill utilities. Using these utilities, the job can be identified by prefixing the job number with ' $\%$ '.
<status> Unspecified.
<job-name> Unspecified.
When the shell notifies the user a job has been completed, it may remove the job's process ID from the list of those known in the current shell execution environment; see Section 2.9.3.1 (on page 50). Asynchronous notification shall not be enabled by default.
-C (Uppercase C.) Prevent existing files from being overwritten by the shell's '>' redirection operator (see Section 2.7.2 (on page 44)); the ">|" redirection operator shall override this noclobber option for an individual file.
-e When this option is on, if a simple command fails for any of the reasons listed in Section 2.8.1 or returns an exit status value $>0$, and is not part of the compound list following a while, until, or if keyword, and is not a part of an AND or OR list, and is not a pipeline preceded by the! reserved word, then the shell shall immediately exit.
-f The shell shall disable pathname expansion.
xsi $\quad-\mathbf{h}$ Locate and remember utilities invoked by functions as those functions are defined (the utilities are normally located when the function is executed).
-m This option shall be supported if the implementation supports the User Portability Utilities option. All jobs shall be run in their own process groups. Immediately before the shell issues a prompt after completion of the background job, a message reporting the exit status of the background job shall be written to standard error. If a foreground job stops, the shell shall write a message to standard error to that effect, formatted as described by the jobs utility. In addition, if a job changes status other than exiting (for example, if it stops for input or 'output or is stopped by a SIGSTOP signal), the shell shall write a similar message immediately prior to writing the next prompt. This option is enabled by default for interactive shells.
-n The shell shall read commands but does not execute them; this can be used to check for shell script syntax errors. An interactive shell may ignore this option.
-o Write the current settings of the options to standard output in an unspecified format.
+o Write the current option settings to standard output in a format that is suitable for reinput to the shell as commands that achieve the same options settings.
-o option
This option is supported if the system supports the User Portability Utilities option. It shall set various options, many of which shall be equivalent to the single option letters. The following values of option shall be supported:
allexport Equivalent to -a.
errexit Equivalent to -e.
ignoreeof Prevent an interactive shell from exiting on end-of-file. This setting prevents accidental logouts when <control>-D is entered. A user shall explicitly exit to leave the interactive shell.

| 3331 3332 |  | monitor | Equivalent to $\mathbf{- m}$. This option is supported if the system supports the User Portability Utilities option. |
| :---: | :---: | :---: | :---: |
| 3333 |  | noclobber | Equivalent to -C (uppercase C). |
| 3334 |  | noglob | Equivalent to -f. |
| 3335 |  | поехес | Equivalent to -n. |
| 3336 3337 |  | nolog | Prevent the entry of function definitions into the command history; see Command History List (on page 856). |
| 3338 |  | notify | Equivalent to -b. |
| 3339 |  | nounset | Equivalent to -u. |
| 3340 |  | verbose | Equivalent to -v. |
| 3341 3342 3343 |  | vi | Allow shell command line editing using the built-in vi editor. Enabling vi mode shall disable any other command line editing mode provided as an implementation extension. |
| 3344 |  |  | It need not be possible to set vi mode on for certain block-mode terminals. |
| 3345 |  | xtrace | Equivalent to - $\mathbf{x}$. |
| 3346 3347 | -u | The shell not set and | all write a message to standard error when it tries to expand a variable that is mmediately exit. An interactive shell shall not exit. |
| 3348 |  | The shel | all write its input to standard error as it is read. |
| 3349 3350 3351 |  | The shell command tracing off | hall write to standard error a trace for each command after it expands the and before it executes it. It is unspecified whether the command that turns traced. |
| 3352 3353 | The default for all these options shall be off (unset) unless stated otherwise in the description of the option or unless the shell was invoked with them on, see sh. |  |  |
| 3354 3355 3356 | The remaining arguments shall be assigned in order to the positional parameters. The special parameter '\#' shall be set to reflect the number of positional parameters. All positional parameters shall be unset before any new values are assigned. |  |  |
| 3357 | If the first argument is ' - ', the results are unspecified. |  |  |
| 3358 3359 3360 | The special argument "--" immediately following the set command name can be used to delimit the arguments if the first argument begins with ' + ' or ${ }^{\prime} \mathbf{- '}^{\prime}$, or to prevent inadvertent listing of all shell variables when there are no arguments. The command set -- without argument shall unset all positional) parameters and set the special parameter ' \#' to zero. |  |  |

## APPLICATION USAGE

None.

## EXAMPLES

Write out all variables and their values:
set
Set \$1, \$2, and \$3 and set "\$\# " to 3:
set c a b
Turn on the $-\mathbf{x}$ and $-\mathbf{v}$ options:
set -xv
Unset all positional parameters:
set --
Set $\$ 1$ to the value of $x$, even if it begins with ' $-{ }^{\prime}$ or ${ }^{\prime}+$ ':
set -- "\$x"
Set the positional parameters to the expansion of $x$, even if $x$ expands with a leading ${ }^{\prime} \mathbf{\prime}^{\prime}$ or $^{\prime}+{ }^{\prime}$ :
set -- \$x

## RATIONALE

The set -- form is listed specifically in the SYNOPSIS even though this usage is implied by the Utility Syntax Guidelines. The explanation of this feature removes any ambiguity about whether the set -- form might be misinterpreted as being equivalent to set without any options or arguments. The functionality of this form has been adopted from the KornShell. In System V, set -- only unsets parameters if there is at least one argument; the only way to unset all parameters is to use shift. Using the KornShell version should not affect System V scripts because there should be no reason to issue it without arguments deliberately; if it were issued as, for example:
set -- "\$@"
and there were in fact no arguments resulting from "\$@", unsetting the parameters would have no result.

The set + form in early proposals was omitted as being an unnecessary duplication of set alone and not widespread historical practice.
The noclobber option was changed to allow set $-\mathbf{C}$ as well as the set $-\mathbf{o}$ noclobber option. The single-letter version was added so that the historical "\$-" paradigm would not be broken; see Section 2.5.2 (on page 34).

The -h flag is related to command name hashing and is only required on XSI-conformant systems.

The following set flags were omitted intentionally with the following rationale:
$-\mathbf{k}$ The $-\mathbf{k}$ flag was originally added by the author of the Bourne shell to make it easier for users of pre-release versions of the shell. In early versions of the Bourne shell the construct set name=value had to be used to assign values to shell variables. The problem with $-\mathbf{k}$ is that the behavior affects parsing, virtually precluding writing any compilers. To explain the behavior of $-\mathbf{k}$, it is necessary to describe the parsing algorithm, which is implementationdefined. For example:

```
set -k; echo name=value
```

and:
set -k
echo name=value
behave differently. The interaction with functions is even more complex. What is more, the $-\mathbf{k}$ flag is never needed, since the command line could have been reordered.
-t The -t flag is hard to specify and almost never used. The only known use could be done with here-documents. Moreover, the behavior with $k s h$ and sh differs. The reference page says that it exits after reading and executing one command. What is one command? If the input is date;date, sh executes both date commands while $k s h$ does only the first.
Consideration was given to rewriting set to simplify its confusing syntax. A specific suggestion was that the unset utility should be used to unset options instead of using the non-getopt ()-able +option syntax. However, the conclusion was reached that the historical practice of using +option was satisfactory and that there was no compelling reason to modify such widespread historical practice.

The - o option was adopted from the KornShell to address user needs. In addition to its generally friendly interface, - $\mathbf{o}$ is needed to provide the vi command line editing mode, for which historical practice yields no single-letter option name. (Although it might have been possible to invent such a letter, it was recognized that other editing modes would be developed and -o provides ample name space for describing such extensions.)
Historical implementations are inconsistent in the format used for -o option status reporting. The +o format without an option-argument was added to allow portable access to the options that can be saved and then later restored using, for instance, a dot script.
Historically, sh did trace the command set $+\mathbf{x}$, but $k s h$ did not.
The ignoreeof setting prevents accidental logouts when the end-of-file character (typically <control>-D) is entered. A user shall explicitly exit to leave the interactive shell.

The set $\mathbf{- m}$ option was added to apply only to the UPE because it applies primarily to interactive use, not shell script applications.

The ability to do asynchronous notification became available in the 1988 version of the KornShell. To have it occur, the user had to issue the command:
trap "jobs -n" CLD

The C shell provides two different levels of an asynchronous notification capability. The environment variable notify is analogous to what is done in set $-\mathbf{b}$ or set $-\mathbf{o}$ notify. When set, it notifies the user immediately of background job completions. When unset, this capability is turned off.

The other notification ability comes through the built-in utility notify. The syntax is:
notify [\%job ... ]
By issuing notify with no operands, it causes the $C$ shell to notify the user asynchronously when the state of the current job changes. If given operands, notify asynchronously informs the user of changes in the states of the specified jobs.

To add asynchronous notification to the POSIX shell, neither the KornShell extensions to trap, nor the C shell notify environment variable seemed appropriate (notify is not a proper POSIX environment variable name).
The set -b option was selected as a compromise.
The notify built-in was considered to have more functionality than was required for simple asynchronous notification.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

## Issue 6

The obsolescent set command name followed by '-' has been removed.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The nolog option is added to set $-\mathbf{o}$.

IEEE PASC Interpretation 1003.2 \#167 is applied, clarifying that the options default also takes into account the description of the option.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/8 is applied, changing the square brackets in the example in RATIONALE to be in bold, which is the typeface used for optional items.

Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying the behavior if the first argument is ${ }^{\prime}-{ }^{\prime}$.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
shift — shift positional parameters
SYNOPSIS

```
shift [n]
```

## DESCRIPTION

The positional parameters shall be shifted. Positional parameter 1 shall be assigned the value of parameter $(1+n)$, parameter 2 shall be assigned the value of parameter $(2+n)$, and so on. The parameters represented by the numbers "\$\#" down to "\$\#-n+1" shall be unset, and the parameter ' \#' is updated to reflect the new number of positional parameters.

The value $n$ shall be an unsigned decimal integer less than or equal to the value of the special parameter ' \#'. If $n$ is not given, it shall be assumed to be 1 . If $n$ is 0 , the positional and special parameters are not changed.

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

NAME
times - write process times

## SYNOPSIS

```
times
```

## DESCRIPTION

The times utility shall write the accumulated user and system times for the shell and for all of its child processes, in the following POSIX locale format:

```
"%dm%fs %dm%fs\n%dm%fs %dm%fs\n", <shell user minutes>,
    <shell user seconds>, <shell system minutes>,
    <shell system seconds>, <children user minutes>,
    <children user seconds>, <children system minutes>,
    <children system seconds>
```

The four pairs of times shall correspond to the members of the <sys/times.h> tms structure (defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers) as returned by times( ): tms_utime, tms_stime, tms_cutime, and tms_cstime, respectively.

## \$ times

$0 \mathrm{m0.43s} 0 \mathrm{~m} 1.11 \mathrm{~s}$
8 m 44.18 s 1 m 43.23 s

## RATIONALE

The times special built-in from the Single UNIX Specification is now required for all conforming shells.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.14

## CHANGE HISTORY

## Issue 6

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/9 is applied, changing text in the DESCRIPTION from: "Write the accumulated user and system times for the shell and for all of its child processes ..." to: "The times utility shall write the accumulated user and system times for the shell and for all of its child processes ...".

NAME
trap - trap signals

## SYNOPSIS

```
trap [action condition...]
```

## DESCRIPTION

If action is ' - ', the shell shall reset each condition to the default value. If action is null (" "), the shell shall ignore each specified condition if it arises. Otherwise, the argument action shall be read and executed by the shell when one of the corresponding conditions arises. The action of trap shall override a previous action (either default action or one explicitly set). The value of "\$?" after the trap action completes shall be the value it had before trap was invoked.
The condition can be EXIT, 0 (equivalent to EXIT), or a signal specified using a symbolic name, without the SIG prefix, as listed in the tables of signal names in the <signal.h> header defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers; for example, HUP, INT, QUIT, TERM. Implementations may permit names with the SIG prefix or ignore case in signal names as an extension. Setting a trap for SIGKILL or SIGSTOP produces undefined results.

The environment in which the shell executes a trap on EXIT shall be identical to the environment immediately after the last command executed before the trap on EXIT was taken.

Each time trap is invoked, the action argument shall be processed in a manner equivalent to:
eval action
Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps shall remain in place for a given shell until explicitly changed with another trap command.
When a subshell is entered, traps that are not being ignored are set to the default actions. This does not imply that the trap command cannot be used within the subshell to set new traps.
The trap command with no arguments shall write to standard output a list of commands associated with each condition. The format shall be:
"trap $--\frac{\circ}{\circ} \mathrm{s} \cdot . . \backslash n ",<a c t i o n>,<c o n d i t i o n>\ldots$
The shell shall format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$ (trap)
eval "$save_traps"
```

xSI XSI-conformant systems also allow numeric signal numbers for the conditions corresponding to the following signal names:
1 SIGHUP
2 SIGINT
3 SIGQUIT
6 SIGABRT
9 SIGKILL

14 SIGALRM
15 SIGTERM

The trap special built-in shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

## OPTIONS

None.
OPERANDS
See the DESCRIPTION.

## STDIN

Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

None.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

See the DESCRIPTION.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

xSI If the trap name or number is invalid, a non-zero exit status shall be returned; otherwise, zero
xsi shall be returned. For both interactive and non-interactive shells, invalid signal names or numbers shall not be considered a syntax error and do not cause the shell to abort.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

Write out a list of all traps and actions:
trap
Set a trap so the logout utility in the directory referred to by the HOME environment variable executes when the shell terminates:
trap '\$HOME/logout' EXIT
or:
trap '\$HOME/logout' 0
Unset traps on INT, QUIT, TERM, and EXIT:
trap - INT QUIT TERM EXIT

## trap

## RATIONALE

Implementations may permit lowercase signal names as an extension. Implementations may also accept the names with the SIG prefix; no known historical shell does so. The trap and kill utilities in this volume of IEEE Std 1003.1-200x are now consistent in their omission of the SIG prefix for signal names. Some kill implementations do not allow the prefix, and kill -1 lists the signals without prefixes.

Trapping SIGKILL or SIGSTOP is syntactically accepted by some historical implementations, but it has no effect. Portable POSIX applications cannot attempt to trap these signals.

The output format is not historical practice. Since the output of historical trap commands is not portable (because numeric signal values are not portable) and had to change to become so, an opportunity was taken to format the output in a way that a shell script could use to save and then later reuse a trap if it wanted.
The KornShell uses an ERR trap that is triggered whenever set -e would cause an exit. This is allowable as an extension, but was not mandated, as other shells have not used it.

The text about the environment for the EXIT trap invalidates the behavior of some historical versions of interactive shells which, for example, close the standard input before executing a trap on 0 . For example, in some historical interactive shell sessions the following trap on 0 would always print "--":
trap 'read foo; echo "-\$foo-"' 0

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.14

## CHANGE HISTORY

Issue 6
XSI-conforming implementations provide the mapping of signal names to numbers given above (previously this had been marked obsolescent). Other implementations need not provide this optional mapping.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
unset - unset values and attributes of variables and functions

## SYNOPSIS

```
unset [-fv] name...
```

## DESCRIPTION

Each variable or function specified by name shall be unset.
If $-\mathbf{v}$ is specified, name refers to a variable name and the shell shall unset it and remove it from the environment. Read-only variables cannot be unset.
If $-\mathbf{f}$ is specified, name refers to a function and the shell shall unset the function definition.
If neither $-\mathbf{f}$ nor $-\mathbf{v}$ is specified, name refers to a variable; if a variable by that name does not exist, it is unspecified whether a function by that name, if any, shall be unset.
Unsetting a variable or function that was not previously set shall not be considered an error and does not cause the shell to abort.

The unset special built-in shall support the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
Note that:
VARIABLE=
is not equivalent to an unset of VARIABLE; in the example, VARIABLE is set to " ". Also, the variables that can be unset should not be misinterpreted to include the special parameters (see Section 2.5 .2 (on page 34)).

## OPTIONS

See the DESCRIPTION.
OPERANDS
See the DESCRIPTION.
STDIN
Not used.

## INPUT FILES

None.
ENVIRONMENT VARIABLES
None.
ASYNCHRONOUS EVENTS
Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## EXIT STATUS

0 All name operands were successfully unset.
$>0$ At least one name could not be unset.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

None.

## EXAMPLES

Unset VISUAL variable:
unset -v VISUAL
Unset the functions foo and bar:

```
unset -f foo bar
```

## RATIONALE

Consideration was given to omitting the $-\mathbf{f}$ option in favor of an unfunction utility, but the standard developers decided to retain historical practice.

The -v option was introduced because System V historically used one name space for both variables and functions. When unset is used without options, System V historically unset either a function or a variable, and there was no confusion about which one was intended. A portable POSIX application can use unset without an option to unset a variable, but not a function; the -f option must be used.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/5 is applied so that the reference page sections use terms as described in the Utility Description Defaults (Section 1.11). No change in behavior is intended.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## 1 <br> Chapter 3 <br> Batch Environment Services

OB BE This chapter describes the services and utilities that shall be implemented on all systems that claim conformance to the Batch Environment Services and Utilities option. The functionality described in this section shall be provided on implementations that support the Batch Environment Services and Utilities option (and the rest of this section is not further shaded for this option).
Note that the Batch Environment Services and Utilities option is marked obsolescent in Issue 7.

### 3.1 General Concepts

### 3.1.1 Batch Client-Server Interaction

Batch jobs are created and managed by batch servers. A batch client interacts with a batch server to access batch services on behalf of the user. In order to use batch services, a user must have access to a batch client.

A batch server is a computational entity, such as a daemon process, that provides batch services. Batch servers route, queue, modify, and execute batch jobs on behalf of batch clients.
The batch utilities described in this volume of IEEE Std 1003.1-200x (and listed in Table 3-1 (on page 101)) are clients of batch services; they allow users to perform actions on the job such as creating, modifying, and deleting batch jobs from a shell command line. Although these batch utilities may be said to accomplish certain services, they actually obtain services on behalf of a user by means of requests to batch servers.

Table 3-1 Batch Utilities

| qalter | qmove | qris | qstat |
| :--- | :--- | :--- | :--- |
| qdel | qmsg | qselect | qsub |
| qhold | qrerun | qsig |  |

Client-server interaction takes place by means of the batch requests defined in this chapter. Because direct access to batch jobs and queues is limited to batch servers, clients and servers of different implementations can interoperate, since dependencies on private structures for batch jobs and queues are limited to batch servers. Also, batch servers may be clients of other batch servers.

### 3.1.2 Batch Queues

Two types of batch queue are described: routing queues and execution queues. When a batch job is placed in a routing queue, it is a candidate for routing. A batch job is removed from routing queues under the following conditions:

- The batch job has been routed to another queue.
- The batch job has been deleted from the batch queue.
- The batch job has been aborted.

When a batch job is placed in an execution queue, it is a candidate for execution.
A batch job is removed from an execution queue under the following conditions:

- The batch job has been executed and exited.
- The batch job has been aborted.
- The batch job has been deleted from the batch queue.
- The batch job has been moved to another queue.

Access to a batch queue is limited to the batch server that manages the batch queue. Clients never access a batch queue or a batch job directly, either to read or write information; all client access to batch queues or jobs takes place through batch servers.

### 3.1.3 Batch Job Creation

When a batch server creates a batch job on behalf of a client, it shall assign a batch job identifier to the job. A batch job identifier consists of both a sequence number that is unique among the sequence numbers issued by that server and the name of the server. Since the batch server name is unique within a name space, the job identifier is likewise unique within the name space.
The batch server that creates a batch job shall return the batch server-assigned job identifier to the client that requested the job creation. If the batch server routes or moves the job to another server, it sends the job identifier with the job. Once assigned, the job identifier of a batch job shall never change.

### 3.1.4 Batch Job Tracking

Since a batch job may be moved after creation, the batch server name component of the job identifier need not indicate the location of the job. An implementation may provide a batch job tracking mechanism, in which case the user generally does not need to know the location of the job. However, an implementation need not provide a batch job tracking mechanism, in which case the user must find routed jobs by probing the possible destinations.

### 3.1.5 Batch Job Routing

To route a batch job, a batch server either moves the job to some other queue that is managed by the batch server, or requests that some other batch server accept the job.
Each routing queue has one or more queues to which it can route batch jobs. The batch server administrator creates routing queues.
A batch server may route a batch job from a routing queue to another routing queue. Batch servers shall prevent or otherwise handle cases of circular routing paths. As a deferred service, a batch server routes jobs from the routing queues that it manages. The algorithm by which a batch server selects a batch queue to which to route a batch job is implementation-defined.
A batch job need not be eligible for routing to all the batch queues fed by the routing queue from
which it is routed. A batch server that has been asked to accept the job may reject the request if the job requires resources that are unavailable to that batch server, or if the client is not authorized to access the batch server.

Batch servers may route high-priority jobs before low-priority jobs, but, on other than overloaded systems, the effect may be imperceptible to the user. If all the batch servers fed by a routing queue reject requests to accept the job for reasons that are permanent, the batch server that manages the job shall abort the job. If all or some rejections are temporary, the batch server should try to route the job again at some later point.
The reasons for rejecting a batch job are implementation-defined.
The reasons for which the routing should be retried later and the reasons for which the job should be aborted are also implementation-defined.

### 3.1.6 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the Shell_Path attribute of the job. The script shall be passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state. The primary program that is executed by a batch job is typically, though not necessarily, a shell program.
A batch server shall execute eligible jobs as a deferred service-no client request is necessary once the batch job is created and eligible. However, the attributes of a batch job, such as the job hold type, may render the job ineligible. A batch server shall scan the execution queues that it manages for jobs that are eligible for execution. The algorithm by which the batch server selects eligible jobs for execution is implementation-defined.

As part of creating the process for the batch job, the batch server shall open the standard output and standard error streams of the session.

The attributes of a batch job may indicate that the batch server executing the job shall send mail to a list of users at the time it begins execution of the job.

### 3.1.7 Batch Job Exit

When the session leader of an executing job terminates, the job exits. As part of exiting a batch job, the batch server that manages the job shall remove the job from the batch queue in which it resides. The server shall transfer output files of the job to a location described by the attributes of the job.
The attributes of a batch job may indicate that the batch server managing the job shall send mail to a list of users at the time the job exits.

### 3.1.8 Batch Job Abort

A batch server shall abort jobs for which a required deferred service cannot be performed. The attributes of a batch job may indicate that the batch server that aborts the job shall send mail to a list of users at the time it aborts the job.

### 3.1.9 Batch Authorization

Clients, such as the batch environment utilities (marked BE), access batch services by means of requests to one or more batch servers. To acquire the services of any given batch server, the user

Table 3-2 Environment Variable Summary

| Variable | Description |
| :--- | :--- |
| PBS_DPREFIX | Defines the directive prefix (see qsub) |
| PBS_ENVIRONMENT | Batch Job is batch or interactive (see Section 3.2.2.1) |
| PBS_JOBID | The job_identifier attribute of job (see Section 3.2.3.8) |
| PBS_JOBNAME | The job_name attribute of job (see Section 3.2.3.8) |
| PBS_O_HOME | Defines the HOME of the batch client (see qsub) |
| PBS_O_HOST | Defines the host name of the batch client (see qsub) |
| PBS_O_LANG | Defines the LANG of the batch client (see qsub) |
| PBS_O_LOGNAME | Defines the LOGNAME of the batch client (see qsub) |
| PBS_O_MAIL | Defines the MAIL of the batch client (see qsub) |
| PBS_O_PATH | Defines the PATH of the batch client (see qsub) |
| PBS_O_QUEUE | Defines the submit queue of the batch client (see qsub) |
| PBS_O_SHELL | Defines the SHELL of the batch client (see qsub) |
| PBS_O_TZ | Defines the TZ of the batch client (see qsub) |
| PBS_O_WORKDIR | Defines the working directory of the batch client (see qsub) |
| PBS_QUEUE | Defines the initial execution queue (see Section 3.2.2.1) |

### 3.2.1 Batch Job States

A batch job shall always be in one of the following states: QUEUED, RUNNING, HELD, WAITING, EXITING, or TRANSITING. The state of a batch job determines the types of requests that the batch server that manages the batch job can accept for the batch job. A batch server shall change the state of a batch job either in response to service requests from clients or as a result of deferred services, such as job execution or job routing.
A batch job that is in the QUEUED state resides in a queue but is still pending either execution or routing, depending on the queue type.
A batch server that queues a batch job in a routing queue shall put the batch job in the QUEUED state. A batch server that puts a batch job in an execution queue, but has not yet executed the batch job, shall put the batch job in the QUEUED state. A batch job that resides in an execution queue and is executing is defined to be in the RUNNING state. While a batch job is in the RUNNING state, a session leader is associated with the batch job.

A batch job that resides in an execution queue, but is ineligible to run because of a hold attribute, is defined to be in the HELD state.
A batch job that is not held, but must wait until a future date and time before executing, is defined to be in the WAITING state.

When the session leader associated with a running job exits, the batch job shall be placed in the EXITING state.
A batch job for which the session leader has terminated is defined to be in the EXITING state, and the batch server that manages such a batch job cannot accept job modification requests that affect the batch job. While a batch job is in the EXITING state, the batch server that manages the batch job is staging output files and notifying clients of job completion. Once a batch job has exited, it no longer exists as an object managed by a batch server.
A batch job that is being moved from a routing queue to another queue is defined to be in the TRANSITING state.
When a batch job in a routing queue has been selected to be moved to a new destination, then the batch job shall be in either the QUEUED state or the TRANSITING state, depending on the
batch server implementation.
Batch jobs with either an Execution_Time attribute value set in the future or a Hold_Types attribute of value not equal to NO_HOLD, or both, may be routed or held in the routing queue. The treatment of jobs with the Execution_Time or Hold_Types attributes in a routing queue is implementation-defined.

When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has a Hold_Types attribute value of other than NO_HOLD, then the job should be in the HELD state.
Note: The effect of a hold upon a batch job in a routing queue is implementation-defined. The implementation should use the state that matches whether the batch job can route with a hold or not.
When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:

- A Hold_Types attribute value of NO_HOLD
- An Execution_Time attribute in the past
then the batch job shall be in the QUEUED state.
When a batch job in a routing queue has not been selected to be moved to a new destination and the batch job has:
- A Hold_Types attribute value of NO_HOLD
- An Execution_Time attribute in the future
then the batch job may be in the WAITING state.
Note: The effect of a future execution time upon a batch job in a routing queue is implementationdefined. The implementation should use the state that matches whether the batch job can route with a hold or not.

Table 3-3 describes the next state of a batch job, given the current state of the batch job and the type of request. Table 3-4 describes the response of a batch server to a request, given the current state of the batch job and the type of request.

### 3.2.2 Deferred Batch Services

This section describes the deferred services performed by batch servers: job execution, job routing, job exit, job abort, and the rerunning of jobs after a restart.

### 3.2.2.1 Batch Job Execution

To execute a batch job is to create a session leader (a process) that runs the shell program indicated by the Shell_Path_List attribute of the batch job. The script is passed to the program as its standard input. An implementation may pass the script to the program by other implementation-defined means. At the time a batch job begins execution, it is defined to enter the RUNNING state.

Table 3-3 Next State Table

|  | Current State |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Request Type |  | X | Q | R | H | W |

H HELD
W WAITING
E EXITING
T TRANSITING
e Error
A batch server that has an execution queue containing jobs is said to own the queue and manage the batch jobs in that queue. A batch server that has been started shall execute the batch jobs in the execution queues owned by the batch server. The batch server shall schedule for execution those jobs in the execution queues that are in the QUEUED state. The algorithm for scheduling
execution.
Table 3-4 Results/Output Table

|  | Request Type |  |  |  |  |  | $\mathbf{X}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Legend

O OK
e Error message
The execution of a batch job by a batch server shall be controlled by job, queue, and server attributes, as defined in this section.

## Account_Name Attribute

Batch accounting is an optional feature of batch servers. If a batch server implements accounting, the statements in this section apply and the configuration variable POSIX2_PBS_ACCOUNTING shall be set to 1 .
A batch server that executes a batch job shall charge the account named in the Account_Name attribute of the batch job for resources consumed by the batch job.
If the Account_Name attribute of the batch job is absent from the batch job attribute list or is altered while the batch job is in execution, the batch server action is implementation-defined.

## Checkpoint Attribute

Batch checkpointing is an optional feature of batch servers. If a batch server implements checkpointing, the statements in this section apply and the configuration variable POSIX2_PBS_CHECKPOINT shall be set to 1 .
There are two attributes associated with the checkpointing feature: Checkpoint and Minimum_Cpu_Interval. Checkpoint is a batch job attribute, while Minimum_Cpu_Interval is a queue attribute. An implementation that does not support checkpointing shall support the Checkpoint job attribute to the extent that the batch server shall maintain and pass this attribute to other servers.

The behavior of a batch server that executes a batch job for which the value of the Checkpoint attribute is CHECKPOINT_UNSPECIFIED is implementation-defined. A batch server that executes a batch job for which the value of the Checkpoint attribute is NO_CHECKPOINT shall not checkpoint the batch job.
A batch server that executes a batch job for which the value of the Checkpoint attribute is CHECKPOINT_AT_SHUTDOWN shall checkpoint the batch job only when the batch server accepts a request to shut down during the time when the batch job is in the RUNNING state.
A batch server that executes a batch job for which the value of the Checkpoint attribute is CHECKPOINT_AT_MIN_CPU_INTERVAL shall checkpoint the batch job at the interval specified by the Minimum_Cpu_Interval attribute of the queue for which the batch job has been selected. The Minimum_Cpu_Interval attribute shall be specified in units of CPU minutes.
A batch server that executes a batch job for which the value of the Checkpoint attribute is an unsigned integer shall checkpoint the batch job at an interval that is the value of either the Checkpoint attribute, or the Minimum_Cpu_Interval attribute of the queue for which the batch job has been selected, whichever is greater. Both intervals shall be in units of CPU minutes. When the Minimum_Cpu_Interval attribute is greater than the Checkpoint attribute, the batch job shall write a warning message to the standard error stream of the batch job.

## Error_Path Attribute

The Error_Path attribute of a running job cannot be changed by a Modify Batch Job Request. When the Join_Path attribute of the batch job is set to the value FALSE and the Keep_Files attribute of the batch job does not contain the value KEEP_STD_ERROR, a batch server that executes a batch job shall perform one of the following actions:

- Set the standard error stream of the session leader of the batch job to the path described by the value of the Error_Path attribute of the batch job.
- Buffer the standard error of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the Error_Path attribute of the batch job.
Applications shall not rely on having access to the standard error of a batch job prior to the completion of the batch job.
When the Error_Path attribute does not specify a host name, then the batch server shall retain the standard error of the batch job on the host of execution.
When the Error_Path attribute does specify a host name and the Keep_Files attribute does not contain the value KEEP_STD_ERROR, then the final destination of the standard error of the batch job shall be on the host whose host name is specified.
If the path indicated by the value of the Error_Path attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.
When the batch server buffers the standard error of the batch job and the file cannot be opened for write upon completion of the batch job, then the server shall place the standard error in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the mailx utility.
If a batch server that does not buffer the standard error cannot open the standard error path of the batch job for write access, then the batch server shall abort the batch job.

## Execution_Time Attribute

A batch server shall not execute a batch job before the time represented by the value of the Execution_Time attribute of the batch job. The Execution_Time attribute is defined in seconds since the Epoch.

## Hold_Types Attribute

A batch server shall support the following hold types:
s Can be set or released by a user with at least a privilege level of batch administrator (SYSTEM).

- Can be set or released by a user with at least a privilege level of batch operator (OPERATOR).
u Can be set or released by the user with at least a privilege level of user, where the user is defined in the Job_Owner attribute (USER).
n Indicates that none of the Hold_Types attributes are set (NO_HOLD).
An implementation may define other hold types. Any additional hold types, how they are specified, their internal representation, their behavior, and how they affect the behavior of other utilities are implementation-defined.
The value of the Hold_Types attribute shall be the union of the valid hold types (' $\mathrm{s}^{\prime}, \mathrm{o}^{\prime} \mathrm{o}^{\prime}$, ' $\mathrm{u}^{\prime}$, and any implementation-defined hold types), or ' $n$ '.
A batch server shall not execute a batch job if the Hold_Types attribute of the batch job has a value other than NO_HOLD. If the Hold_Types attribute of the batch job has a value other than NO_HOLD, the batch job shall be in the HELD state.

## Job_Owner Attribute

The Job_Owner attribute consists of a pair of user name and host name values of the form:
username@hostname
A batch server that accepts a Queue Batch Job Request shall set the Job_Owner attribute to a string that is the username@hostname of the user who submitted the job.

## Join_Path Attribute

A batch server that executes a batch job for which the value of the Join_Path attribute is TRUE shall ignore the value of the Error_Path attribute and merge the standard error of the batch job with the standard output of the batch job.

## Keep_Files Attribute

A batch server that executes a batch job for which the value of the Keep_Files attribute includes the value KEEP_STD_OUTPUT shall retain the standard output of the batch job on the host where execution occurs. The standard output shall be retained in the home directory of the user under whose user ID the batch job is executed and the filename shall be the default filename for the standard output as defined under the -o option of the qsub utility. The Output_Path attribute is not modified.

A batch server that executes a batch job for which the value of the Keep_Files attribute includes the value KEEP_STD_ERROR shall retain the standard error of the batch job on the host where execution occurs. The standard error shall be retained in the home directory of the user under whose user ID the batch job is executed and the filename shall be the default filename for
standard error as defined under the -e option of the qsub utility. The Error_Path attribute is not modified.

A batch server that executes a batch job for which the value of the Keep_Files attribute includes values other than KEEP_STD_OUTPUT and KEEP_STD_ERROR shall retain these other files on the host where execution occurs. These files (with implementation-defined names) shall be retained in the home directory of the user under whose user identifier the batch job is executed.

## Mail_Points and Mail_Users Attributes

A batch server that executes a batch job for which one of the values of the Mail_Points attribute is the value MAIL_AT_BEGINNING shall send a mail message to each user account listed in the Mail_Users attribute of the batch job.
The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, and the Job_Owner attribute.

## Output_Path Attribute

The Output_Path attribute of a running job cannot be changed by a Modify Batch Job Request. When the Keep_Files attribute of the batch job does not contaín the value KEEP_STD_OUTPUT, a batch server that executes a batch job shall either:

- Set the standard output stream of the session leader of the batch job to the destination described by the value of the Output_Path attribute of the batch job.
or:
- Buffer the standard output of the session leader of the batch job until completion of the batch job, and when the batch job exits return the contents to the destination described by the value of the Output_Path attribute of the batch job.
When the Output_Path attribute does not specify a host name, then the batch server shall retain the standard output of the batch job on the host of execution.
When the Keep_Files attribute does not contain the value KEEP_STD_OUTPUT and the Output_Path attribute does specify a host name, then the final destination of the standard output of the batch job shall be on the host specified.
If the path specified in the Output_Path attribute of the batch job is a relative path, the batch server shall expand the path relative to the home directory of the user on the host to which the file is being returned.
Whether or not the batch server buffers the standard output of the batch job until completion of the batch job is implementation-defined. Applications shall not rely on having access to the standard output of a batch job prior to the completion of the batch job.
When the batch server does buffer the standard output of the batch job and the file cannot be opened for write upon completion of the batch job, then the batch server shall place the standard output in an implementation-defined location and notify the user of the location via mail. It shall be possible for the user to process this mail using the mailx utility.
If a batch server that does not buffer the standard output cannot open the standard output path of the batch job for write access, then the batch server shall abort the batch job.

## Priority Attribute

A batch server implementation may choose to preferentially execute a batch job based on the Priority attribute. The interpretation of the batch job Priority attribute by a batch server is implementation-defined. If an implementation uses the Priority attribute, it shall interpret larger values of the Priority attribute to mean the batch job shall be preferentially selected for execution.

## Rerunable Attribute

A batch job that began execution but did not complete, because the batch server either shut down or terminated abnormally, shall be requeued if the Rerunable attribute of the batch job has the value TRUE.
If a batch job, which was requeued after beginning execution but prior to completion, has a valid checkpoint file and the batch server supports checkpointing, then the batch job shall be restarted from the last valid checkpoint.
If the batch job cannot be restarted from a checkpoint, then when a batch job has a Rerunable attribute value of TRUE and was requeued after beginning execution but prior to completion, the batch server shall place the batch job into execution at the beginning of the job.

When a batch job has a Rerunable attribute value other than TRUE and was requeued after beginning execution but prior to completion, and the batch job cannot be restarted from a checkpoint, then the batch server shall abort the batch job.

## Resource_List Attribute

A batch server that executes a batch job shall establish the resource limits of the session leader of the batch job according to the values of the Resource_List attribute of the batch job. Resource limits shall be enforced by an implementation-defined method.

## Shell_Path_List Attribute

The Shell_Path_List job attribute consists of a list of pairs of pathname and host name values. The host name component can be omitted, in which case the pathname serves as the default pathname when a batch server cannot find the name of the host on which it is running in the list.
A batch server that executes a batch job shall select, from the value of the Shell_Path_List attribute of the batch job, a pathname where the shell to execute the batch job shall be found. The batch server shall select the pathname, in order of preference, according to the following methods:

- Select the pathname that contains the name of the host on which the batch server is running.
- Select the pathname for which the host name has been omitted.
- Select the pathname for the login shell of the user under which the batch job is to execute.

If the shell path value selected is an invalid pathname, the batch server shall abort the batch job.
If the value of the selected pathname from the Shell_Path_List attribute of the batch job represents a partial path, the batch server shall expand the path relative to a path that is implementation-defined.
The batch server that executes the batch job shall execute the program that was selected from the Shell_Path_List attribute of the batch job. The batch server shall pass the path to the script of the batch job as the first argument to the shell program.

## User_List Attribute

The User_List job attribute consists of a list of pairs of user name and host name values. The host name component can be omitted, in which case the user name serves as a default when a batch server cannot find the name of the host on which it is running in the list.

A batch server that executes a batch job shall select, from the value of the User_List attribute of the batch job, a user name under which to create the session leader. The server shall select the user name, in order of preference, according to the following methods:

- Select the user name of a value that contains the name of the host on which the batch server executes.
- Select the user name of a value for which the host name has been omitted.
- Select the user name from the Job_Owner attribute of the batch job.

## Variable_List Attribute

A batch server that executes a batch job shall create, in the environment of the session leader of the batch job, each environment variable listed in the Variable_List attribute of the batch job, and set the value of each such environment variable to that of the corresponding variable in the variable list.

### 3.2.2.2 Batch Job Routing

To route a batch job is to select a queue from a list and move the batch job to that queue.
A batch server that has routing queues, which have been started, shall route the jobs in the routing queues owned by the batch server. A batch server may delay the routing of a batch job. The algorithm for selecting a batch job and the queue to which it will be routed is implementation-defined.
When a routing queue has multiple possible destinations specified, then the precedence of the destinations is implementation-defined.

A batch server that routes a batch job to a queue at another server shall move the batch job into the target queue with a Queue Batch Job Request.
If the target server rejects the Queue Batch Job Request, the routing server shall retry routing the batch job or abort the batch job. A batch server that retries failed routings shall provide a means for the batch administrator to specify the number of retries and the minimum period of time between retries. The means by which an administrator specifies the number of retries and the delay between retries is implementation-defined. When the number of retries specified by the batch administrator has been exhausted, the batch server shall abort the batch job and perform the functions of Batch Job Exit; see Section 3.2.2.3 (on page 113).

### 3.2.2.3 Batch Job Exit

For each job in the EXITING state, the batch server that exited the batch job shall perform the following deferred services in the order specified:

1. If buffering standard error, move that file into the location specified by the Error_Path attribute of the batch job.
2. If buffering standard output, move that file into the location specified by the Output_Path attribute of the batch job.
3. If the Mail_Points attribute of the batch job includes MAIL_AT_EXIT, send mail to the users listed in the Mail_Users attribute of the batch job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides,
and the Job_Owner attribute.
4. Remove the batch job from the queue.

If a batch server that buffers the standard error output cannot return the standard error file to the standard error path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard error file to the batch job owner.
- Save the standard error file and mail the location and name of the file where the standard error is stored to the batch job owner.
- Save the standard error file and notify the user by other implementation-defined means.

If a batch server that buffers the standard output cannot return the standard output file to the standard output path at the time the batch job exits, the batch server shall do one of the following:

- Mail the standard output file to the batch job owner.
- Save the standard output file and mail the location and name of the file where the standard output is stored to the batch job owner.
- Save the standard output file and notify the user by other implementation-defined means.

At the conclusion of job exit processing, the batch job is no longer managed by a batch server.

### 3.2.2.4 Batch Server Restart

A batch server that has been either shutdown or terminated abnormally, and has returned to operation, is said to have "restarted".
Upon restarting, a batch server shall requeue those jobs managed by the batch server that were in the RUNNING state at the time the batch server shut down and for which the Rerunable attribute of the batch job has the value TRUE.

Queues are defined to be non-volatile. A batch server shall store the content of queues that it controls in such a way that server and system shutdowns do not erase the content of the queues.

### 3.2.2.5 Batch Job Abort

A batch server that cannot perform a deferred service for a batch job shall abort the batch job.
A batch server that aborts a batch job shall perform the following services:

- Delete the batch job from the queue in which it resides.
- If the Mail_Points attribute of the batch job includes the value MAIL_AT_ABORT, send mail to the users listed in the value of the Mail_Users attribute of the job. The mail message shall contain at least the batch job identifier, queue, and server at which the batch job currently resides, the Job_Owner attribute, and the reason for the abort.
- If the batch job was in the RUNNING state, terminate the session leader of the executing job by sending the session leader a SIGKILL, place the batch job in the EXITING state, and perform the actions of Batch Job Exit.

### 3.2.3 Requested Batch Services

This section describes the services provided by batch servers in response to requests from clients. Table $3-5$ summarizes the current set of batch service requests and for each gives its type (deferred or not) and whether it is an optional function.

Table 3-5 Batch Services Summary

| Batch Service | Deferred | Optional |
| :--- | :---: | :---: |
| Batch Job Execution | Yes | No |
| Batch Job Routing | Yes | No |
| Batch Job Exit | Yes | No |
| Batch Server Restart | Yes | No |
| Batch Job Abort | Yes | No |
| Delete Batch Job Request | No | No |
| Hold Batch Job Request | No | No |
| Batch Job Message Request | No | Yes |
| Batch Job Status Request | No | No |
| Locate Batch Job Request | No | Yes |
| Modify Batch Job Request | No | No |
| Move Batch Job Request | No | No |
| Queue Batch Job Request | No | No |
| Batch Queue Status Request | No | No |
| Release Batch Job Request | No | No |
| Rerun Batch Job Request | No | No |
| Select Batch Jobs Request | No | No |
| Server Shutdown Request | No | No |
| Server Status Request | No | No |
| Signal Batch Job Request | No | No |
| Track Batch Job Request | No | Yes |

If a request is rejected because the batch client is not authorized to perform the action, the batch server shall return the same status as when the batch job does not exist.

### 3.2.3.1 Delete Batch Job Request

A batch job is defined to have been deleted when it has been removed from the queue in which it resides and not instantiated in another queue. A client requests that the server that manages a batch job delete the batch job. Such a request is called a Delete Batch Job Request.
A batch server shall reject a Delete Batch Job Request if any of the following statements are true:

- The user of the batch client is not authorized to delete the designated job.
- The designated job is not managed by the batch server.
- The designated job is in a state inconsistent with the delete request.

A batch server may reject a Delete Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server requested to delete a batch job shall delete the batch job if the batch job exists and is not in the EXITING state.
A batch server that deletes a batch job in the RUNNING state shall send a SIGKILL signal to the
session leader of the batch job. It is implementation-defined whether additional signals are sent to the session leader of the job prior to sending the SIGKILL signal.
A batch server that deletes a batch job in the RUNNING state shall place the batch job in the EXITING state after it has killed the session leader of the batch job and shall perform the actions of Batch Job Exit.

### 3.2.3.2 Hold Batch Job Request

A batch client can request that the batch server add one or more holds to a batch job. Such a request is called a Hold Batch Job Request.
A batch server shall reject a Hold Batch Job Request if any of the following statements are true:

- The batch server does not support one or more of the requested holds to be added to the batch job.
- The user of the batch client is not authorized to add one or more of the requested holds to the batch job.
- The batch server does not manage the specified job.
- The designated job is in the EXITING state.

A batch server may reject a Hold Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a Hold Batch Job Request for a batch job in the RUNNING state shall place a hold on the batch job. The effects, if any, the hold will have on a batch job in the RUNNING state are implementation-defined.
A batch server that accepts a Hold Batch Job Request shall add each type of hold listed in the Hold Batch Job Request, that is not already present, to the value of the Hold_Types attribute of the batch job.
3.2.3.3 Batch Job Message Request

Batch Job Message Request is an optional feature of batch servers. If an implementation supports
Batch Job Message Request, the Statements in this section apply and the configuration variable
POSIX2_PBS_MESSAGE shall be set to 1 .
A batch client can request that a batch server write a message into certain output files of a batch job. Such a request is called a Batch Job Message Request.
A batch server shall reject a Batch Job Message Request if any of the following statements are true:

- The batch server does not support sending messages to jobs.
- The user of the batch elient is not authorized to post a message to the designated job.
- The designated job does not exist on the batch server.
- The designated job is not in the RUNNING state.

A batch server may reject a Batch Job Message Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a Batch Job Message Request shall write the message sent by the batch client into the files indicated by the batch client.

### 3.2.3.4 Batch Job Status Request

A batch client can request that a batch server respond with the status and attributes of a batch job. Such a request is called a Batch Job Status Request.
A batch server shall reject a Batch Job Status Request if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated job.
- The designated job is not managed by the batch server.

A batch server may reject a Batch Job Status Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a Batch Job Status Request shall return a Batch Job Status Message to the batch client.
A batch server may return other information in response to a Batch Job Status Request.

### 3.2.3.5 Locate Batch Job Request

Locate Batch Job Request is an optional feature of batch seryers. If an implementation supports Locate Batch Job Request, the statements in this section apply and the configuration variable POSIX2_PBS_LOCATE shall be set to 1 .

A batch client can ask a batch server to respond with the location of a batch job that was created by the batch server. Such a request is called a Locate Batch Job Request.
A batch server that accepts a Locate Batch Job Request shall return a Batch Job Location Message to the batch client.
A batch server may reject a Locate Batch Job Request for a batch job that was not created by that server.

A batch server may reject a Locate Batch Job Request for a batch job that is no longer managed by that server; that is, for a batch job that is not in a queue owned by that server.
A batch server may reject a Locate Batch Job Request for other implementation-defined reasons.

### 3.2.3.6 Modify Batch Job Request

Batch clients modify (alter) the attributes of a batch job by making a request to the server that manages the batch job. Such a request is called a Modify Batch Job Request.
A batch server shall reject a Modify Batch Job Request if any of the following statements are true:

- The user of the batch client is not authorized to make the requested modification to the batch job.
- The designated job is not managed by the batch server.
- The requested modification is inconsistent with the state of the batch job.
- An unrecognized resource is requested for a batch job in an execution queue.

A batch server may reject a Modify Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a Modify Batch Job Request shall modify all the specified attributes of the batch job. A batch server that rejects a Modify Batch Job Request shall modify none of the attributes of the batch job.
If the servicing by a batch server of an otherwise valid request would result in no change, then
the batch server shall indicate successful completion of the request.

### 3.2.3.7 Move Batch Job Request

A batch client can request that a batch server move a batch job to another destination. Such a request is called a Move Batch Job Request.
A batch server shall reject a Move Batch Job Request if any of the following statements are true:

- The user of the batch client is not authorized to remove the designated job from the queue in which the batch job resides.
- The user of the batch client is not authorized to move the designated job to the destination.
- The designated job is not managed by the batch server.
- The designated job is in the EXITING state.
- The destination is inaccessible.

A batch server can reject a Move Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a Move Batch fob Request shall perform the following services:

- Queue the designated job at the destination.
- Remove the designated job from the queue in which the batch job resides.

If the destination resides on another batch server, the batch server shall queue the batch job at the destination by sending a Queue Batch Job Request to the other server. If the Queue Batch Job Request fails, the batch server shall reject the Move Batch Job Request. If the Queue Batch Job Request succeeds, the batch server shall remove the batch job from its queue.
The batch server shall not modify any attributes of the batch job.
3.2.3.8 Quene Batch Job Request

A batch queue is controlled by one and only one batch server. A batch server is said to own the queues that it controls. Batch clients make requests of batch servers to have jobs queued. Such a request is called a Queue Batch Job Request.
A batch server requested to queue a batch job for which the queue is not specified shall select an implementation-defined queue for the batch job. Such a queue is called the "default queue" of the batch server. The implementation shall provide the means for a batch administrator to specify the default queue. The queue, whether specified or defaulted, is called the "target queue".
A batch server shall reject a Queue Batch Job Request if any of the following statements are true:

- The client is not authorized to create a batch job in the target queue.
- The request specifies a queue that does not exist on the batch server.
- The target queue is an execution queue and the batch server cannot satisfy a resource requirement of the batch job.
- The target queue is an execution queue and an unrecognized resource is requested.
- The target queue is an execution queue, the batch server does not support checkpointing, and the value of the Checkpoint attribute of the batch job is not NO_CHECKPOINT.
- The job requires access to a user identifier that the batch client is not authorized to access.

A batch server may reject a Queue Batch Job Request for other implementation-defined reasons.
A batch server that accepts a Queue Batch Job Request for a batch job for which the PBS_O_QUEUE value is missing from the value of the Variable_List attribute of the batch job shall add that variable to the list and set the value to the name of the target queue. Once set, no server shall change the value of PBS_O_QUEUE, even if the batch job is moved to another queue.
A batch server that accepts a Queue Batch Job Request for a batch job for which the PBS_JOBID value is missing from the value of the Variable_List attribute shall add that variable to the list and set the value to the batch job identifier assigned by the server in the format:
sequence_number.server
A batch server that accepts a Queue Batch Job Request for a batch job for which the PBS_JOBNAME value is missing from the value of the Variable_List attribute of the batch job shall add that variable to the list and set the value to the Job_Name attribute of the batch job.

### 3.2.3.9 Batch Queue Status Request

A batch client can request that a batch server respond with the status and attributes of a queue. Such a request is called a Batch Queue Status Request.

A batch server shall reject a Batch Queue Status Request if any of the following statements are true:

- The user of the batch client is not authorized to query the status of the designated queue.
- The designated queue does not exist on the batch server.

A batch server may reject a Batch Queue Status Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a Batch Queue Status Request shall return a Batch Queue Status Reply to the batch client.

### 3.2.3.10 Release Batch Job Request

A batch client can request that the server remove one or more holds from a batch job. Such a request is called a Release Batch Job Request.
A batch server shall reject a Release Batch Job Request if any of the following statements are true:

- The user of the batch client is not authorized to remove one or more of the requested holds from the batch job.
- The batch server does not manage the specified job.

A batch server may reject a Release Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a Release Batch Job Request shall remove each type of hold listed in the Release Batch Job Request, that is present, from the value of the Hold_Types attribute of the batch job.

### 3.2.3.11 Rerun Batch Job Request

To rerun a batch job is to kill the session leader of the batch job and leave the batch job eligible for re-execution. A batch client can request that a batch server rerun a batch job. Such a request is called Rerun Batch Job Request.

A batch server shall reject a Rerun Batch Job Request if any of the following statements are true:

- The user of the batch client is not authorized to rerun the designated job.
- The Rerunable attribute of the designated job has the value FALSE.
- The designated job is not in the RUNNING state.
- The batch server does not manage the designated job.

A batch server may reject a Rerun Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that rejects a Rerun Batch Job Request shall in no way modify the execution of the batch job.

A batch server that accepts a request to rerun a batch job shall perform the following services:

- Requeue the batch job in the execution queue in which it was executing.
- Send a SIGKILL signal to the process group of the session leader of the batch job.

An implementation may indicate to the batch job owner that the batch job has been rerun. Whether and how the batch job owner is notified that a batch job is rerun is implementationdefined.
A batch server that reruns a batch job may send other implementation-defined signals to the session leader of the batch job prior to sending the SIGKILL signal.

A batch server may preferentially select a rerun job for execution. Whether rerun jobs shall be selected for execution before other jobs is implementation-defined.

### 3.2.3.12 Select Batch Jobs Request

A batch client can request from a batch server a list of jobs managed by that server that match a list of selection criteria. Such a request is called a Select Batch Jobs Request. All the batch jobs managed by the batch server that receives the request are candidates for selection.
A batch server that accepts a Select Batch Jobs Request shall return a list of zero or more job identifiers that correspond to jobs that meet the selection criteria.
If the batch client is not authorized to query the status of a batch job, the batch server shall not select the batch job.

### 3.2.3.13 Server Shutdown Request

A batch server is defined to have shut down when it does not respond to requests from clients and does not perform deferred services for jobs. A batch client can request that a batch server shut down. Such a request is called a Server Shutdown Request.
A batch server shall reject a Server Shutdown Request from a client that is not authorized to shut down the batch server. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server may reject a Server Shutdown Request for other implementation-defined reasons. The reasons for which a Server Shutdown Request may be rejected are implementation-defined.

At server shutdown, a batch server shall do, in order of preference, one of the following:

- If checkpointing is implemented and the batch job is checkpointable, then checkpoint the batch job and requeue it.
- If the batch job is rerunnable, then requeue the batch job to be rerun (restarted from the beginning).
- Abort the batch job.

### 3.2.3.14 Server Status Request

A batch client can request that a batch server respond with the status and attributes of the batch server. Such a request is called a Server Status Request.
A batch server shall reject a Server Status Request if the following statement is true:

- The user of the batch client is not authorized to query the status of the designated server.

A batch server may reject a Server Status Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.

A batch server that accepts a Server Status Request shall return a Server Status Reply to the batch client.

### 3.2.3.15 Signal Batch Job Request

A batch client can request that a batch server signal the session leader of a batch job. Such a request is called a Signal Batch Job Request.
A batch server shall reject a Signal Batch Job Request if any of the following statements are true:

- The user of the batch client is not authorized to signal the batch job.
- The job is not in the RUNNING state.
- The batch server does not manage the designated job.
- The requested signal is not supported by the implementation.

A batch server may reject a Signal Batch Job Request for other implementation-defined reasons. The method used to determine whether the user of a client is authorized to perform the requested action is implementation-defined.
A batch server that accepts a request to signal a batch job shall send the signal requested by the batch client to the process group of the session leader of the batch job.

### 3.2.3.16 Track Batch Job Request

Track Batch Job Request is an optional feature of batch servers. If an implementation supports Track Batch Job Request, the statements in this section apply and the configuration variable POSIX2_PBS_TRACK shall be set to 1.
Track Batch Job Request provides a method for tracking the current location of a batch job. Clients may use the tracking information to determine the batch server that should receive a batch server request.
If Track Batch Job Request is supported by a batch server, then when the batch server queues a batch job as a result of a Queue Batch Job Request, and the batch server is not the batch server that created the batch job, the batch server shall send a Track Batch Job Request to the batch server that created the job.
If Track Batch Job Request is supported by a batch server, then the Track Batch Job Request may also
be sent to other servers as a backup to the primary server. The method by which backup servers are specified is implementation-defined.
If Track Batch Job Request is supported by a batch server that receives a Track Batch Job Request, then the batch server shall record the current location of the batch job as contained in the request.

### 3.3 Common Behavior for Batch Environment Utilities

### 3.3.1 Batch Job Identifier

A utility shall recognize job_identifiers of the format:
[sequence_number][.server_name][@server]
where:
sequence_number An integer that, when combined with server_name, provides a batch job identifier that is unique within the batch system.
server_name The name of the batch server to which the batch job was originally submitted.
server The name of the batch server that is currently managing the batch job.
If the application omits the batch server_name portion of a batch job identifier, a utility shall use the name of a default batch server.
If the application omits the batch server portion of a batch job identifier, a utility shall use:

- The batch server indicated by server_name, if present
- The name of the default batch server
- The name of the batch server that is currently managing the batch job

If only @server is specified, then the status of all jobs owned by the user on the requested server is listed.
The means by which a utility determines the default batch server is implementation-defined.
If the application presents the batch server portion of a batch job identifier to a utility, the utility shall send the request to the specified server.
A strictly conforming application shall use the syntax described for the job identifier. Whenever a batch job identifier is specified whose syntax is not recognized by an implementation, then a message for each error that occurs shall be written to standard error and the utility shall exit with an exit status greater than zero.
When a batch job identifier is supplied as an argument to a batch utility and the server_name portion of the batch job identifier is omitted, then the utility shall use the name of the default batch server.
When a batch job identifier is supplied as an argument to a batch utility and the batch server portion of the batch job identifier is omitted, then the utility shall use either:

- The name of the default batch server
or:
- The name of the batch server that is currently managing the batch job

When a batch job identifier is supplied as an argument to a batch utility and the batch server portion of the batch job identifier is specified, then the utility shall send the required Batch Server Request to the specified server.

### 3.3.2 Destination

The utility shall recognize a destination of the format:

```
[queue][@server]
```

where:
queиe $\quad$ The name of a valid execution or routing queue at the batch server denoted by @server, defined as a string of up to 15 alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set) where the first character is alphabetic.
server The name of a batch server, defined as a string of alphanumeric characters in the portable character set.
If the application omits the batch server portion of a destination, then the utility shall use either:

- The name of the default batch server
or:
- The name of the batch server that is currently managing the batch job

The means by which a utility determines the default batch server is implementation-defined.
If the application omits the queue portion of a destination, then the utility shall use the name of the default queue at the batch server chosen. The means by which a batch server determines its default queue is implementation-defined. If a destination is specified in the queue@server form, then the utility shall use the specified queue at the specified server.
A strictly conforming application shall use the syntax described for a destination. Whenever a destination is specified whose syntax is not recognized by an implementation, then a message shall be written to standard error and the utility shall exit with an exit status greater than zero.

### 3.3.3 Multiple Keyword-Value Pairs

For each option that can have multiple keyword-value pair arguments, the following rules shall apply. Examples of options that can haye list-oriented option-arguments are -u value@keyword and -1 keyword=value.

1. If a batch utility is presented with a list-oriented option-argument for which a keyword has a corresponding value that begins with a single or double quote, then the utility shall stop interpreting the input stream for delimiters until a second single or double quote, respectively, is encountered. This feature allows some flexibility for a comma (',') or equals sign $\left({ }^{\prime}=^{\prime}\right)$ to be part of the value string for a particular keyword; for example:
keywd1='val1,val2', keywd2="val3,val4"
Note: This may require the user to escape the quotes as in the following command:
foo -xkeywd1=\'val1,val2\', keywd2=\"val3, val4\"
2. If a batch server is presented with a list-oriented attribute that has a keyword that was encountered earlier in the list, then the later entry for that keyword shall replace the earlier entry.
3. If a batch server is presented with a list-oriented attribute that has a keyword without any corresponding value of the form keyword= or @keyword and the same keyword was encountered earlier in the list, then the prior entry for that keyword shall be ignored by the batch server.
4. If a batch utility is expecting a list-oriented option-argument entry of the form keyword=value, but is presented with an entry of the form keyword without any corresponding value, then the entry shall be treated as though a default value of NULL was assigned (that is, keyword=NULL) for entry parsing purposes. The utility shall include only the keyword, not the NULL value, in the associated job attribute.
5. If a batch utility is expecting a list-oriented option-argument entry of the form value@keyword, but is presented with an entry of the form value without any corresponding keyword, then the entry shall be treated as though a keyword of NULL was assigned (that is, value@NULL) for entry parsing purposes. The utility shall include only the value, not the NULL keyword, in the associated job attribute.
6. A batch server shall accept a list-oriented attribute that has multiple occurrences of the same keyword, interpreting the keywords, in order, with the last value encountered taking precedence over prior instances of the same keyword. This rule allows, but does not require, a batch utility to preprocess the attribute to remove duplicate keywords.
7. If a batch utility is presented with multiple list-oriented option-arguments on the command line or in script directives, or both, for a single option, then the utility shall concatenate, in order, any command line keyword and value pairs to the end of any directive keyword and value pairs separated by a single comma to produce a single string that is an equivalent, valid option-argument. The resulting string shall be assigned to the associated attribute of the batch job (after optionally removing duplicate entries as described in item 6).

This chapter contains the definitions of the utilities, as follows:

- Mandatory utilities that are present on every conformant system
- Optional utilities that are present only on systems supporting the associated option; see Section 1.8.1 for information on the options in this volume of IEEE Std 1003.1-200x

NAME
admin - create and administer SCCS files (DEVELOPMENT)

## SYNOPSIS

```
XSI admin -i[name] [-n] [-a login] [-d flag] [-e login] [-f flag] [-m mrlist]
    [-r rel] [-t[name] [-y[comment]] newfile
admin -n[-a login] [-d flag] [-e login] [-f flag] [-m mrlist] [-t[name]]
    [-y[comment]] newfile...
admin [-a login] [-d flag] [-m mrlist] [-r rel] [-t[name]] file...
admin -h file...
admin -z file...
```

## DESCRIPTION

The admin utility shall create new SCCS files or change parameters of existing ones. If a named file does not exist, it shall be created, and its parameters shall be initialized according to the specified options. Parameters not initialized by an option shall be assigned a default value. If a named file does exist, parameters corresponding to specified options shall be changed, and other parameters shall be left as is.
All SCCS filenames supplied by the application shall be of the form s.filename. New SCCS files shall be given read-only permission mode. Write permission in the parent directory is required to create a file. All writing done by admin shall be to a temporary $x$-file, named x.filename (see get) created with read-only mode if admin is creating a new SCCS file, or created with the same mode as that of the SCCS file if the file already exists. After successful execution of admin, the SCCS file shall be removed (if it exists), and the $x$-file shall be renamed with the name of the SCCS file. This ensures that changes are made to the SCCS file only if no errors occur.

The admin utility shall also use a transient lock file (named z.filename), which is used to prevent simultaneous updates to the SCCS file; see get.

## OPTIONS

The admin utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the $-\mathbf{i},-\mathbf{t}$, and $-\mathbf{y}$ options have optional optionarguments. These optional option-arguments shall not be presented as separate arguments. The following options are supported:
-n Create a new SCCS file. When $-\mathbf{n}$ is used without $-\mathbf{i}$, the SCCS file shall be created with control information but without any file data.
-i[name] Specify the name of a file from which the text for a new SCCS file shall be taken. The text constitutes the first delta of the file (see the $-\mathbf{r}$ option for the delta numbering scheme). If the -i option is used, but the name option-argument is omitted, the text shall be obtained by reading the standard input. If this option is omitted, the SCCS file shall be created with control information but without any file data. The $\mathbf{- i}$ option implies the $-\mathbf{n}$ option.
-r SID Specify the SID of the initial delta to be inserted. This SID shall be a trunk SID; that is, the branch and sequence numbers shall be zero or missing. The level number is optional, and defaults to 1.
$-\mathbf{t}$ [name] Specify the name of a file from which descriptive text for the SCCS file shall be taken. In the case of existing SCCS files (neither $\mathbf{- i}$ nor $\mathbf{- n}$ is specified):

- A -t option without a name option-argument shall cause the removal of descriptive text (if any) currently in the SCCS file.
- A -t option with a name option-argument shall cause the text (if any) in the named file to replace the descriptive text (if any) currently in the SCCS file.
-f flag Specify a flag, and, possibly, a value for the flag, to be placed in the SCCS file. Several -f options may be supplied on a single admin command line. Implementations shall recognize the following flags and associated values:
b Allow use of the $-\mathbf{b}$ option on a get command to create branch deltas.
cceil Specify the highest release (that is, ceiling), a number less than or equal to 9999, which may be retrieved by a get command for editing. The default value for an unspecified cflag shall be 9999.
ffloor Specify the lowest release (that is, floor), a number greater than 0 but less than 9999 , which may be retrieved by a get command for editing. The default value for an unspecified $\mathbf{f}$ flag shall be 1 .
Specify the default delta number (SID) to be used by a get command.
istr Treat the "No ID keywords" message issued by get or delta as a fatal error. In the absence of this flag, the message is only a warning. The message is issued if no SCCS identification keywords (see get) are found in the text retrieved or stored in the SCCS file. If a value is supplied, the application shall ensure that the keywords exactly match the given string; however, the string shall contain a keyword, and no embedded <newline>s.
j Allow concurrent get commands for editing on the same SID of an SCCS file. This allows multiple concurrent updates to the same version of the SCCS file.
1 list Specify a list of releases to which deltas can no longer be made (that is, get -e against one of these locked releases fails). Conforming applications shall use the following syntax to specify a list. Implementations may accept additional forms as an extension:
<list> ::= a | <range-list>
<range-1ist> ::= <range> | <range-list>, <range>
<range>: := <SID>
The character $a$ in the list shall be equivalent to specifying all releases for the named SCCS file. The non-terminal <SID> in range shall be the delta number of an existing delta associated with the SCCS file.
n Cause delta to create a null delta in each of those releases (if any) being skipped when a delta is made in a new release (for example, in making delta 5.1 after delta 2.7 , releases 3 and 4 are skipped). These null deltas shall serve as anchor points so that branch deltas may later be created from them. The absence of this flag shall cause skipped releases to be nonexistent in the SCCS file, preventing branch deltas from being created from them in the future. During the initial creation of an SCCS file, the $\mathbf{n}$ flag may be ignored; that is, if the $-\mathbf{r}$ option is used to set the release number of the initial SID to a value greater than 1, null deltas need not be created for the "skipped" releases.
qtext Substitute user-definable text for all occurrences of the \% $\mathbf{Q} \%$ keyword in the SCCS file text retrieved by get.

mmod Specify the module name of the SCCS file substituted for all occurrences of the $\% \mathbf{M} \%$ keyword in the SCCS file text retrieved by get. If the $\mathbf{m}$ flag is not specified, the value assigned shall be the name of the SCCS file with the leading ' .' removed. of the $\% \mathbf{Y} \%$ keyword in the SCCS file text retrieved by get.

Cause delta to prompt for modification request (MR) numbers as the reason for creating a delta. The optional value specifies the name of an MR number validation program. (If this flag is set when creating an SCCS file, the application shall ensure that the $\mathbf{m}$ option is also used even if its value is null.)
-d flag Remove (delete) the specified flag from an SCCS file. Several -d options may be supplied on a single admin command. See the -f option for allowable flag names. (The llist flag gives a list of releases to be unlocked. See the -f option for further description of the 1 flag and the syntax of a list.)

Specify a login name, or numerical group ID, to be added to the list of users who may make deltas (changes) to the SCCS file. A group ID shall be equivalent to specifying all login names common to that group ID. Several -a options may be used on a single admin command line. As many logins, or numerical group IDs, as desired may be on the list simultaneously. If the list of users is empty, then anyone may add deltas. If login or group ID is preceded by a ' !', the users so specified shall be denied permission to make deltas.

Specify a login name, or numerical group ID, to be erased from the list of users allowed to make deltas (changes) to the SCCS file. Specifying a group ID is equivalent to specifying all login names common to that group ID. Several -e options may be used on a single admin command line. manner identical to that of delta. In the POSIX locale, omission of the $-\mathbf{y}$ option shall result in a default comment line being inserted in the form:
"date and time created ㅇs \%s by \%s", <date>, <time>, <login>
where <date> is expressed in the format of the date utility's $\% y / \% m / \% d$ conversion specification, <time> in the format of the date utility's $\% \mathrm{~T}$ conversion specification format, and <login> is the login name of the user creating the file. reason for creating the initial delta in a manner identical to delta. The application shall ensure that the $\mathbf{v}$ flag is set and the MR numbers are validated if the $\mathbf{v}$ flag has shall be written if the $\mathbf{v}$ flag is not set or MR validation fails. with the checksum that is stored in the SCCS file. If the newly computed checksum does not match the checksum in the SCCS file, a diagnostic message shall be written.

Recompute the SCCS file checksum and store it in the first line of the SCCS file (see prevent future detection of the corruption.

## OPERANDS

The following operands shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the admin utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with s.) and unreadable files shall be silently ignored.
newfile A pathname of an SCCS file to be created.
If exactly one file or newfile operand appears, and it is ' ${ }^{\prime}$, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. NonSCCS files and unreadable files shall be silently ignored.

## STDIN

The standard input shall be a text file used only if $-\mathbf{i}$ is specified without an option-argument or if a file or newfile operand is specified as ${ }^{\prime}-^{\prime}$. If the first character of any standard input line is $<\mathrm{SOH}>$ in the POSIX locale, the results are unspecified.

## INPUT FILES

The existing SCCS files shall be text files of an unspecified format.
The application shall ensure that the file named by the $-\mathbf{i}$ option's name option-argument shall be a text file; if the first character of any line in this file is $<\mathrm{SOH}>$ in the POSIX locale, the results are unspecified. If this file contains more than 99999 lines, the number of lines recorded in the header for this file shall be 99999 for this delta.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of admin:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
$L C \_C T Y P E$ Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and the contents of the default $-\mathbf{y}$ comment.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

Any SCCS files created shall be text files of an unspecified format. During processing of a file, a locking $z$-file, as described in get (on page 476), may be created and deleted.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

It is recommended that directories containing SCCS files be writable by the owner only, and that SCCS files themselves be read-only. The mode of the directories should allow only the owner to modify SCCS files contained in the directories. The mode of the SCCS files prevents any modification at all except by SCCS commands.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.
SEE ALSO
delta, get, prs, what

## CHANGE HISTORY

First released in Issue 2.

## Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements, and to emphasize the term "shall" for implementation requirements.
The grammar is updated.
The Open Group Base Resolution bwg2001-007 is applied, adding new text to the INPUT FILES section warning that the maximum lines recorded in the file is 99999.
The Open Group Base Resolution bwg2001-009 is applied, amending the description of the -h option.

NAME
alias - define or display aliases

## SYNOPSIS

```
    alias [alias-name[=string]...]
```

## DESCRIPTION

The alias utility shall create or redefine alias definitions or write the values of existing alias definitions to standard output. An alias definition provides a string value that shall replace a command name when it is encountered; see Section 2.3.1 (on page 32).
An alias definition shall affect the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this volume of IEEE Std 1003.1-200x, the alias definition shall not affect the parent process of the current shell nor any utility environment invoked by the shell; see Section 2.12 (on page 61 ).

## OPTIONS

None.

## OPERANDS

The following operands shall be supported:
alias-name Write the alias definition to standard output.
alias-name=string
Assign the value of string to the alias alias-name.
If no operands are given, all alias definitions shall be written to standard output.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of alias:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

The format for displaying aliases (when no operands or only name operands are specified) shall be:

```
"%s=%s\n", name, value
```

The value string shall be written with appropriate quoting so that it is suitable for reinput to the shell. See the description of shell quoting in Section 2.2 (on page 30).

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ One of the name operands specified did not have an alias definition, or an error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

1. Change $l s$ to give a columnated, more annotated output:
```
alias ls="ls -CF"
```

2. Create a simple "redo" command to repeat previous entries in the command history file:
alias $r=\prime f c-s^{\prime}$
3. Use 1 K units for $d u$ :
alias du=du\-k
4. Set up nohup so that it can deal with an argument that is itself an alias name:
alias nohup="nohup "

## RATIONALE

The alias description is based on historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of IEEE Std 1003.1-200x, such as command line editing.
Since alias affects the current shell execution environment, it is generally provided as a shell regular built-in.
Historical versions of the KornShell have allowed aliases to be exported to scripts that are invoked by the same shell. This is triggered by the alias -x flag; it is allowed by this volume of IEEE Std 1003.1-200x only when an explicit extension such as $\mathbf{- x}$ is used. The standard developers considered that aliases were of use primarily to interactive users and that they should normally not affect shell scripts called by those users; functions are available to such scripts.

Historical versions of the KornShell had not written aliases in a quoted manner suitable for reentry to the shell, but this volume of IEEE Std 1003.1-200x has made this a requirement for all similar output. Therefore, consistency was chosen over this detail of historical practice.

## FUTURE DIRECTIONS

None.
SEE ALSO
Section 2.9.5

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
Issue 7
The alias utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

| 5061 | DESCRIPTION |  |
| 5062 | The ar utility is part of the Software Development Utilities option. |  |
| 5063 | The ar utility can be used to create and maintain groups of files combined into an archive. Once an archive has been created, new files can be added, and existing files in an archive can be extracted, deleted, or replaced. When an archive consists entirely of valid object files, the implementation shall format the archive so that it is usable as a library for link editing (see c99 and fort77). When some of the archived files are not valid object files, the suitability of the |  |
| 5064 |  |  |  |
| 5065 |  |  |  |
| 5066 |  |  |  |
| 5067 |  |  |  |
| 5068 | XsI | archive for library use is undefined. If an archive consists entirely of printable files, the entire archive shall be printable. |
| 5069 |  |  |
| 5070 |  | When ar creates an archive, it creates administrative information indicating whether a symbol table is present in the archive. When there is at least one object file that ar recognizes as such in the archive, an archive symbol table shall be created in the archive and maintained by ar; it is used by the link editor to search the archive. Whenever the ar utility is used to create or update the contents of such an archive, the symbol table shall be rebuilt. The -s option shall force the symbol table to be rebuilt. |
| 5071 |  |  |
| 5072 |  |  |
| 5073 |  |  |
| 5074 |  |  |
| 5075 |  |  |
| 5076 |  | All file operands can be pathnames. However, files within archives shall be named by a filename, which is the last component of the pathname used when the file was entered into the archive. The comparison of file operands to the names of files in archives shall be performed by comparing the last component of the operand to the name of the file in the archive. |
| 5077 |  |  |
| 5078 |  |  |
| 5079 |  |  |
| 5080 | XSI | It is unspecified whether multiple files in the archive may be identically named. In the case of such files, however, each file and posname operand shall match only the first file in the archive having a name that is the same as the last component of the operand. |
| 5081 |  |  |
| 5082 |  |  |

| 5083 | OPTIONS |  |  |
| :---: | :---: | :---: | :---: |
| 5084 |  | The ar utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for Guideline 9. |  |
| 5085 |  |  |  |
| 5086 |  | The following options shall be supported: |  |
| 5087 | XSI | -a | Position new files in the archive after the file named by the posname operand. |
| 5088 | XSI | -b | Position new files in the archive before the file named by the posname operand. |
| 5089 5090 |  | -c | Suppress the diagnostic message that is written to standard error by default when the archive archive is created. |
| 5091 5092 5093 | XSI | -C | Prevent extracted files from replacing like-named files in the file system. This option is useful when $-\mathbf{T}$ is also used, to prevent truncated filenames from replacing files with the same prefix. |
| 5094 |  | -d | Delete one or more files from archive. |
| 5095 5096 | XSI | -i | Position new files in the archive before the file in the archive named by the posname operand (equivalent to $-\mathbf{b}$ ). |
| 5097 5098 5099 | XSI | -m | Move the named files in the archive. The $-\mathbf{a}, \mathbf{-}$, or $-\mathbf{i}$ options with the posname operand indicate the position; otherwise, move the names files in the archive to the end of the archive. |
| 5100 5101 5102 |  | -p | Write the contents of the files in the archive named by file operands from archive to the standard output. If no file operands are specified, the contents of all files in the archive shall be written in the order of the archive. |
| 5103 5104 5105 | XSI | -q | Append the named files to the end of the archive. In this case ar does not check whether the added files are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece by piece. |
| $\begin{aligned} & 5106 \\ & 5107 \\ & 5108 \\ & 5109 \\ & 5110 \\ & 5111 \\ & 50 \end{aligned}$ | xSI | -r | Replace or add files to archive. If the archive named by archive does not exist, a new archive shall be created and a diagnostic message shall be written to standard error (unless the -c option is specified). If no files are specified and the archive exists, the results are undefined. Files that replace existing files in the archive shall not change the order of the archive. Files that do not replace existing files in the archive shall be appended to the archive unless a-a, $\mathbf{- b}$, or $-\mathbf{i}$ option specifies another position |
| 5112 5113 5114 | XSI | -s | Force the regeneration of the archive symbol table even if $a r$ is not invoked with an option that modifies the archive contents. This option is useful to restore the archive symbol table after it has been stripped; see strip. |
| 5115 5116 5117 |  | -t | Write a table of contents of archive to the standard output. The files specified by the file operands shall be included in the written list. If no file operands are specified, all files in archive shall be included in the order of the archive. |
| 5118 5119 5120 5121 | XSI | -T | Allow filename truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long shall be an error; a diagnostic message shall be written and the file shall not be extracted. |
| 5122 5123 5124 |  | -u | Update older files in the archive. When used with the -r option, files in the archive shall be replaced only if the corresponding file has a modification time that is at least as new as the modification time of the file in the archive. |
| 5125 5126 5127 |  | -v | Give verbose output. When used with the option characters $-\mathbf{d},-\mathbf{r}$, or $-\mathbf{x}$, write a detailed file-by-file description of the archive creation and maintenance activity, as described in the STDOUT section. |

When used with $-\mathbf{p}$, write the name of the file in the archive to the standard output before writing the file in the archive itself to the standard output, as described in the STDOUT section.
When used with $-\mathbf{t}$, include a long listing of information about the files in the archive, as described in the STDOUT section.
-x Extract the files in the archive named by the file operands from archive. The contents of the archive shall not be changed. If no file operands are given, all files in the archive shall be extracted. The modification time of each file extracted shall be set to the time the file is extracted from the archive.

## OPERANDS

The following operands shall be supported:
archive A pathname of the archive.
file A pathname. Only the last component shall be used when comparing against the names of files in the archive. If two or more file operands have the same last pathname component (basename), the results are unspecified. The implementation's archive format shall not truncate valid filenames of files added to or replaced in the archive.

XSI
posname $\quad$ Th

## STDIN

Not used.

## INPUT FILES

The archive named by archive shall be a file in the format created by ar $-\mathbf{r}$.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of ar:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME Determine the format and content for date and time strings written by ar -tv.
xSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TMPDIR Determine the pathname that overrides the default directory for temporary files, if any.
$T Z \quad$ Determine the timezone used to calculate date and time strings written by ar $-\mathbf{t v}$. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If the $-\mathbf{d}$ option is used with the $-\mathbf{v}$ option, the standard output format shall be:
" d - \%s\n", <file>
where file is the operand specified on the command line.
If the -p option is used with the $-\mathbf{v}$ option, ar shall precede the contents of each file with:
"\n<\%s>\n\n", <file>
where file is the operand specified on the command line, if file operands were specified, and the name of the file in the archive if they were not.
If the -r option is used with the $-\mathbf{v}$ option:

- If file is already in the archive, the standard output format shall be:
"r - \%s\n", <file>
where <file> is the operand specified on the command line.
- If file is not already in the archive, the standard output format shall be:
"a - \%s\n", <file>
where $\langle$ file $\rangle$ is the operand specified on the command line.
If the $-\mathbf{t}$ option is used, ar shall write the names of the files in the archive to the standard output in the format:

```
"%s\n", <file>
```

where file is the operand specified on the command line, if file operands were specified, or the name of the file in the archive if they were not.
If the $-\mathbf{t}$ option is used with the $-\mathbf{v}$ option, the standard output format shall be:

```
"%s %u/%u %u %s %d %d:%d %d %s\n", <member mode>, <user ID>,
    <group ID>, <number of bytes in member>,
    <abbreviated month>, <day-of-month>, <hour>,
    <minute>, <year>, <file>
```

where:
<file> Shall be the operand specified on the command line, if file operands were specified, or the name of the file in the archive if they were not.

## <member mode>

Shall be formatted the same as the <file mode> string defined in the STDOUT section of $l s$, except that the first character, the <entry type>, is not used; the string represents the file mode of the file in the archive at the time it was added to or replaced in the archive.
The following represent the last-modification time of a file when it was most recently added to or replaced in the archive:
<abbreviated month>
Equivalent to the format of the \%b conversion specification format in date.
<day-of-month> Equivalent to the format of the \%e conversion specification format in date.
<hour> Equivalent to the format of the $\% \mathrm{H}$ conversion specification format in date.
<minute>
<year>
Equivalent to the format of the $\% \mathrm{M}$ conversion specification format in date.

When LC_TIME does not specify the POSIX locale, a different format and order of presentation of these fields relative to each other may be used in a format appropriate in the specified locale.
If the $-\mathbf{x}$ option is used with the $-\mathbf{v}$ option, the standard output format shall be:
"x - \%s\n", <file>
where file is the operand specified on the command line, if file operands were specified, or the name of the file in the archive if they were not.

## STDERR

The standard error shall be used only for diagnostic messages. The diagnostic message about creating a new archive when $-\mathbf{c}$ is not specified shall not modify the exit status.

## OUTPUT FILES

Archives are files with unspecified formats.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The archive format is not described. It is recognized that there are several known ar formats, which are not compatible. The ar utility is included, however, to allow creation of archives that are intended for use only on one machine. The archive is specified as a file, and it can be moved as a file. This does allow an archive to be moved from one machine to another machine that uses the same implementation of ar.
Utilities such as pax (and its forebears tar and cpio) also provide portable "archives". This is a not a duplication; the ar utility is included to provide an interface primarily for make and the compilers, based on a historical model.
In historical implementations, the $-\mathbf{q}$ option (available on XSI-conforming systems) is known to execute quickly because ar does not check on whether the added members are already in the archive. This is useful to bypass the searching otherwise done when creating a large archive piece-by-piece. These remarks may but need not remain true for a brand new implementation of this utility; hence, these remarks have been moved into the RATIONALE.
BSD implementations historically required applications to provide the $-s$ option whenever the archive was supposed to contain a symbol table. As in this volume of IEEE Std 1003.1-200x, System V historically creates or updates an archive symbol table whenever an object file is removed from, added to, or updated in the archive.

The OPERANDS section requires what might seem to be true without specifying it: the archive cannot truncate the filenames below \{NAME_MAX\}. Some historical implementations do so, however, causing unexpected results for the application. Therefore, this volume of IEEE Std 1003.1-200x makes the requirement explicit to avoid misunderstandings.
According to the System V documentation, the options -dmpqrtx are not required to begin with a hyphen $\left({ }^{\prime}-^{\prime}\right)$. This volume of IEEE Std 1003.1-200x requires that a conforming application use the leading hyphen.

The archive format used by the 4.4 BSD implementation is documented in this RATIONALE as an example:

A file created by ar begins with the "magic" string "!<arch> n ". The rest of the archive is made up of objects, each of which is composed of a header for a file, a possible filename, and the file contents. The header is portable between machine architectures, and, if the file contents are printable, the archive is itself printable.
The header is made up of six ASCII fields, followed by a two-character trailer. The fields are the object name ( 16 characters), the file last modification time ( 12 characters), the user and group IDs (each 6 characters), the file mode ( 8 characters), and the file size ( 10 characters). All numeric fields are in decimal, except for the file mode, which is in octal.

The modification time is the file st_mtime field. The user and group IDs are the file st_uid and st_gid fields. The file mode is the file st_mode field. The file size is the file st_size field. The two-byte trailer is the string " <<newline>".
Only the name field has any provision for overflow. If any filename is more than 16 characters in length or contains an embedded space, the string "\#1/" followed by the ASCII length of the name is written in the name field. The file size (stored in the archive header) is incremented by the length of the name. The name is then written immediately following the archive header.
Any unused characters in any of these fields are written as <space>s. If any fields are their particular maximum number of characters in length, there is no separation between the fields.

Objects in the archive are always an even number of bytes long; files that are an odd number of bytes long are padded with a <newline>, although the size in the header does not reflect this.

The ar utility description requires that (when all its members are valid object files) ar produce an object code library, which the linkage editor can use to extract object modules. If the linkage editor needs a symbol table to permit random access to the archive, ar must provide it; however, ar does not require a symbol table.
The BSD -o option was omitted. It is a rare conforming application that uses ar to extract object code from a library with concern for its modification time, since this can only be of importance to make. Hence, since this functionality is not deemed important for applications portability, the modification time of the extracted files is set to the current time.

There is at least one known implementation (for a small computer) that can accommodate only object files for that system, disallowing mixed object and other files. The ability to handle any type of file is not only historical practice for most implementations, but is also a reasonable expectation.
Consideration was given to changing the output format of $a r-\mathbf{t v}$ to the same format as the output of $l s-1$. This would have made parsing the output of $a r$ the same as that of $l s$. This was rejected in part because the current ar format is commonly used and changes would break historical usage. Second, ar gives the user ID and group ID in numeric format separated by a slash. Changing this to be the user name and group name would not be correct if the archive
were moved to a machine that contained a different user database. Since ar cannot know whether the archive was generated on the same machine, it cannot tell what to report.
The text on the -ur option combination is historical practice-since one filename can easily represent two different files (for example, /a/foo and /b/foo), it is reasonable to replace the file in the archive even when the modification time in the archive is identical to that in the file system.

## FUTURE DIRECTIONS

None.
SEE ALSO
c99, date, fort77, pax, strip the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, <unistd.h> description of \{POSIX_NO_TRUNC\}

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the Software Development Utilities option.
The STDOUT description is changed for the $-\mathbf{v}$ option to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.
The $T Z$ entry is added to the ENVIRONMENT VARIABLES section.
IEEE PASC Interpretation 1003.2 \#198 is applied, changing the description to consistently use "file" to refer to a file in the file system hierarchy, "archive" to refer to the archive being operated upon by the ar utility, and "file in the archive" to refer to a copy of a file that is contained in the archive.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/10 is applied, making corrections to the SYNOPSIS. The change was needed since the $-\mathbf{a},-\mathbf{b}$, and $-\mathbf{i}$ options are mutually-exclusive, and posname is required if any of these options is specified.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/11 is applied, correcting the description of the two-byte trailer in RATIONALE which had missed out a backquote. The correct trailer is a backquote followed by a <newline>.

## Issue 7

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME <br> asa - interpret carriage-control characters

## SYNOPSIS

FR asa [file...]

## DESCRIPTION

The asa utility shall write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences in an implementation-defined manner.
The first character of every line shall be removed from the input, and the following actions are performed.
If the character removed is:
<space> The rest of the line is output without change.
$0 \quad$ A <newline> is output, then the rest of the input line.
1 One or more implementation-defined characters that causes an advance to the next page shall be output, followed by the rest of the input line.
$+\quad$ The <newline> of the previous line shall be replaced with one or more implementationdefined characters that causes printing to return to column position 1 , followed by the rest of the input line. If the ' + ' is the first character in the input, it shall be equivalent to <space>.
The action of the asa utility is unspecified upon encountering any character other than those listed above as the first character in a line.

## OPTIONS

None.
OPERANDS
file A pathname of a text file used for input. If no file operands are specified, the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified; see the INPUT FILES section.

## INPUT FILES

The input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of asa:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

The standard output shall be the text from the input file modified as described in the DESCRIPTION section.

## STDERR

None.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were output successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

1. The following command:
asa file
permits the viewing of file (created by a program using FORTRAN-style carriage-control characters) on a terminal.
2. The following command:
```
a.out | asa | lp
```

formats the FORTRAN output of a.out and directs it to the printer.

## RATIONALE

The asa utility is needed to map "standard" FORTRAN 77 output into a form acceptable to contemporary printers. Usually, asa is used to pipe data to the $l p$ utility; see $l p$.

This utility is generally used only by FORTRAN programs. The standard developers decided to retain asa to avoid breaking the historical large base of FORTRAN applications that put carriagecontrol characters in their output files. There is no requirement that a system have a FORTRAN compiler in order to run applications that need asa.

Historical implementations have used an ASCII <form-feed> in response to a 1 and an ASCII <carriage-return> in response to $a^{\prime}+^{\prime}$. It is suggested that implementations treat characters other than 0,1 , and ${ }^{\prime}+^{\prime}$ as <space> in the absence of any compelling reason to do otherwise. However, the action is listed here as "unspecified", permitting an implementation to provide extensions to access fast multiple-line slewing and channel seeking in a non-portable manner.

## FUTURE DIRECTIONS

None.

fort77, lp

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the FORTRAN Runtime Utilities option.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
at - execute commands at a later time

## SYNOPSIS

```
at [-m] [-f file] [-q queuename] -t time_arg
at [-m] [-f file] [-q queuename] timespec...
at -r at_job_id...
at -l -q queuename
    at -l [at_job_id...]
```

## DESCRIPTION

The at utility shall read commands from standard input and group them together as an at-job, to be executed at a later time.

The at-job shall be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask, and other implementation-defined execution-time attributes in effect when the at utility is executed shall be retained and used when the at-job is executed.
When the at-job is submitted, the $a t \_j o b \_i d$ and scheduled time shall be written to standard error. The at_job_id is an identifier that shall be a string consisting solely of alphanumeric characters and the period character. The at_job_id shall be assigned by the system when the job is scheduled such that it uniquely identifies a particular job.
User notification and the processing of the job's standard output and standard error are described under the $-\mathbf{m}$ option.
xSI Users shall be permitted to use at if their name appears in the file at.allow which is located in an implementation-defined directory. If that file does not exist, the file at.deny, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to $a t$. If neither file exists, only a process with the appropriate privileges shall be allowed to submit a job. If only at.deny exists and is empty, global usage shall be permitted. The at.allow and at.deny files shall consist of one user name per line.

## OPTIONS

The at utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-f file Specify the pathname of a file to be used as the source of the at-job, instead of standard input.
-1 (The letter ell.) Report all jobs scheduled for the invoking user if no at_job_id operands are specified. If at_job_ids are specified, report only information for these jobs. The output shall be written to standard output.
$-\mathbf{m} \quad$ Send mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job shall be mailed to the user as well, unless redirected elsewhere. Mail shall be sent even if the job produces no output.
If $-\mathbf{m}$ is not used, the job's standard output and standard error shall be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the implementation need not notify the user of the job's completion.

Specify in which queue to schedule a job for submission. When used with the -1 option, limit the search to that particular queue. By default, at-jobs shall be scheduled in queue $a$. In contrast, queue $b$ shall be reserved for batch jobs; see batch. The meanings of all other queuenames are implementation-defined. If $-\mathbf{q}$ is specified along with either of the $-\mathbf{t}$ time_arg or timespec arguments, the results are unspecified.
-r Remove the jobs with the specified at_job_id operands that were previously scheduled by the at utility.
-t time_arg Submit the job to be run at the time specified by the time option-argument, which the application shall ensure has the format as specified by the touch $-\mathbf{t}$ time utility.

## OPERANDS

The following operands shall be supported:
at_job_id The name reported by a previous invocation of the at utility at the time the job was scheduled.
timespec Submit the job to be run at the date and time specified. All of the timespec operands are interpreted as if they were separated by <space>s and concatenated, and shall be parsed as described in the grammar at the end of this section. The date and time shall be interpreted as being in the timezone of the user (as determined by the $T Z$ variable), unless a timezone name appears as part of time, below.

In the POSIX locale, the following describes the three parts of the time specification string. All of the values from the LC_TIME categories in the POSIX locale shall be recognized in a case-insensitive manner.
time The time can be specified as one, two, or four digits. One-digit and two-digit numbers shall be taken to be hours; four-digit numbers to be hours and minutes. The time can alternatively be specified as two numbers separated by a colon, meaning hour:minute. An AM/PM indication (one of the values from the am_pm keywords in the LC_TIME locale category) can follow the time; otherwise, a 24 -hour clock time shall be understood. A timezone name can also follow to further qualify the time. The acceptable timezone names are implementation-defined, except that they shall be case-insensitive and the string utc is supported to indicate the time is in Coordinated Universal Time. In the POSIX locale, the time field can also be one of the following tokens:
midnight Indicates the time 12:00 am (00:00).
noon Indicates the time 12:00 pm.
now Indicates the current day and time. Invoking at <now> shall submit an at-job for potentially immediate execution (that is, subject only to unspecified scheduling delays).
date An optional date can be specified as either a month name (one of the values from the mon or abmon keywords in the LC_TIME locale category) followed by a day number (and possibly year number preceded by a comma), or a day of the week (one of the values from the day or abday keywords in the LC_TIME locale category). In the POSIX locale, two special days shall be recognized:
the date and time have already occurred this year and the month is not the current month, next year is the assumed year.

## */

\%token year_number
/*
A year_number is a four-digit number representing the year A.D., in
which the at_job is to be run.
*/
\%token inc_number
/*
The inc_number is the number of times the succeeding increment
period is to be added to the specified date and time.
*/
\%token timezone_name
/*
The name of an optional timezone suffix to the time field, in an
implementation-defined format.
*/
\%token month_name
/*
One of the values from the mon or abmon keywords in the LC_TIME
locale category.
*/
\%token day_of_week
/*
One of the values from the day or abday keywords in the LC_TIME

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 29). The standard input shall only be used if no -f file option is specified.

## INPUT FILES

See the STDIN section.
xSI The text files at.allow and at.deny, which are located in an implementation-defined directory, shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the at and batch utilities.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of at:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
XSI

LC_TIME Determine the format and contents for date and time strings written and accepted by at.
SHELL Determine a name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, sh shall be used. If it is set to a value other than a name for sh, the implementation shall do one of the following: use that shell; use sh; use the login shell from the user database; or any of the preceding accompanied by a warning diagnostic about which was chosen.

TZ Determine the timezone. The job shall be submitted for execution at the time specified by timespec or $-\mathbf{t}$ time relative to the timezone specified by the $T Z$ variable. If timespec specifies a timezone, it shall override $T Z$. If timespec does not specify a timezone and $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.

In the POSIX locale, the following shall be written to the standard output for each job when jobs are listed in response to the -1 option:
"\%s
where date shall be equivalent in format to the output of:

```
date +"%a %b %e %T %Y"
```

The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the $T Z$ variable).

## STDERR

In the POSIX locale, the following shall be written to standard error when a job has been successfully submitted:
"job \%s at \%s\n", at_job_id, <date>
where date has the same format as that described in the STDOUT section. Neither this, nor warning messages concerning the selection of the command interpreter, shall be considered a diagnostic that changes the exit status.
Diagnostic messages, if any, shall be written to standard error.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The at utility successfully submitted, removed, or listed a job or jobs.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

The job shall not be scheduled, removed, or listed.

## APPLICATION USAGE

The format of the at command line shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.
Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps, and priority inherited from the invoking environment are lost.

Some implementations do not allow substitution of different shells using SHELL. System V systems, for example, have used the login shell value for the user in /etc/passwd. To select reliably another command interpreter, the user must include it as part of the script, such as:
\$ at 1800
myshell myscript
EOT
job ... at ...
\$

## EXAMPLES

1. This sequence can be used at a terminal:
```
at -m 0730 tomorrow
sort < file >outfile
EOT
```

2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):
```
at now + 1 hour <<!
diff file1 file2 2>&1 >outfile | mailx mygroup
!
```

3. To have a job reschedule itself, at can be invoked from within the at-job. For example, this daily processing script named my.daily runs every day (although crontab is a more appropriate vehicle for such work):
```
# my.daily runs every day
daily processing
at now tomorrow < my.daily
```

4. The spacing of the three portions of the POSIX locale timespec is quite flexible as long as there are no ambiguities. Examples of various times and operand presentation include:
```
at 0815am Jan 24
at 8 :15amjan24
at now "+ 1day"
at 5 pm FRIday
at '17
    utc+
    30minutes'
```

## RATIONALE

The at utility reads from standard input the commands to be executed at a later time. It may be useful to redirect standard output and standard error within the specified commands.
The -t time option was added as a new capability to support an internationalized way of specifying a time for execution of the submitted job.
Early proposals added a "jobname" concept as a way of giving submitted jobs names that are meaningful to the user submitting them. The historical, system-specified at_job_id gives no
indication of what the job is. Upon further reflection, it was decided that the benefit of this was not worth the change in historical interface. The at functionality is useful in simple environments, but in large or complex situations, the functionality provided by the Batch Services option is more suitable.
The $-\mathbf{q}$ option historically has been an undocumented option, used mainly by the batch utility.
The System V -m option was added to provide a method for informing users that an at-job had completed. Otherwise, users are only informed when output to standard error or standard output are not redirected.
The behavior of at <now> was changed in an early proposal from being unspecified to submitting a job for potentially immediate execution. Historical BSD at implementations support this. Historical System V implementations give an error in that case, but a change to the System V versions should have no backwards-compatibility ramifications.
On BSD-based systems, a-u user option has allowed those with appropriate privileges to access the work of other users. Since this is primarily a system administration feature and is not universally implemented, it has been omitted. Similarly, a specification for the output format for a user with appropriate privileges viewing the queues of other users has been omitted.

The $-\mathbf{f}$ file option from System V is used instead of the BSD method of using the last operand as the pathname. The BSD method is ambiguous-does:

```
at 1200 friday
```

mean the same thing if there is a file named friday in the current directory?
The at_job_id is composed of a limited character set in historical practice, and it is mandated here to invalidate systems that might try using characters that require shell quoting or that could not be easily parsed by shell scripts.
The at utility varies between System V and BSD systems in the way timezones are used. On System V systems, the $T Z$ variable affects the at-job submission times and the times displayed for the user. On BSD systems, TZ is not taken into account. The BSD behavior is easily achieved with the current specification. If the user wishes to have the timezone default to that of the system, they merely need to issue the at command immediately following an unsetting or null assignment to TZ. For example:

TZ= at noon ...
gives the desired BSD result.
While the yacc-like grammar specified in the OPERANDS section is lexically unambiguous with respect to the digit strings, a lexical analyzer would probably be written to look for and return digit strings in those cases. The parser could then check whether the digit string returned is a valid day_number, year_number, and so on, based on the context.

## FUTURE DIRECTIONS

None.

## SEE ALSO

## batch, crontab

## CHANGE HISTORY

First released in Issue 2.

## Issue 6

This utility is marked as part of the User Portability Utilities option.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- If $-\mathbf{m}$ is not used, the job's standard output and standard error are provided to the user by mail.
The effects of using the $-\mathbf{q}$ and $-\mathbf{t}$ options as defined in the IEEE P1003.2b draft standard are specified.
The normative text is reworded to avoid use of the term "must" for application requirements.

## Issue 7

The at utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the at utility.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

awk - pattern scanning and processing language

## SYNOPSIS

```
awk [-F ERE] [-v assignment]... program [argument...]
awk [-F ERE] -f progfile [-f progfile]... [-v assignment]...
    [argument...]
```

## DESCRIPTION

The awk utility shall execute programs written in the awk programming language, which is specialized for textual data manipulation. An awk program is a sequence of patterns and corresponding actions. When input is read that matches a pattern, the action associated with that pattern is carried out.
Input shall be interpreted as a sequence of records. By default, a record is a line, less its terminating <newline>, but this can be changed by using the RS built-in variable. Each record of input shall be matched in turn against each pattern in the program. For each pattern matched, the associated action shall be executed.

The awk utility shall interpret each input record as a sequence of fields where, by default, a field is a string of non-<blank>s. This default white-space field delimiter can be changed by using the FS built-in variable or $-\mathbf{F} E R E$. The awk utility shall denote the first field in a record $\$ 1$, the second $\$ 2$, and so on. The symbol $\$ 0$ shall refer to the entire record; setting any other field causes the re-evaluation of $\$ 0$. Assigning to $\$ 0$ shall reset the values of all other fields and the NF builtin variable.

## OPTIONS

The awk utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
$-F E R E$ Define the input field separator to be the extended regular expression $E R E$, before any input is read; see Regular Expressions (on page 161).
-f progfile Specify the pathname of the file progfile containing an awk program. If multiple instances of this option are specified, the concatenation of the files specified as progfile in the order specified shall be the awk program. The awk program can alternatively be specified in the command line as a single argument.

## -v assignment

The application shall ensure that the assignment argument is in the same form as an assignment operand. The specified variable assignment shall occur prior to executing the $a w k$ program, including the actions associated with BEGIN patterns (if any). Multiple occurrences of this option can be specified.

## OPERANDS

The following operands shall be supported:
program If no -f option is specified, the first operand to awk shall be the text of the awk program. The application shall supply the program operand as a single argument to awk. If the text does not end in a <newline>, awk shall interpret the text as if it did.
argument Either of the following two types of argument can be intermixed:
file A pathname of a file that contains the input to be read, which is matched against the set of patterns in the program. If no file operands are specified, or if a file operand is $' \quad-\prime$, the standard input shall be
used.
assignment An operand that begins with an underscore or alphabetic character from the portable character set (see the table in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set), followed by a sequence of underscores, digits, and alphabetics from the portable character set, followed by the $\quad\left(={ }^{\prime}\right.$ character, shall specify a variable assignment rather than a pathname. The characters before the ${ }^{\prime}={ }^{\prime}$ represent the name of an awk variable; if that name is an azk reserved word (see Grammar (on page 169)) the behavior is undefined. The characters following the equal sign shall be interpreted as if they appeared in the awk program preceded and followed by a double-quote ( ${ }^{\prime \prime}$ ') character, as a STRING token (see Grammar (on page 169)), except that if the last character is an unescaped backslash, it shall be interpreted as a literal backslash rather than as the first character of the sequence $" \backslash "$ ". The variable shall be assigned the value of that STRING token and, if appropriate, shall be considered a numeric string (see Expressions in awk (on page 156)), the variable shall also be assigned its numeric value. Each such variable assignment shall occur just prior to the processing of the following file, if any. Thus, an assignment before the first file argument shall be executed after the BEGIN actions (if any), while an assignment after the last file argument shall occur before the END actions (if any). If there are no file arguments, assignments shall be executed before processing the standard input.

## STDIN

The standard input shall be used only if no file operands are specified, or if a file operand is ' ${ }^{\prime}$ '; see the INPUT FLEES section. If the awk program contains no actions and no patterns, but is otherwise a valid $a w k$ program, standard input and any file operands shall not be read and awk shall exit with a return status of zero.

## INPUT FILES

Input files to the $a w k$ program from any of the following sources shall be text files:

- Any file operands or their equivalents, achieved by modifying the awok variables ARGV and ARGC
- Standard input in the absence of any file operands
- Arguments to the getline function

Whether the variable RS is set to a value other than a <newline> or not, for these files, implementations shall support records terminated with the specified separator up to \{LINE_MAX\} bytes and may support longer records.
If $-\mathbf{f}$ progfile is specified, the application shall ensure that the files named by each of the progfile option-arguments are text files and their concatenation, in the same order as they appear in the arguments, is an awk program.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of azwk:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions and in comparisons of string values.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the identification of characters as letters, and the mapping of uppercase and lowercase characters for the toupper and tolower functions.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

## LC_NUMERIC

Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values, and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing awk programs (including assignments in command line arguments).
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the search path when looking for commands executed by system(expr), or input and output pipes; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.
In addition, all environment variables shall be visible via the awk variable ENVIRON.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The nature of the output files depends on the $a w k$ program.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The nature of the output files depends on the awk program.

## EXTENDED DESCRIPTION

## Overall Program Structure

An awk program is composed of pairs of the form:
pattern \{ action \}
Either the pattern or the action (including the enclosing brace characters) can be omitted.
A missing pattern shall match any record of input, and a missing action shall be equivalent to:
\{ print \}
Execution of the $a w k$ program shall start by first executing the actions associated with all BEGIN patterns in the order they occur in the program. Then each file operand (or standard input if no files were specified) shall be processed in turn by reading data from the file until a record separator is seen (<newline> by default). Before the first reference to a field in the record is
evaluated, the record shall be split into fields, according to the rules in Regular Expressions (on page 161), using the value of FS that was current at the time the record was read. Each pattern in the program then shall be evaluated in the order of occurrence, and the action associated with each pattern that matches the current record executed. The action for a matching pattern shall be executed before evaluating subsequent patterns. Finally, the actions associated with all END patterns shall be executed in the order they occur in the program.

## Expressions in awk

Expressions describe computations used in patterns and actions. In the following table, valid expression operations are given in groups from highest precedence first to lowest precedence last, with equal-precedence operators grouped between horizontal lines. In expression evaluation, where the grammar is formally ambiguous, higher precedence operators shall be evaluated before lower precedence operators. In this table expr, expr1, expr2, and expr3 represent any expression, while lvalue represents any entity that can be assigned to (that is, on the left side of an assignment operator). The precise syntax of expressions is given in Grammar (on page 169).

Table 4-1 Expressions in Decreasing Precedence in awk

| Syntax | Name | Type of Result | Associativity |
| :---: | :---: | :---: | :---: |
| ( expr ) | Grouping $>$ | Type of expr | N/A |
| \$expr | Field reference | String | N/A |
| $\begin{aligned} & \text { lvalue ++ } \\ & \text { lvalue -- } \end{aligned}$ | Post-increment Post-decrement | Numeric Numeric | $\begin{aligned} & \mathrm{N} / \mathrm{A} \\ & \mathrm{~N} / \mathrm{A} \end{aligned}$ |
| ++ lvalue <br> -- lvalue | Pre-increment <br> Pre-decrement | Numeric <br> Numeric | $\begin{aligned} & \mathrm{N} / \mathrm{A} \\ & \mathrm{~N} / \mathrm{A} \end{aligned}$ |
| expr ^ expr | Exponentiation | Numeric | Right |
| $\begin{aligned} & \hline \text { !expr } \\ & \text { - expr } \\ & - \text { expr } \end{aligned}$ | Logical not Unary plus Unary minus | Numeric <br> Numeric <br> Numeric | $\begin{aligned} & \text { N/A } \\ & \text { N/A } \\ & \text { N/A } \end{aligned}$ |
| $\begin{array}{\|l\|} \hline \text { expr } \\ \text { expr expr } \\ \text { expr } \% \text { expr } \\ \hline \end{array}$ | Multiplication Division Modulus | Numeric <br> Numeric <br> Numeric | Left Left Left |
| $\begin{aligned} & \text { expr + expr } \\ & \text { expr - expr } \end{aligned}$ | Addition Subtraction | Numeric <br> Numeric | $\begin{aligned} & \text { Left } \\ & \text { Left } \end{aligned}$ |
| expr expr | String concatenation | String | Left |
| $\begin{aligned} & \text { expr < expr } \\ & \text { expr <= expr } \\ & \text { expr ! = expr } \\ & \text { expr == expr } \\ & \text { expr > expr } \\ & \text { expr >= expr } \end{aligned}$ | Less than <br> Less than or equal to <br> Not equal to <br> Equal to <br> Greater than <br> Greater than or equal to | Numeric <br> Numeric <br> Numeric <br> Numeric <br> Numeric <br> Numeric | None <br> None <br> None <br> None <br> None <br> None |
| $\begin{aligned} & \text { expr } \sim \text { expr } \\ & \text { expr ! } \sim \text { expr } \end{aligned}$ | ERE match ERE non-match | Numeric <br> Numeric | None <br> None |
| $\begin{aligned} & \text { expr in array } \\ & \text { ( index ) in array } \end{aligned}$ | Array membership Multi-dimension array membership | Numeric Numeric | Left Left |
| expr \&\& expr | Logical AND | Numeric | Left |
| expr \|| expr | Logical OR | Numeric | Left |

| Syntax | Name | Type of Result | Associativity |
| :--- | :--- | :--- | :--- |
| expr1 ? expr2 : expr3 | Conditional expression | Type of selected <br> expr2 or expr3 | Right |
| lvalue ^= expr | Exponentiation assignment | Numeric | Right |
| lvalue \%= expr | Modulus assignment | Numeric | Right |
| lvalue *=expr | Multiplication assignment | Numeric | Right |
| lvalue /= expr | Division assignment | Numeric | Right |
| lvalue += expr | Addition assignment | Numeric | Right |
| lvalue ==expr | Subtraction assignment | Numeric | Right |
| lvalue =expr | Assignment | Type of expr | Right |

Each expression shall have either a string value, a numeric value, or both. Except as stated for specific contexts, the value of an expression shall be implicitly converted to the type needed for the context in which it is used. A string value shall be converted to a numeric value by the equivalent of the following calls to functions defined by the ISO C standard:

```
setlocale(LC_NUMERIC, "");
numeric_value = atof(string_value);
```

A numeric value that is exactly equal to the value of an integer (see Section 1.7.2 (on page 7)) shall be converted to a string by the equivalent of a call to the sprintf function (see String Functions (on page 166)) with the string "\%d" as the fmt argument and the numeric value being converted as the first and only expr argument. Any other numeric value shall be converted to a string by the equivalent of a call to the sprintf function with the value of the variable CONVFMT as the fmt argument and the numeric value being converted as the first and only expr argument. The result of the conversion is unspecified if the value of CONVFMT is not a floating-point format specification. This volume of IEEE Std 1003,1-200x specifies no explicit conversions between numbers and strings. An application can force an expression to be treated as a number by adding zero to $i t$, or can force it to be treated as a string by concatenating the null string (" ") to it.
A string value shall be considered a numeric string if it comes from one of the following:

1. Field variables
2. Input from the getline() function
3. FILENAME
4. ARGV array elements
5. ENVIRON array elements
6. Array elements created by the split ( ) function
7. A command line variable assignment
8. Variable assignment from another numeric string variable
and after all the following conversions have been applied, the resulting string would lexically be recognized as a NUMBER token as described by the lexical conventions in Grammar (on page 169):

- All leading and trailing <blank>s are discarded.
- If the first non-<blank> is ' + ' or ' - ' , it is discarded.
- Changing each occurrence of the decimal point character from the current locale to a period.
If a ${ }^{\prime} \boldsymbol{\prime}^{\prime}$ character is ignored in the preceding description, the numeric value of the numeric string shall be the negation of the numeric value of the recognized NUMBER token. Otherwise, the
numeric value of the numeric string shall be the numeric value of the recognized NUMBER token. Whether or not a string is a numeric string shall be relevant only in contexts where that term is used in this section.
When an expression is used in a Boolean context, if it has a numeric value, a value of zero shall be treated as false and any other value shall be treated as true. Otherwise, a string value of the null string shall be treated as false and any other value shall be treated as true. A Boolean context shall be one of the following:
- The first subexpression of a conditional expression
- An expression operated on by logical NOT, logical AND, or logical OR
- The second expression of a for statement
- The expression of an if statement
- The expression of the while clause in either a while or do...while statement
- An expression used as a pattern (as in Overall Program Structure)

All arithmetic shall follow the semantics of floating-point arithmetic as specified by the ISO C standard (see Section 1.7.2 (on page 7)).

The value of the expression:
expr1 ^ expr2
shall be equivalent to the value returned by the ISO C standard function call:
pow (expr1, expr2)
The expression:

```
lvalue ^= expr
```

shall be equivalent to the ISO C standard expression:

```
lvalue = pow(lvalue, expr)
```

except that lvalue shall be evaluated only once. The value of the expression:

```
expr1 % expr2
```

shall be equivalent to the value returned by the ISO C standard function call:

```
fmod(expr1, expr2)
```

The expression:

```
lvalue %= expr
```

shall be equivalent to the ISO $C$ standard expression:

```
lvalue = fmod(lvalue, expr)
```

except that lvalue shall be evaluated only once.
Variables and fields shall be set by the assignment statement:

```
lvalue = expression
```

and the type of expression shall determine the resulting variable type. The assignment includes the arithmetic assignments ("+=", "-=", "*=", "/=", "\%=", " "=", "++", "--") all of which shall produce a numeric result. The left-hand side of an assignment and the target of increment and decrement operators can be one of a variable, an array with index, or a field selector.
The awk language supplies arrays that are used for storing numbers or strings. Arrays need not be declared. They shall initially be empty, and their sizes shall change dynamically. The
subscripts, or element identifiers, are strings, providing a type of associative array capability. An array name followed by a subscript within square brackets can be used as an lvalue and thus as an expression, as described in the grammar; see Grammar (on page 169). Unsubscripted array names can be used in only the following contexts:

## - A parameter in a function definition or function call

- The NAME token following any use of the keyword in as specified in the grammar (see Grammar (on page 169)); if the name used in this context is not an array name, the behavior is undefined

A valid array index shall consist of one or more comma-separated expressions, similar to the way in which multi-dimensional arrays are indexed in some programming languages. Because awk arrays are really one-dimensional, such a comma-separated list shall be converted to a single string by concatenating the string values of the separate expressions, each separated from the other by the value of the SUBSEP variable. Thus, the following two index operations shall be equivalent:

```
var[expr1, expr2, ... exprn]
var[expr1 SUBSEP expr2 SUBSEP ... SUBSEP exprn]
```

The application shall ensure that a multi-dimensioned index used with the in operator is parenthesized. The in operator, which tests for the existence of a particular array element, shall not cause that element to exist. Any other reference to a nonexistent array element shall automatically create it.

Comparisons (with the $\quad<^{\prime}, \quad "<=", "!=", "==", \quad>^{\prime}$, and $">=$ " operators) shall be made numerically if both operands are numeric, if one is numeric and the other has a string value that is a numeric string, or if one is numeric and the other has the uninitialized value. Otherwise, operands shall be converted to strings as required and a string comparison shall be made using the locale-specific collation sequence. The value of the comparison expression shall be 1 if the relation is true, or 0 if the relation is false.

## Variables and Special Variables

Variables can be used in an awk program by referencing them. With the exception of function parameters (see User-Defined Functions (on page 169)), they are not explicitly declared. Function parameter names shall be local to the function; all other variable names shall be global. The same name shall not be used as both a function parameter name and as the name of a function or a special avok variable. The same name shall not be used both as a variable name with global scope and as the name of a function. The same name shall not be used within the same scope both as a scalar variable and as an array. Uninitialized variables, including scalar variables, array elements, and field variables, shall have an uninitialized value. An uninitialized value shall have both a numeric value of zero and a string value of the empty string. Evaluation of variables with an uninitialized value, to either string or numeric, shall be determined by the context in which they are used.

Field variables shall be designated by a ' $\$$ ' followed by a number or numerical expression. The effect of the field number expression evaluating to anything other than a non-negative integer is unspecified; uninitialized variables or string values need not be converted to numeric values in this context. New field variables can be created by assigning a value to them. References to nonexistent fields (that is, fields after \$NF), shall evaluate to the uninitialized value. Such references shall not create new fields. However, assigning to a nonexistent field (for example, $\$(\mathrm{NF}+2)=5)$ shall increase the value of NF; create any intervening fields with the uninitialized value; and cause the value of $\$ 0$ to be recomputed, with the fields being separated by the value of OFS. Each field variable shall have a string value or an uninitialized value when created. Field variables shall have the uninitialized value when created from $\$ 0$ using FS and the variable does not contain any characters. If appropriate, the field variable shall be considered a numeric

| 6131 | string (see Expressions in awk (on page 156)). |  |
| :---: | :---: | :---: |
| 6132 | Implementations shall support the following other special variables that are set by $a w k$ : |  |
| 6133 | ARGC | The number of elements in the ARGV array. |
| 6135 | ARGV | An array of command line arguments, excluding options and the program argument, numbered from zero to ARGC-1. |
| 6136 6137 6138 6139 6140 6141 6142 |  | The arguments in ARGV can be modified or added to; ARGC can be altered. As each input file ends, awk shall treat the next non-null element of ARGV, up to the current value of ARGC-1, inclusive, as the name of the next input file. Thus, setting an element of ARGV to null means that it shall not be treated as an input file. The name ' - ' indicates the standard input. If an argument matches the format of an assignment operand, this argument shall be treated as an assignment rather than a file argument. |
| 6144 | CONVFMT | The printf format for converting numbers to strings (except for output statements, where OFMT is used); " $\% .6 \mathrm{~g}$ " by default. |
| 6146 6147 6148 6149 6150 6151 | ENVIRON | An array representing the value of the environment, as described in the exec functions defined in the System Interfaces volume of IEEE Std 1003.1-200x. The indices of the array shall be strings consisting of the names of the environment variables, and the value of each array element shall be a string consisting of the value of that variable. If appropriate, the environment variable shall be considered a numeric string (see Expressions in awk (on page 156)); the array element shall also have its numeric value. |
| 6154 6155 6156 6157 |  | In all cases where the behavior of azwk is affected by environment variables (including the environment of any commands that azwk executes via the system function or via pipeline redirections with the print statement, the printf statement, or the getline function), the environment used shall be the environment at the time $a w k$ began executing; it is implementation-defined whether any modification of ENVIRON affects this environment. |
| 6159 6160 | FILENAME | A pathname of the current input file. Inside a BEGIN action the value is undefined. Inside an END action the value shall be the name of the last input file processed. |
| 6162 6163 | FNR | The ordinal number of the current record in the current file. Inside a BEGIN action the value shall be zero. Inside an END action the value shall be the number of the last record processed in the last file processed. |
| 6164 | FS | Input field separator regular expression; a <space> by default. |
| 6165 6166 6167 6168 6169 | NF | The number of fields in the current record. Inside a BEGIN action, the use of NF is undefined unless a getline function without a var argument is executed previously. Inside an END action, NF shall retain the value it had for the last record read, unless a subsequent, redirected, getline function without a var argument is performed prior to entering the END action. |
| 6170 617 6172 | NR | The ordinal number of the current record from the start of input. Inside a BEGIN action the value shall be zero. Inside an END action the value shall be the number of the last record processed. |
| 6173 6174 | OFMT | The printf format for converting numbers to strings in output statements (see Output Statements (on page 164)); "\%. $6 \mathrm{~g} "$ by default. The result of the conversion is unspecified if the value of OFMT is not a floating-point format specification. | is unspecified if the value of OFMT is not a floating-point format specification.

OFS The print statement output field separator; <space> by default.
ORS
RLENGTH
RS
put record separator; a <newline> by default. If RS contains more than one character, the results are unspecified. If RS is null, then records are separated by sequences consisting of a <newline> plus one or more blank lines, leading or trailing blank lines shall not result in empty records at the beginning or end of the input, and a <newline> shall always be a field separator, no matter what the value of FS is.
RSTART The starting position of the string matched by the match function, numbering from 1. This shall always be equivalent to the return value of the match function.

SUBSEP The subscript separator string for multi-dimensional arrays; the default value is implementation-defined.

## Regular Expressions

The awk utility shall make use of the extended regular expression notation (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions) except that it shall allow the use of C-language conventions for escaping special characters within the EREs, as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5,
 table; these escape sequences shall be recognized both inside and outside bracket expressions. Note that records need not be separated by <newline>s and string constants can contain <newline>s, so even the " $\backslash \mathrm{n}$ " sequence is valid in awk EREs. Using a slash character within an ERE requires the escaping shown in the following table.

Table 4-2 Escape Sequences in awk

| Escape Sequence | Description | Meaning |
| :---: | :---: | :---: |
| \" | Backslash quotation-mark | Quotation-mark character |
| \/ | Backslash slash | Slash character |
| \ddd | A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined. | The character whose encoding is represented by the one, two, or threedigit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading ' $\backslash$ ' for each byte. |
| \c | A backslash character followed by any character not described in this table or in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation (' $\backslash \backslash^{\prime}, ~ ' ~ \backslash \mathrm{a}^{\prime}, ~ ' \backslash \mathrm{~b} '$, $\left.' \backslash \mathrm{f}^{\prime},{ }^{\prime} \backslash \mathrm{n}^{\prime}, ' \backslash \mathrm{r}^{\prime}, \prime \backslash \mathrm{t}^{\prime},{ }^{\prime} \backslash \mathrm{v}^{\prime}\right)$. | Undefined |

A regular expression can be matched against a specific field or string by using one of the two regular expression matching operators, $\quad \sim$ and "! " . These operators shall interpret their right-hand operand as a regular expression and their left-hand operand as a string. If the regular expression matches the string, the $\sim$ ' expression shall evaluate to a value of 1 , and the "! ~" expression shall evaluate to a value of 0 . (The regular expression matching operation is as defined by the term matched in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.1, Regular Expression Definitions, where a match occurs on any part of the string unless the regular expression is limited with the circumflex or dollar sign special characters.) If the regular expression does not match the string, the ${ }^{\prime \sim}$ expression shall evaluate to a value of 0 , and the "! ~" expression shall evaluate to a value of 1 . If the right-hand operand is any expression other than the lexical token ERE, the string value of the expression shall be interpreted as an extended regular expression, including the escape conventions described above. Note that these same escape conventions shall also be applied in determining the value of a string literal (the lexical token STRING), and thus shall be applied a second time when a string literal is used in this context.

When an ERE token appears as an expression in any context other than as the right-hand of the , ~' or "! ~" operator or as one of the built-in function arguments described below, the value of the resulting expression shall be the equivalent of:

```
$0 ~ /ere/
```

The ere argument to the gsub, match, sub functions, and the $f s$ argument to the split function (see String Functions (on page 166)) shall be interpreted as extended regular expressions. These can be either ERE tokens or arbitrary expressions, and shall be interpreted in the same manner as the right-hand side of the $\quad \sim^{\prime}$ or " ! ~" operator.
An extended regular expression can be used to separate fields by using the $-F E R E$ option or by assigning a string containing the expression to the built-in variable FS. The default value of the FS variable shall be a single <space>. The following describes FS behavior:

1. If FS is a null string, the behavior is unspecified.
2. If FS is a single character:
a. If FS is <space>, skip leading and trailing <blank>s; fields shall be delimited by sets of one or more <blank>s.
b. Otherwise, if FS is any other character $c$, fields shall be delimited by each single occurrence of $c$.
3. Otherwise, the string value of FS shall be considered to be an extended regular expression. Each occurrence of a sequence matching the extended regular expression shall delimit fields.
Except for the $\quad \sim$, and " ! ~" operators, and in the gsub, match, split, and sub built-in functions, ERE matching shall be based on input records; that is, record separator characters (the first character of the value of the variable RS, <newline> by default) cannot be embedded in the expression, and no expression shall match the record separator character. If the record separator is not <newline>, <newline>s embedded in the expression can be matched. For the $\quad \sim$, and "! ~" operators, and in those four built-in functions, ERE matching shall be based on text strings; that is, any character (including <newline> and the record separator) can be embedded in the pattern, and an appropriate pattern shall match any character. However, in all awk ERE matching, the use of one or more NUL characters in the pattern, input record, or text string produces undefined results.

## Patterns

A pattern is any valid expression, a range specified by two expressions separated by a comma, or one of the two special patterns BEGIN or END.

## Special Patterns

The awk utility shall recognize two special patterns, BEGIN and END. Each BEGIN pattern shall be matched once and its associated action executed before the first record of input is read (except possibly by use of the getline function-see Input/Output and General Functions (on page 168) -in a prior BEGIN action) and before command line assignment is done. Each END pattern shall be matched once and its associated action executed after the last record of input has been read. These two patterns shall have associated actions.
BEGIN and END shall not combine with other patterns. Multiple BEGIN and END patterns shall be allowed. The actions associated with the BEGIN patterns shall be executed in the order specified in the program, as are the END actions. An END pattern can precede a BEGIN pattern in a program.
If an awk program consists of only actions with the pattern BEGIN, and the BEGIN action contains no getline function, awk shall exit without reading its input when the last statement in the last BEGIN action is executed. If an awk program consists of only actions with the pattern END or only actions with the patterns BEGIN and END, the input shall be read before the statements in the END actions are executed.

## Expression Patterns

An expression pattern shall be evaluated as if it were an expression in a Boolean context. If the result is true, the pattern shall be considered to match, and the associated action (if any) shall be executed. If the result is false, the action shall not be executed.

## Pattern Ranges

A pattern range consists of two expressions separated by a comma; in this case, the action shall be performed for all records between a match of the first expression and the following match of the second expression, inclusive. At this point, the pattern range can be repeated starting at input records subsequent to the end of the matched range.

## Actions

An action is a sequence of statements as shown in the grammar in Grammar (on page 169). Any single statement can be replaced by a statement list enclosed in braces. The application shall ensure that statements in a statement list are separated by <newline>s or semicolons. Statements in a statement list shall be executed sequentially in the order that they appear.
The expression acting as the conditional in an if statement shall be evaluated and if it is non-zero or non-null, the following statement shall be executed; otherwise, if else is present, the statement following the else shall be executed.
The if, while, do...while, for, break, and continue statements are based on the ISO C standard (see Section 1.7.2 (on page 7)), except that the Boolean expressions shall be treated as described in Expressions in awk (on page 156), and except in the case of:

```
for (variable in array)
```

which shall iterate, assigning each index of array to variable in an unspecified order. The results of adding new elements to array within such a for loop are undefined. If a break or continue statement occurs outside of a loop, the behavior is undefined.
The delete statement shall remove an individual array element. Thus, the following code deletes an entire array:

```
for (index in array)
    delete array[index]
```

The next statement shall cause all further processing of the current input record to be abandoned. The behavior is undefined if a next statement appears or is invoked in a BEGIN or END action.

The exit statement shall invoke all END actions in the order in which they occur in the program source and then terminate the program without reading further input. An exit statement inside an END action shall terminate the program without further execution of END actions. If an expression is specified in an exit statement, its numeric value shall be the exit status of awk, unless subsequent errors are encountered or a subsequent exit statement with an expression is executed.

## Output Statements

Both print and printf statements shall write to standard output by default. The output shall be written to the location specified by output_redirection if one is supplied, as follows:

```
> expression
>> expression
| expression
```

In all cases, the expression shall be evaluated to produce a string that is used as a pathname into which to write (for ${ }^{\prime}>^{\prime}$ or " $\gg{ }^{\prime}$ ") or as a command to be executed (for ${ }^{\prime} \mid '$ ). Using the first two forms, if the file of that name is not currently open, it shall be opened, creating it if necessary and using the first form, truncating the file. The output then shall be appended to the file. As long as the file remains open, subsequent calls in which expression evaluates to the same string value shall simply append output to the file. The file remains open until the close function (see Input/Output and General Functions (on page 168)) is called with an expression that evaluates
to the same string value.
The third form shall write output onto a stream piped to the input of a command. The stream shall be created if no stream is currently open with the value of expression as its command name. The stream created shall be equivalent to one created by a call to the popen () function defined in the System Interfaces volume of IEEE Std 1003.1-200x with the value of expression as the command argument and a value of $w$ as the mode argument. As long as the stream remains open, subsequent calls in which expression evaluates to the same string value shall write output to the existing stream. The stream shall remain open until the close function (see Input/Output and General Functions (on page 168)) is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the pclose() function defined in the System Interfaces volume of IEEE Std 1003.1-200x.
As described in detail by the grammar in Grammar (on page 169), these output statements shall take a comma-separated list of expressions referred to in the grammar by the non-terminal symbols expr_list, print_expr_list, or print_expr_list_opt. This list is referred to here as the expression list, and each member is referred to as an expression argument.
The print statement shall write the value of each expression argument onto the indicated output stream separated by the current output field separator (see variable OFS above), and terminated by the output record separator (see variable ORS above). All expression arguments shall be taken as strings, being converted if necessary; this conversion shall be as described in Expressions in awk (on page 156), with the exception that the printf format in OFMT shall be used instead of the value in CONVFMT. An empty expression list shall stand for the whole input record (\$0).

The printf statement shall produce output based on a notation similar to the File Format Notation used to describe file formats in this volume of IEEE Std 1003.1-200x (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation). Output shall be produced as specified with the first expression argument as the string format and subsequent expression arguments as the strings arg 1 to argn, inclusive, with the following exceptions:

1. The format shall be an actual character string rather than a graphical representation. Therefore, it cannot contain empty character positions. The <space> in the format string, in any context other than a flag of a conversion specification, shall be treated as an ordinary character that is copied to the output.
2. If the character set contains a ' $\Delta^{\prime}$ character and that character appears in the format string, it shall be treated as an ordinary character that is copied to the output.
3. The escape sequences beginning with a backslash character shall be treated as sequences of ordinary characters that are copied to the output. Note that these same sequences shall be interpreted lexically by awk when they appear in literal strings, but they shall not be treated specially by the printf statement.
4. A field width or precision can be specified as the ${ }^{\prime *}$ ' character instead of a digit string. In this case the next argument from the expression list shall be fetched and its numeric value taken as the field width or precision.
5. The implementation shall not precede or follow output from the $d$ or $u$ conversion specifier characters with <blank>s not specified by the format string.
6. The implementation shall not precede output from the o conversion specifier character with leading zeros not specified by the format string.
7. For the conversion specifier character: if the argument has a numeric value, the character whose encoding is that value shall be output. If the value is zero or is not the encoding of any character in the character set, the behavior is undefined. If the argument does not have a numeric value, the first character of the string value shall be output; if the string does not contain any characters, the behavior is undefined.
8. For each conversion specification that consumes an argument, the next expression argument shall be evaluated. With the exception of the c conversion specifier character, the value shall be converted (according to the rules specified in Expressions in awk (on page 156)) to the appropriate type for the conversion specification.
9. If there are insufficient expression arguments to satisfy all the conversion specifications in the format string, the behavior is undefined.
10. If any character sequence in the format string begins with a ${ }^{\prime} \%$ character, but does not form a valid conversion specification, the behavior is unspecified.

Both print and printf can output at least \{LINE_MAX\} bytes.

## Functions

The awk language has a variety of built-in functions: arithmetic, string, input/output, and general.

## Arithmetic Functions

The arithmetic functions, except for int, shall be based on the ISO C standard (see Section 1.7.2 (on page 7)). The behavior is undefined in cases where the ISO C standard specifies that an error be returned or that the behavior is undefined. Although the grammar (see Grammar (on page 169)) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the " []" brackets), such use is undefined.
$\operatorname{atan} \mathbf{2}(y, x) \quad$ Return arctangent of $y / x$ in radians in the range $[-\pi, \pi]$.
$\boldsymbol{\operatorname { c o s }}(x) \quad$ Return cosine of $x$, where $x$ is in radians.
$\sin (x) \quad$ Return sine of $x$, where $x$ is in radians.
$\exp (x) \quad$ Return the exponential function of $x$.
$\log (x) \quad$ Return the natural logarithm of $x$.
$\operatorname{sqrt}(x) \quad$ Return the square root of $x$.
$\operatorname{int}(x) \quad$ Return the argument truncated to an integer. Truncation shall be toward 0 when $x>0$.
$\operatorname{rand}() \quad$ Return a random number $n$, such that $0 \leq n<1$.
$\operatorname{srand}([$ expr $])$ Set the seed value for rand to expr or use the time of day if expr is omitted. The previous seed value shall be returned.

## String Functions

The string functions in the following list shall be supported. Although the grammar (see Grammar (on page 169)) permits built-in functions to appear with no arguments or parentheses, unless the argument or parentheses are indicated as optional in the following list (by displaying them within the " [ ] " brackets), such use is undefined.
gsub(ere, repl[, in])
Behave like sub (see below), except that it shall replace all occurrences of the regular expression (like the ed utility global substitute) in $\$ 0$ or in the in argument, when specified.
index $(s, t) \quad$ Return the position, in characters, numbering from 1, in string $s$ where string $t$ first occurs, or zero if it does not occur at all.
length $[([s])]$ Return the length, in characters, of its argument taken as a string, or of the whole record, $\$ 0$, if there is no argument.
match(s,ere) Return the position, in characters, numbering from 1, in string $s$ where the extended regular expression ere occurs, or zero if it does not occur at all. RSTART shall be set to the starting position (which is the same as the returned value), zero if no match is found; RLENGTH shall be set to the length of the matched string, -1 if no match is found.
$\operatorname{split}\left(s, a\left[, f_{s}\right]\right)$
Split the string $s$ into array elements $a[1], a[2], \ldots, a[n]$, and return $n$. All elements of the array shall be deleted before the split is performed. The separation shall be done with the ERE $f s$ or with the field separator $\mathbf{F S}$ if $f_{s}$ is not given. Each array element shall have a string value when created and, if appropriate, the array element shall be considered a numeric string (see Expressions in awk (on page 156)). The effect of a null string as the value of $f s$ is unspecified.
$\operatorname{sprintf}(f m t$, expr, expr, ...)
Format the expressions according to the printf format given by fmt and return the resulting string.
sub(ere, repl[, in ])
Substitute the string repl in place of the first instance of the extended regular expression $E R E$ in string in and return the number of substitutions. An ampersand ( ${ }^{\prime} \delta^{\prime}$ ) appearing in the string repl shall be replaced by the string from in that matches the ERE. An ampersand preceded with a backslash (' $\backslash^{\prime}$ ) shall be interpreted as the literal ampersand character. An occurrence of two consecutive backslashes shall be interpreted as just a single literal backslash character. Any other occurrence of a backslash (for example, preceding any other character) shall be treated as a literal backslash character. Note that if repl is a string literal (the lexical token STRING; see Gramman (on page 169)), the handling of the ampersand character occurs after any lexical processing, including any lexical backslash escape sequence processing. If in is specified and it is not an lvalue (see Expressions in awk (on page 156)), the behavior is undefined. If in is omitted, awk shall use the current record ( $\$ 0$ ) in its place.
$\operatorname{substr}(s, m[\boxed{m}])$
Return the at most $n$-character substring of $s$ that begins at position $m$, numbering from 1. If $n$ is omitted, or if $n$ specifies more characters than are left in the string, the length of the substring shall be limited by the length of the string $s$.
tolower(s) Return a string based on the string s. Each character in $s$ that is an uppercase letter specified to have a tolower mapping by the LC_CTYPE category of the current locale shall be replaced in the returned string by the lowercase letter specified by the mapping. Other characters in $s$ shall be unchanged in the returned string.
toupper(s) Return a string based on the string $s$. Each character in $s$ that is a lowercase letter specified to have a toupper mapping by the LC_CTYPE category of the current locale is replaced in the returned string by the uppercase letter specified by the mapping. Other characters in $s$ are unchanged in the returned string.
All of the preceding functions that take $E R E$ as a parameter expect a pattern or a string valued expression that is a regular expression as defined in Regular Expressions (on page 161).

## Input/Output and General Functions

The input/output and general functions are:
close(expression)
Close the file or pipe opened by a print or printf statement or a call to getline with the same string-valued expression. The limit on the number of open expression arguments is implementation-defined. If the close was successful, the function shall return zero; otherwise, it shall return non-zero.

## expression | getline [var]

Read a record of input from a stream piped from the output of a command. The stream shall be created if no stream is currently open with the value of expression as its command name. The stream created shall be equivalent to one created by a call to the popen ( ) function with the value of expression as the command argument and a value of $r$ as the mode argument. As long as the stream remains open, subsequent calls in which expression evaluates to the same string value shall read subsequent records from the stream. The stream shall remain open until the close function is called with an expression that evaluates to the same string value. At that time, the stream shall be closed as if by a call to the pclose ( ) function. If var is omitted, \$0 and NF shall be set; otherwise, var shall be set and, if appropriate, it shall be considered a numeric string (see Expressions in awk (on page 156)).

The getline operator can form ambiguous constructs when there are unparenthesized operators (including concatenate) to the left of the ' $\mid$ ' (to the beginning of the expression containing getline). In the context of the ' $\$$ ' operator, ' $\mid$ ' shall behave as if it had a lower precedence than ' $\$^{\prime}$. The result of evaluating other operators is unspecified, and conforming applications shall parenthesize properly all such usages.
getline Set $\$ 0$ to the next input record from the current input file. This form of getline shall set the NF, NR, and FNR variables.
getline var Set variable var to the next input record from the current input file and, if appropriate, var shall be considered a numeric string (see Expressions in awk (on page 156)). This form of getline shall set the FNR and NR variables.
getline [var] < expression
Read the next record of input from a named file. The expression shall be evaluated to produce a string that is used as a pathname. If the file of that name is not currently open, it shall be opened. As long as the stream remains open, subsequent calls in which expression evaluates to the same string value shall read subsequent records from the file. The file shall remain open until the close function is called with an expression that evaluates to the same string value. If var is omitted, $\$ 0$ and NF shall be set; otherwise, var shall be set and, if appropriate, it shall be considered a numeric string (see Expressions in awk (on page 156)).
The getline operator can form ambiguous constructs when there are unparenthesized binary operators (including concatenate) to the right of the ' <' (up to the end of the expression containing the getline). The result of evaluating such a construct is unspecified, and conforming applications shall parenthesize properly all such usages.
system(expression)
Execute the command given by expression in a manner equivalent to the system () function defined in the System Interfaces volume of IEEE Std 1003.1-200x and return the exit status of the command.
All forms of getline shall return 1 for successful input, zero for end-of-file, and -1 for an error.

Where strings are used as the name of a file or pipeline, the application shall ensure that the strings are textually identical. The terminology "same string value" implies that "equivalent strings", even those that differ only by <space>s, represent different files.

## User-Defined Functions

The awk language also provides user-defined functions. Such functions can be defined as:

```
function name([parameter, ...]) { statements }
```

A function can be referred to anywhere in an $a w k$ program; in particular, its use can precede its definition. The scope of a function is global.
Function parameters, if present, can be either scalars or arrays; the behavior is undefined if an array name is passed as a parameter that the function uses as a scalar, or if a scalar expression is passed as a parameter that the function uses as an array. Function parameters shall be passed by value if scalar and by reference if array name.
The number of parameters in the function definition need not match the number of parameters in the function call. Excess formal parameters can be used as local variables. If fewer arguments are supplied in a function call than are in the function definition, the extra parameters that are used in the function body as scalars shall evaluate to the uninitialized value until they are otherwise initialized, and the extra parameters that are used in the function body as arrays shall be treated as uninitialized arrays where each element evaluates to the uninitialized value until otherwise initialized.

When invoking a function, no white space can be placed between the function name and the opening parenthesis. Function calls can be nested and recursive calls can be made upon functions. Upon return from any nested or recursive function call, the values of all of the calling function's parameters shall be unchanged, except for array parameters passed by reference. The return statement can be used to return a value. If a return statement appears outside of a function definition, the behavior is undefined.
In the function definition, <newline>s shall be optional before the opening brace and after the closing brace. Function definitions can appear anywhere in the program where a pattern-action pair is allowed.

## Grammar

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for awk programs. The general conventions for this style of grammar are described in Section 1.10 (on page 18). A valid program can be represented as the non-terminal symbol program in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

This grammar has several ambiguities that shall be resolved as follows:

- Operator precedence and associativity shall be as described in Table 4-1 (on page 156).
- In case of ambiguity, an else shall be associated with the most immediately preceding if that would satisfy the grammar.
- In some contexts, a slash (' $\chi^{\prime}$ ) that is used to surround an ERE could also be the division operator. This shall be resolved in such a way that wherever the division operator could appear, a slash is assumed to be the division operator. (There is no unary division operator.)
Each expression in an awk program shall conform to the precedence and associativity rules, even when this is not needed to resolve an ambiguity. For example, because '\$' has higher

```

``` unambiguously parsed by the grammar as " \(\$(x++)--{ }^{\prime}\).
One convention that might not be obvious from the formal grammar is where <newline>s are acceptable. There are several obvious placements such as terminating a statement, and a backslash can be used to escape <newline>s between any lexical tokens. In addition, <newline>s without backslashes can follow a comma, an open brace, logical AND operator (" \(\alpha \&\) "), logical OR operator ( \("|\mid "\) ), the do keyword, the else keyword, and the closing parenthesis of an if, for, or while statement. For example:
\{ print \(\$ 1\),
\$2 \}
```

## Lexical Conventions

The lexical conventions for awk programs, with respect to the preceding grammar, shall be as follows:

1. Except as noted, awk shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the number sign character and terminated by, but excluding the next occurrence of, a <newline>. Comments shall have no effect, except to delimit lexical tokens.
3. The <newline> shall be recognized as the token NEWLINE.
4. A backslash character immediately followed by a <newline> shall have no effect.
5. The token STRING shall represent a string constant. A string constant shall begin with the character ' "'. Within a string constant, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation $\left({ }^{\prime} \backslash \backslash^{\prime}, ~ ' \backslash \mathrm{a}^{\prime},^{\prime} \backslash \mathrm{b}^{\prime}, ~ ' \backslash \mathrm{f}^{\prime}, ~ ' \backslash \mathrm{n}^{\prime}\right.$, $\left.' \backslash r^{\prime}, ' \backslash t^{\prime}, ' \backslash v^{\prime}\right)$. In addition, the escape sequences in Table $4-2$ shall be recognized. A <newline> shall not occur within a string constant. A string constant shall be terminated by the first unescaped occurrence of the character ${ }^{\prime \prime \prime}$ ' after the one that begins the string constant. The value of the string shall be the sequence of all unescaped characters and values of escape sequences between, but not including, the two delimiting ' "' characters.
6. The token ERE represents an extended regular expression constant. An ERE constant shall begin with the slash character. Within an ERE constant, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation. In addition, the escape sequences in Table 4-2 shall be recognized. The application shall ensure that a <newline> does not occur within an ERE constant. An ERE constant shall be terminated by the first unescaped occurrence of the slash character after the one that begins the ERE constant. The extended regular expression represented by the ERE constant shall be the sequence of all unescaped characters and values of escape sequences between, but not including, the two delimiting slash characters.
7. A <blank $>$ shall have no effect, except to delimit lexical tokens or within STRING or ERE tokens.
8. The token NUMBER shall represent a numeric constant. Its form and numeric value shall be equivalent to either of the tokens floating-constant or integer-constant as specified by the ISO C standard, with the following exceptions:
a. An integer constant cannot begin with $0 x$ or include the hexadecimal digits ' $a^{\prime}$, ${ }^{\prime} b^{\prime}, c^{\prime}, d^{\prime}, e^{\prime} f^{\prime},^{\prime} A^{\prime}, B^{\prime}, C^{\prime}, D^{\prime}, E^{\prime}$, or ${ }^{\prime} F^{\prime}$ 。
b. The value of an integer constant beginning with 0 shall be taken in decimal rather than octal.
c. An integer constant cannot include a suffix ('u', 'U', ' $l^{\prime}$, or ${ }^{\prime} L^{\prime}$ ).
d. A floating constant cannot include a suffix ( $\mathrm{f}^{\prime}, \mathrm{I}^{\prime} \mathrm{F}^{\prime},^{\prime} \mathrm{l}^{\prime}$, or ${ }^{\prime} \mathrm{L}^{\prime}$ ).

If the value is too large or too small to be representable (see Section 1.7.2 (on page 7)), the behavior is undefined.
9. A sequence of underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set), beginning with an underscore or alphabetic, shall be considered a word.
10. The following words are keywords that shall be recognized as individual tokens; the name of the token is the same as the keyword:

| BEGIN | delete | END | function | in | printf |
| :--- | :--- | :--- | :--- | :--- | :--- |
| break | do | exit | getline | next | return |
| continue | else | for | if | print | while |

11. The following words are names of built-in functions and shall be recognized as the token BUILTIN_FUNC_NAME:

| atan2 | gsub | log | split | sub | toupper |
| :--- | :--- | :--- | :--- | :--- | :--- |
| close | index | match | sprintf | substr |  |
| cos | int | rand | sqrt | system |  |
| exp | length | sin | srand | tolower |  |

The above-listed keywords and names of built-in functions are considered reserved words.
12. The token NAME shall consist of a word that is not a keyword or a name of a built-in function and is not followed immediately (without any delimiters) by the ' (' character.
13. The token FUNC_NAME shall consist of a word that is not a keyword or a name of a built-in function, followed immediately (without any delimiters) by the ' (' character. The ' (' character shall not be included as part of the token.
14. The following two-character sequences shall be recognized as the named tokens:

| Token Name | Sequence | Token Name | Sequence |
| :--- | :---: | :--- | :---: |
| ADD_ASSIGN | $+=$ | NO_MATCH | $!\sim$ |
| SUB_ASSIGN | $-=$ | EQ | $==$ |
| MUL_ASSIGN | $\star=$ | LE | $<=$ |
| DIV_ASSIGN | $/=$ | GE | $>=$ |
| MOD_ASSIGN | $\%=$ | NE | $!=$ |
| POW_ASSIGN | $=$ | INCR | ++ |
| OR | $\mid$ | DECR | -- |
| AND | $\& \&$ | APPEND | $\gg$ |

15. The following single characters shall be recognized as tokens whose names are the character:
```
<newline> { } ( ) [ ] , ; + * % ^ ! > < ? : ~ $ =
```

There is a lexical ambiguity between the token ERE and the tokens $' /{ }^{\prime}$ and DIV_ASSIGN. When an input sequence begins with a slash character in any syntactic context where the token '/' or DIV_ASSIGN could appear as the next token in a valid program, the longer of those two tokens that can be recognized shall be recognized. In any other syntactic context where the token ERE could appear as the next token in a valid program, the token ERE shall be recognized.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were processed successfully.
$>0$ An error occurred.
The exit status can be altered within the program by using an exit expression.

## CONSEQUENCES OF ERRORS

If any file operand is specified and the named file cannot be accessed, awk shall write a diagnostic message to standard error and terminate without any further action.
If the program specified by either the program operand or a progfile operand is not a valid awk program (as specified in the EXTENDED DESCRIPTION section), the behavior is undefined.

## APPLICATION USAGE

The index, length, match, and substr functions should not be confused with similar functions in the ISO C standard; the awk versions deal with characters, while the ISO C standard deals with bytes.

Because the concatenation operation is represented by adjacent expressions rather than an explicit operator, it is often necessary to use parentheses to enforce the proper evaluation precedence.

## EXAMPLES

The awk program specified in the command line is most easily specified within single-quotes (for example, 'program') for applications using sh, because awk programs commonly contain characters that are special to the shell, including double-quotes. In the cases where an awk program contains single-quote characters, it is usually easiest to specify most of the program as strings within single-quotes concatenated by the shell with quoted single-quote characters. For example:

```
awk '/'\''/ { print "quote:", $0 }'
```

prints all lines from the standard input containing a single-quote character, prefixed with quote:. The following are examples of simple awk programs:

1. Write to the standard output all input lines for which field 3 is greater than 5 :
```
$3 > 5
```

2. Write every tenth line:
```
(NR % 10) == 0
```

3. Write any line with a substring matching the regular expression:

$$
/(G \mid D)\left(2[0-9][[: \text { alpha: }]]^{\star} /\right.
$$

4. Print any line with a substring containing a ${ }^{\prime} G^{\prime}$ or $D^{\prime}$, followed by a sequence of digits and characters. This example uses character classes digit and alpha to match languageindependent digit and alphabetic characters respectively:
(G|D) ([[:digit:][:alpha:] ] *)/
5. Write any line in which the second field matches the regular expression and the fourth field does not:
$\$ 2$ ~ $/ x y z /$ \&\& $\$ 4$ ! ~ $/ x y z /$
6. Write any line in which the second field contains a backslash:
```
$2 ~ /\\/
```

7. Write any line in which the second field contains a backslash. Note that backslash escapes are interpreted twice; once in lexical processing of the string and once in processing the regular expression:
```
$2 ~ "\\\\"
```

8. Write the second to the last and the last field in each line. Separate the fields by a colon: \{OFS=":";print \$(NF-1), \$NF \}
9. Write the line number and number of fields in each line. The three strings representing the line number, the colon, and the number of fields are concatenated and that string is written to standard output:
```
{print NR ":" NF}
```

10. Write lines longer than 72 characters:
```
length($0) > 72
```

11. Write the first two fields in opposite order separated by OFS:
```
{ print $2, $1 }
```

12. Same, with input fields separated by a comma or <space>s and <tab>s, or both:
```
BEGIN { FS = ",[ \t]*|[ \t]+" }
    { print $2, $1 }
```

13. Add up the first column, print sum, and average:
```
{s += $1 }
    {print "sum is ", s, " average is", s/NR}
```

14. Write fields in reverse order, one per line (many lines out for each line in):
```
{ for (i = NF; i > 0; --i) print $i }
```

15. Write all lines between occurrences of the strings start and stop:
```
/start/, /stop/
```

16. Write all lines whose first field is different from the previous one:
```
$1 != prev { print; prev = $1 }
```

17. Simulate echo:
```
BEGIN {
    for (i = 1; i < ARGC; ++i)
    printf("%s%s", ARGV[i], i==ARGC-1?"\n":" ")
}
```

18. Write the path prefixes contained in the PATH environment variable, one per line:
```
BEGIN {
    n = split (ENVIRON["PATH"], path, ":")
    for (i = 1; i <= n; ++i)
    print path[i]
}
```

19. If there is a file named input containing page headers of the form:

Page \#
and a file named program that contains:
/Page/ $\quad\{\$ 2=n++;\}$
\{ print \}
then the command line:
awk -f program n=5 input
prints the file input, filling in page numbers starting at 5 .

## RATIONALE

This description is based on the new awk, "nawk", (see the referenced The AWK Programming Language), which introduced a number of new features to the historical awk:

1. New keywords: delete, do, function, return
2. New built-in functions: atan2, close, cos, gsub, match, rand, sin, srand, sub, system
3. New predefined variables: FNR, ARGC, ARGV, RSTART, RLENGTH, SUBSEP
4. New expression operators: ?, :,,,,
5. The FS variable and the third argument to split, now treated as extended regular expressions.
6. The operator precedence, changed to more closely match the C language. Two examples of code that operate differently are:
```
while ( n /= 10 > 1) ...
if (!"wk" ~ /bwk/) ...
```

Several features have been added based on newer implementations of $a w k$ :

- Multiple instances of $-\mathbf{f}$ progfile are permitted.
- The new option -v assignment.
- The new predefined variable ENVIRON.
- New built-in functions toupper and tolower.
- More formatting capabilities are added to printf to match the ISO C standard.

The overall awk syntax has always been based on the C language, with a few features from the shell command language and other sources. Because of this, it is not completely compatible with any other language, which has caused confusion for some users. It is not the intent of the standard developers to address such issues. A few relatively minor changes toward making the language more compatible with the ISO C standard were made; most of these changes are based on similar changes in recent implementations, as described above. There remain several Clanguage conventions that are not in awk. One of the notable ones is the comma operator, which is commonly used to specify multiple expressions in the C language for statement. Also, there are various places where awk is more restrictive than the C language regarding the type of expression that can be used in a given context. These limitations are due to the different features that the $a w k$ language does provide.

Regular expressions in azok have been extended somewhat from historical implementations to make them a pure superset of extended regular expressions, as defined by IEEE Std 1003.1-200x (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions). The main extensions are internationalization features and interval expressions. Historical implementations of awk have long supported backslash escape sequences as an extension to extended regular expressions, and this extension has been retained despite inconsistency with other utilities. The number of escape sequences recognized in both extended regular expressions and strings has varied (generally increasing with time) among implementations. The set specified by IEEE Std 1003.1-200x includes most sequences known to be supported by popular implementations and by the ISO C standard. One sequence that is not supported is hexadecimal value escapes beginning with ' $\backslash \mathrm{x}$ '. This would allow values expressed in more than 9 bits to be used within awk as in the ISO C standard. However, because this syntax has a non-deterministic length, it does not permit the subsequent character to be a hexadecimal digit. This limitation can be dealt with in the C language by the use of lexical string concatenation. In the awk language, concatenation could also be a solution for strings, but not for extended regular expressions (either lexical ERE tokens or strings used dynamically as regular expressions). Because of this limitation, the feature has not been added to IEEE Std 1003.1-200x.
When a string variable is used in a context where an extended regular expression normally appears (where the lexical token ERE is used in the grammar) the string does not contain the literal slashes.
Some versions of $a w k$ allow the form:
func name (args, ... ) \{ statements \}
This has been deprecated by the authors of the language, who asked that it not be specified.
Historical implementations of $a w k$ produce an error if a next statement is executed in a BEGIN action, and cause awk to terminate if a next statement is executed in an END action. This behavior has not been documented, and it was not believed that it was necessary to standardize it.

The specification of conversions between string and numeric values is much more detailed than in the documentation of historical implementations or in the referenced The AWK Programming Language. Although most of the behavior is designed to be intuitive, the details are necessary to ensure compatible behavior from different implementations. This is especially important in relational expressions since the types of the operands determine whether a string or numeric comparison is performed. From the perspective of an application writer, it is usually sufficient to expect intuitive behavior and to force conversions (by adding zero or concatenating a null string) when the type of an expression does not obviously match what is needed. The intent has been to specify historical practice in almost all cases. The one exception is that, in historical implementations, variables and constants maintain both string and numeric values after their original value is converted by any use. This means that referencing a variable or constant can have unexpected side effects. For example, with historical implementations the following program:
\{

$$
\begin{aligned}
& a="+2 " \\
& b=2 \\
& \text { if (NR } \% 2) \\
& \quad c=a+b \\
& \text { if ( } a==b \text { ) } \\
& \text { print "numeric comparison" } \\
& \text { else } \\
& \quad \text { print "string comparison" }
\end{aligned}
$$

\}
would perform a numeric comparison (and output numeric comparison) for each oddnumbered line, but perform a string comparison (and output string comparison) for each evennumbered line. IEEE Std 1003.1-200x ensures that comparisons will be numeric if necessary. With historical implementations, the following program:

```
BEGIN {
    OFMT = "%e"
    print 3.14
    OFMT = "%f"
    print 3.14
}
```

would output " $3.140000 \mathrm{e}+00$ " twice, because in the second print statement the constant " 3.14 " would have a string value from the previous conversion. IEEE Std 1003.1-200x requires that the output of the second print statement be " 3.140000 ". The behavior of historical implementations was seen as too unintuitive and unpredictable.
It was pointed out that with the rules contained in early drafts, the following script would print nothing:

```
BEGIN {
    y[1.5] = 1
    OFMT = "%e"
    print y[1.5]
}
```

Therefore, a new variable, CONVFMT, was introduced. The OFMT variable is now restricted to affecting output conversions of numbers to strings and CONVFMT is used for internal conversions, such as comparisons or array indexing. The default value is the same as that for OFMT, so unless a program changes CONVFMT (which no historical program would do), it will receive the historical behavior associated with internal string conversions.

The POSIX awk lexical and syntactic conventions are specified more formally than in other sources. Again the intent has been to specify historical practice. One convention that may not be obvious from the formal grammar as in other verbal descriptions is where <newline>s are acceptable. There are several obvious placements such as terminating a statement, and a backslash can be used to escape <newline>s between any lexical tokens. In addition, <newline>s without backslashes can follow a comma, an open brace, a logical AND operator ("\&\&"), a logical OR operator ( $"|\mid "$ ), the do keyword, the else keyword, and the closing parenthesis of an if, for, or while statement. For example:

```
{ print $1,
```

        \$2 \}
    The requirement that awk add a trailing <newline> to the program argument text is to simplify the grammar, making it match a text file in form. There is no way for an application or test suite to determine whether a literal <newline> is added or whether awk simply acts as if it did.

IEEE Std 1003.1-200x requires several changes from historical implementations in order to support internationalization. Probably the most subtle of these is the use of the decimal-point character, defined by the LC_NUMERIC category of the locale, in representations of floatingpoint numbers. This locale-specific character is used in recognizing numeric input, in converting between strings and numeric values, and in formatting output. However, regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimalpoint character recognized in processing awk programs (including assignments in command line arguments). This is essentially the same convention as the one used in the ISO C standard. The difference is that the $C$ language includes the setlocale() function, which permits an application to modify its locale. Because of this capability, a C application begins executing with its locale set to the C locale, and only executes in the environment-specified locale after an explicit call to setlocale(). However, adding such an elaborate new feature to the awk language was seen as inappropriate for IEEE Std 1003.1-200x. It is possible to execute an awk program explicitly in any desired locale by setting the environment in the shell.
The undefined behavior resulting from NULs in extended regular expressions allows future extensions for the GNU gawk program to process binary data.
The behavior in the case of invalid awk programs (including lexical, syntactic, and semantic errors) is undefined because it was considered overly limiting on implementations to specify. In most cases such errors can be expected to produce a diagnostic and a non-zero exit status. However, some implementations may choose to extend the language in ways that make use of certain invalid constructs. Other invalid constructs might be deemed worthy of a warning, but otherwise cause some reasonable behavior. Still other constructs may be very difficult to detect in some implementations. Also, different implementations might detect a given error during an initial parsing of the program (before reading any input files) while others might detect it when executing the program after reading some input. Implementors should be aware that diagnosing errors as early as possible and producing useful diagnostics can ease debugging of applications, and thus make an implementation more usable.
The unspecified behavior from using multi-character RS values is to allow possible future extensions based on extended regular expressions used for record separators. Historical implementations take the first character of the string and ignore the others.
Unspecified behavior when split(string,array, <null>) is used is to allow a proposed future extension that would split up a string into an array of individual characters.

In the context of the getline function, equally good arguments for different precedences of the I and < operators can be made. Historical practice has been that:

```
getline < "a" "b"
is parsed as:
```

```
( getline < "a" ) "b"
```

```
( getline < "a" ) "b"
```

although many would argue that the intent was that the file ab should be read. However:

```
getline < "x" + 1
```

parses as:
getline < ( "x" + 1 )
Similar problems occur with the I version of getline, particularly in combination with $\$$. For example:

```
$"echo hi" | getline
```

(This situation is particularly problematic when used in a print statement, where the I getline part might be a redirection of the print.)
Since in most cases such constructs are not (or at least should not) be used (because they have a natural ambiguity for which there is no conventional parsing), the meaning of these constructs has been made explicitly unspecified. (The effect is that a conforming application that runs into the problem must parenthesize to resolve the ambiguity.) There appeared to be few if any actual uses of such constructs.
Grammars can be written that would cause an error under these circumstances. Where backwards-compatibility is not a large consideration, implementors may wish to use such grammars.
Some historical implementations have allowed some built-in functions to be called without an argument list, the result being a default argument list chosen in some "reasonable" way. Use of length as a synonym for length $(\$ 0)$ is the only one of these forms that is thought to be widely known or widely used; this particular form is documented in yarious places (for example, most historical awk reference pages, although not in the referenced The AWK Programming Language) as legitimate practice. With this exception, default argument lists have always been undocumented and vaguely defined, and it is not at all clear how (or if) they should be generalized to userdefined functions. They add no useful functionality and preclude possible future extensions that might need to name functions without calling them. Not standardizing them seems the simplest course. The standard developers considered that length merited special treatment, however, since it has been documented in the past and sees possibly substantial use in historical programs. Accordingly, this usage has been made legitimate, but Issue 5 removed the obsolescent marking for XSI-conforming implementations and many otherwise conforming applications depend on this feature.
In sub and gsub, if repl is a string literal (the lexical token STRING), then two consecutive backslash characters should be used in the string to ensure a single backslash will precede the ampersand when the resultant string is passed to the function. (For example, to specify one literal ampersand in the replacement string, use gsub(ERE, " $\backslash \backslash \& ")$ ).
Historically the only special character in the repl argument of sub and gsub string functions was the ampersand $\left({ }^{\prime} \delta^{\prime}\right)$ character and preceding it with the backslash character was used to turn off its special meaning.
The description in the ISO POSIX-2: 1993 standard introduced behavior such that the backslash character was another special character and it was unspecified whether there were any other special characters. This description introduced several portability problems, some of which are
described below, and so it has been replaced with the more historical description. Some of the problems include:

- Historically, to create the replacement string, a script could use gsub(ERE, " $\backslash \backslash \&$ "), but with the ISO POSIX-2: 1993 standard wording, it was necessary to use gsub(ERE, " $\backslash \backslash \backslash \backslash \& ")$. Backslash characters are doubled here because all string literals are subject to lexical analysis, which would reduce each pair of backslash characters to a single backslash before being passed to gsub.
- Since it was unspecified what the special characters were, for portable scripts to guarantee that characters are printed literally, each character had to be preceded with a backslash. (For example, a portable script had to use gsub(ERE, " $\backslash \backslash h \backslash \backslash i "$ ) to produce a replacement string of "hi".)
The description for comparisons in the ISO POSIX-2: 1993 standard did not properly describe historical practice because of the way numeric strings are compared as numbers. The current rules cause the following code:

```
if (0 == "000")
    print "strange, but true"
else
    print "not true"
```

to do a numeric comparison, causing the if to succeed. It should be intuitively obvious that this is incorrect behavior, and indeed, no historical implementation of awk actually behaves this way.

To fix this problem, the definition of numeric string was enhanced to include only those values obtained from specific circumstances (mostly external sources) where it is not possible to determine unambiguously whether the value is intended to be a string or a numeric.
Variables that are assigned to a numeric string shall also be treated as a numeric string. (For example, the notion of a numeric string can be propagated across assignments.) In comparisons, all variables having the uninitialized value are to be treated as a numeric operand evaluating to the numeric value zero.

Uninitialized variables include all types of variables including scalars, array elements, and fields. The definition of an uninitialized value in Variables and Special Variables is necessary to describe the value placed on uninitialized variables and on fields that are valid (for example, < $\$ N F)$ but have no characters in them and to describe how these variables are to be used in comparisons. A valid field, such as $\mathbf{\$ 1}$, that has no characters in it can be obtained from an input line of " $\backslash t \backslash t$ " when $\mathbf{F S}==^{\prime} \backslash t^{\prime}$. Historically, the comparison ( $\$ \mathbf{1 < 1 0}$ ) was done numerically after evaluating $\$ 1$ to the value zero.
The phrase "... also shall have the numeric value of the numeric string" was removed from several sections of the ISO POSIX-2: 1993 standard because is specifies an unnecessary implementation detail. It is not necessary for IEEE Std 1003.1-200x to specify that these objects be assigned two different values. It is only necessary to specify that these objects may evaluate to two different values depending on context.

The description of numeric string processing is based on the behavior of the atof() function in the ISO C standard. While it is not a requirement for an implementation to use this function, many historical implementations of awk do. In the ISO C standard, floating-point constants use a period as a decimal point character for the language itself, independent of the current locale, but the $\operatorname{atof}()$ function and the associated strtod() function use the decimal point character of the current locale when converting strings to numeric values. Similarly in awk, floating-point constants in an awk script use a period independent of the locale, but input strings use the decimal point character of the locale.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
The awk utility is aligned with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE PASC Interpretation 1003.2 \#211 is applied, adding the sentence "An occurrence of two consecutive backslashes shall be interpreted as just a single literal backslash character." into the description of the sub string function.

Issue 7
PASC Interpretation 1003.2-1992 \#107 (SD5-XCU-ERN-73) is applied, updating the description of the OFS variable.
SD5-XCU-ERN-79 is applied, restoring the horizontal lines to Table 4-1 (on page 156), and SD5-XCU-ERN-80 is applied, changing the order of some table entries.
SD5-XCU-ERN-87 is applied, updating the descriptive text of the Grammar.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
basename - return non-directory portion of a pathname

## SYNOPSIS

```
basename string [suffix]
```

## DESCRIPTION

The string operand shall be treated as a pathname, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.266, Pathname. The string string shall be converted to the filename corresponding to the last pathname component in string and then the suffix string suffix, if present, shall be removed. This shall be done by performing actions equivalent to the following steps in order:

1. If string is a null string, it is unspecified whether the resulting string is ' ${ }^{\prime}$ or a null string. In either case, skip steps 2 through 6.
2. If string is "//", it is implementation-defined whether steps 3 to 6 are skipped or processed.
3. If string consists entirely of slash characters, string shall be set to a single slash character. In this case, skip steps 4 to 6 .
4. If there are any trailing slash characters in string, they shall be removed.
5. If there are any slash characters remaining in string, the prefix of string up to and including the last slash character in string shall be removed.
6. If the suffix operand is present, is not identical to the characters remaining in string, and is identical to a suffix of the characters remaining in string, the suffix suffix shall be removed from string. Otherwise, string is not modified by this step. It shall not be considered an error if suffix is not found in string.
The resulting string shall be written to standard output.

## OPTIONS

None.

## OPERANDS

The following operands shall be supported:

$$
\begin{array}{ll}
\text { string } & \text { A string. } \\
\text { suffix } & \text { A string. }
\end{array}
$$

## STDIN

Not used.

## INPUT FILES

## None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of basename:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The basename utility shall write a line to the standard output in the following format:

```
"%s\n", <resulting string>
```

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The definition of pathname specifies implementation-defined behavior for pathnames starting with two slash characters. Therefore, applications shall not arbitrarily add slashes to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

## EXAMPLES

If the string string is a valid pathname:
\$(basename "string")
produces a filename that could be used to open the file named by string in the directory returned by:

```
$(dirname "string")
```

If the string string is not a valid pathname, the same algorithm is used, but the result need not be a valid filename. The basename utility is not expected to make any judgements about the validity of string as a pathname; it just follows the specified algorithm to produce a result string.
The following shell script compiles /usr/src/cmd/cat.c and moves the output to a file named cat in the current directory when invoked with the argument/usr/src/cmd/cat or with the argument /usr/src/cmd/cat.c:

```
c99 $(dirname "$1")/$(basename "$1" . c).c
mv a.out $(basename "$1" .c)
```

## RATIONALE

The behaviors of basename and dirname have been coordinated so that when string is a valid pathname:

```
$(basename "string")
```

would be a valid filename for the file in the directory:

```
$(dirname "string")
```

This would not work for the early proposal versions of these utilities due to the way it specified handling of trailing slashes.

Since the definition of pathname specifies implementation-defined behavior for pathnames starting with two slash characters, this volume of IEEE Std 1003.1-200x specifies similar implementation-defined behavior for the basename and dirname utilities.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.5 (on page 33), dirname

## CHANGE HISTORY

First released in Issue 2.
Issue 6
IEEE PASC Interpretation 1003.2 \#164 is applied.
The normative text is reworded to avoid use of the term "must" for application requirements.

NAME
batch - schedule commands to be executed in a batch queue

## SYNOPSIS

```
batch
```

## DESCRIPTION

The batch utility shall read commands from standard input and schedule them for execution in a batch queue. It shall be the equivalent of the command:
at -q b -m now
where queue $b$ is a special at queue, specifically for batch jobs. Batch jobs shall be submitted to the batch queue with no time constraints and shall be run by the system using algorithms, based on unspecified factors, that may vary with each invocation of batch.
xSI Users shall be permitted to use batch if their name appears in the file at.allow which is located in an implementation-defined directory. If that file does not exist, the file at.deny, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to batch. If neither file exists, only a process with the appropriate privileges shall be allowed to submit a job. If only at.deny exists and is empty, global usage shall be permitted. The at.allow and at.deny files shall consist of one user name per line.

## OPTIONS

None.
OPERANDS
None.

## STDIN

The standard input shall be a text file consisting of commands acceptable to the shell command language described in Chapter 2 (on page 29).

## INPUT FILES

xsi The text files at.allow and at.deny, which are located in an implementation-defined directory, shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the at and batch utilities.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of batch:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

```
LC_TIME Determine the format and contents for date and time strings written by batch.
xsi
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
SHELL Determine the name of a command interpreter to be used to invoke the at-job. If the variable is unset or null, sh shall be used. If it is set to a value other than a name for sh, the implementation shall do one of the following: use that shell; use sh; use the login shell from the user database; any of the preceding accompanied by a warning diagnostic about which was chosen.
TZ Determine the timezone. The job shall be submitted for execution at the time specified by timespec or \(-\mathbf{t}\) time relative to the timezone specified by the \(T Z\) variable. If timespec specifies a timezone, it overrides TZ. If timespec does not specify a timezone and \(T Z\) is unset or null, an unspecified default timezone shall be used.
```

## ASYNCHRONOUS EVENTS

```
Default.
```

## STDOUT

```
When standard input is a terminal, prompts of unspecified format for each line of the user input described in the STDIN section may be written to standard output.
```

## STDERR

```
The following shall be written to standard error when a job has been successfully submitted:
"job \%s at \%s\n", at_job_id, <date>
where date shall be equivalent in format to the output of:
```

```
date +"%a %b %e %T %Y"
```

date +"%a %b %e %T %Y"
The date and time written shall be adjusted so that they appear in the timezone of the user (as determined by the $T Z$ variable).
Neither this, nor warning messages concerning the selection of the command interpreter, are considered a diagnostic that changes the exit status.
Diagnostic messages, if any, shall be written to standard error.

```

\section*{OUTPUT FILES}
```

None.

```

\section*{EXTENDED DESCRIPTION}
```

None.

```

\section*{EXIT STATUS}
```

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

```

\section*{CONSEQUENCES OF ERRORS}
```

The job shall not be scheduled.

```

\section*{APPLICATION USAGE}

It may be useful to redirect standard output within the specified commands.

\section*{EXAMPLES}
1. This sequence can be used at a terminal:
```

batch
sort < file >outfile
EOT

```
2. This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):
```

batch <<
! diff file1 file2 2>\&1 >outfile | mailx mygroup
!

```

\section*{RATIONALE}

Early proposals described batch in a manner totally separated from at, even though the historical model treated it almost as a synonym for \(a t-\mathbf{q b}\). A number of features were added to list and control batch work separately from those in at. Upon further reflection, it was decided that the benefit of this did not merit the change to the historical interface.

The \(-\mathbf{m}\) option was included on the equivalent at command because it is historical practice to mail results to the submitter, even if all job-produced output is redirected. As explained in the RATIONALE for \(a t\), the now keyword submits the job for immediate execution (after scheduling delays), despite some historical systems where at now would have been considered an error.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO
at

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The NAME is changed to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.

\section*{Issue 7}

The batch utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the batch utility.

NAME
bc - arbitrary-precision arithmetic language

\section*{SYNOPSIS}

> bc [-l] [file...]

\section*{DESCRIPTION}

The \(b c\) utility shall implement an arbitrary precision calculator. It shall take input from any files given, then read from the standard input. If the standard input and standard output to \(b c\) are attached to a terminal, the invocation of \(b c\) shall be considered to be interactive, causing behavioral constraints described in the following sections.

\section*{OPTIONS}

The \(b c\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following option shall be supported:
-1 (The letter ell.) Define the math functions and initialize scale to 20, instead of the default zero; see the EXTENDED DESCRIPTION section.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a text file containing bc program statements. After all files have been read, \(b c\) shall read the standard input.

\section*{STDIN}

See the INPUT FILES section.

\section*{INPUT FILES}

Input files shall be text files containing a sequence of comments, statements, and function definitions that shall be executed as they are read.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(b c\) :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The output of the \(b c\) utility shall be controlled by the program read, and consist of zero or more lines containing the value of all executed expressions without assignments. The radix and precision of the output shall be controlled by the values of the obase and scale variables; see the EXTENDED DESCRIPTION section.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

\section*{Grammar}

The grammar in this section and the lexical conventions in the following section shall together describe the syntax for \(b c\) programs. The general conventions for this style of grammar are described in Section 1.10 (on page 18). A valid program can be represented as the non-terminal symbol program in the grammar. This formal syntax shall take precedence over the text syntax description.

The lexical conventions for bc programs, with respect to the preceding grammar, shall be as follows:
1. Except as noted, bc shall recognize the longest possible token or delimiter beginning at a given point.
2. A comment shall consist of any characters beginning with the two adjacent characters " /*" and terminated by the next occurrence of the two adjacent characters "*/". Comments shall have no effect except to delimit lexical tokens.
3. The <newline> shall be recognized as the token NEWLINE.
4. The token STRING shall represent a string constant; it shall consist of any characters beginning with the double-quote character ( \({ }^{\prime \prime}\) ') and terminated by another occurrence of the double-quote character. The value of the string is the sequence of all characters between, but not including, the two double-quote characters. All characters shall be taken literally from the input, and there is no way to specify a string containing a double-quote character. The length of the value of each string shall be limited to \{BC_STRING_MAX\} bytes.
5. A <blank> shall have no effect except as an ordinary character if it appears within a STRING token, or to delimit a lexical token other than STRING.
6. The combination of a backslash character immediately followed by a <newline> shall have no effect other than to delimit lexical tokens with the following exceptions:
- It shall be interpreted as the character sequence " \(\backslash<\) newline>" in STRING tokens.
- It shall be ignored as part of a multi-line NUMBER token.
7. The token NUMBER shall represent a numeric constant. It shall be recognized by the following grammar:
```

NUMBER : integer
'.' integer
integer '.'
integer '.' integer
;
integer : digit
| integer digit
;

```

```

    ;
    ```
8. The value of a NUMBER token shall be interpreted as a numeral in the base specified by the value of the internal register ibase (described below). Each of the digit characters shall have the value from 0 to 15 in the order listed here, and the period character shall represent the radix point. The behavior is undefined if digits greater than or equal to the value of ibase appear in the token. However, note the exception for single-digit values being assigned to ibase and obase themselves, in Operations in bc (on page 197).
9. The following keywords shall be recognized as tokens:
\begin{tabular}{lllll} 
auto & ibase & length & return & while \\
break & if & obase & scale & \\
define & for & quit & sqrt &
\end{tabular}
10. Any of the following characters occurring anywhere except within a keyword shall be recognized as the token LETTER:

11. The following single-character and two-character sequences shall be recognized as the token ASSIGN_OP:

12. If an ' \(=\) ' character, as the beginning of a token, is followed by a '_' character with no intervening delimiter, the behavior is undefined.
13. The following single-characters shall be recognized as the token MUL_OP:
* / \%
14. The following single-character and two-character sequences shall be recognized as the token REL_OP:
== <= >= != < >
15. The following two-character sequences shall be recognized as the token INCR_DECR:
++ --
16. The following single characters shall be recognized as tokens whose names are the character:
```

<newline> ( ) , + - ; [ ] ^ { }

```
17. The token EOF is returned when the end of input is reached.

\section*{Operations in bc}

There are three kinds of identifiers: ordinary identifiers, array identifiers, and function identifiers. All three types consist of single lowercase letters. Array identifiers shall be followed by square brackets ("[]"). An array subscript is required except in an argument or auto list. Arrays are singly dimensioned and can contain up to \(\left\{B C \_D I M \_M A X\right\}\) elements. Indexing shall begin at zero so an array is indexed from 0 to \(\left\{B C \_D I M \_M A X\right\}-1\). Subscripts shall be truncated to integers. The application shall ensure that function identifiers are followed by parentheses, possibly enclosing arguments. The three types of identifiers do not conflict.
The following table summarizes the rules for precedence and associativity of all operators. Operators on the same line shall have the same precedence; rows are in order of decreasing precedence.

Table 4-3 Operators in bc
\begin{tabular}{|c|c|}
\hline Operator & Associativity \\
\hline ++, -- & N/A \\
\hline unary - & N/A \\
\hline ^ & Right to left \\
\hline *, /, \% & Left to right \\
\hline +, binary - & Left to right \\
\hline , \(+=,-=, *=, ~ /=, ~ \%=\) & Right to left \\
\hline \[
==,<=,>=, \quad!=,<,
\] & None \\
\hline
\end{tabular}

Each expression or named expression has a scale, which is the number of decimal digits that shall be maintained as the fractional portion of the expression.
Named expressions are places where values are stored. Named expressions shall be valid on the left side of an assignment. The value of a named expression shall be the value stored in the place named. Simple identifiers and array elements are named expressions; they have an initial value of zero and an initial scale of zero.
The internal registers scale, ibase, and obase are all named expressions. The scale of an expression consisting of the name of one of these registers shall be zero; values assigned to any of these registers are truncated to integers. The scale register shall contain a global value used in computing the scale of expressions (as described below). The value of the register scale is limited to \(0 \leq\) scale \(\leq\left\{B C \_S C A L E \_M A X\right\}\) and shall have a default value of zero. The ibase and obase registers are the input and output number radix, respectively. The value of ibase shall be limited to:
```

2 < ibase \leq 16

```

The value of obase shall be limited to:
```

2 < obase \leq {BC_BASE_MAX}

```

When either ibase or obase is assigned a single digit value from the list in Lexical Conventions in bc (on page 195), the value shall be assumed in hexadecimal. (For example, ibase \(=\mathrm{A}\) sets to base ten, regardless of the current ibase value.) Otherwise, the behavior is undefined when digits greater than or equal to the value of ibase appear in the input. Both ibase and obase shall have initial values of 10 .

Internal computations shall be conducted as if in decimal, regardless of the input and output bases, to the specified number of decimal digits. When an exact result is not achieved (for example, scale \(=0 ; 3.2 / 1\) ), the result shall be truncated.

For all values of obase specified by this volume of IEEE Std 1003.1-200x, bc shall output numeric values by performing each of the following steps in order:
1. If the value is less than zero, a hyphen ( \({ }^{\prime}-^{\prime}\) ) character shall be output.
2. One of the following is output, depending on the numerical value:
- If the absolute value of the numerical value is greater than or equal to one, the integer portion of the value shall be output as a series of digits appropriate to obase (as described below), most significant digit first. The most significant non-zero digit shall be output next, followed by each successively less significant digit.
- If the absolute value of the numerical value is less than one but greater than zero and the scale of the numerical value is greater than zero, it is unspecified whether the character 0 is output.
- If the numerical value is zero, the character 0 shall be output.
3. If the scale of the value is greater than zero and the numeric value is not zero, a period character shall be output, followed by a series of digits appropriate to obase (as described below) representing the most significant portion of the fractional part of the value. If \(s\) represents the scale of the value being output, the number of digits output shall be \(s\) if obase is 10 , less than or equal to \(s\) if obase is greater than 10, or greater than or equal to \(s\) if obase is less than 10 . For obase values other than 10, this should be the number of digits needed to represent a precision of \(10^{5}\).
For obase values from 2 to 16, valid digits are the first obase of the single characters:
\(\begin{array}{lllllllllllllllll}0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & A & B & C & D & E & F\end{array}\)
which represent the values zero to 15 , inclusive, respectively.
For bases greater than 16, each digit shall be written as a separate multi-digit decimal number. Each digit except the most significant fractional digit shall be preceded by a single <space>. For bases from 17 to \(100, b c\) shall write two-digit decimal numbers; for bases from 101 to 1000 , threedigit decimal strings, and so on. For example, the decimal number 1024 in base 25 would be written as:
\(\Delta 01 \Delta 15 \Delta 24\)
and in base 125 , as:
\(\Delta 008 \Delta 024\)
Very large numbers shall be split across lines with 70 characters per line in the POSIX locale; other locales may split at different character boundaries. Lines that are continued shall end with a backslash ( \({ }^{\prime} \backslash \prime\) ).
A function call shall consist of a function name followed by parentheses containing a commaseparated list of expressions, which are the function arguments. A whole array passed as an argument shall be specified by the array name followed by empty square brackets. All function arguments shall be passed by value. As a result, changes made to the formal parameters shall have no effect on the actual arguments. If the function terminates by executing a return statement, the value of the function shall be the value of the expression in the parentheses of the return statement or shall be zero if no expression is provided or if there is no return statement.
The result of sqrt(expression) shall be the square root of the expression. The result shall be truncated in the least significant decimal place. The scale of the result shall be the scale of the expression or the value of scale, whichever is larger.
The result of length(expression) shall be the total number of significant decimal digits in the expression. The scale of the result shall be zero.

The result of scale(expression) shall be the scale of the expression. The scale of the result shall be zero.

A numeric constant shall be an expression. The scale shall be the number of digits that follow the radix point in the input representing the constant, or zero if no radix point appears.

The sequence (expression ) shall be an expression with the same value and scale as expression. The parentheses can be used to alter the normal precedence.

The semantics of the unary and binary operators are as follows:

\section*{-expression}

The result shall be the negative of the expression. The scale of the result shall be the scale of expression.
The unary increment and decrement operators shall not modify the scale of the named expression upon which they operate. The scale of the result shall be the scale of that named expression.
++named-expression
The named expression shall be incremented by one. The result shall be the value of the named expression after incrementing.
--named-expression
The named expression shall be decremented by one. The result shall be the value of the named expression after decrementing.
named-expression++
The named expression shall be incremented by one. The result shall be the value of the named expression before incrementing.
named-expression--
The named expression shall be decremented by one. The result shall be the value of the named expression before decrementing.
The exponentiation operator, circumflex \((\sim)\), shall bind right to left.

\section*{expression^expression}

The result shall be the first expression raised to the power of the second expression. If the second expression is not an integer, the behavior is undefined. If \(a\) is the scale of the left expression and \(b\) is the absolute value of the right expression, the scale of the result shall be:
if \(b>=0 \min (a * b, \max (s c a l e, a))\) if \(b<0\) scale
The multiplicative operators \(\left(\prime^{\prime *}, \prime \prime \prime \prime \%\right.\) ) shall bind left to right.
expression*expression
The result shall be the product of the two expressions. If \(a\) and \(b\) are the scales of the two expressions, then the scale of the result shall be:
```

    min(a+b,max(scale, a,b))
    ```
expression/expression
The result shall be the quotient of the two expressions. The scale of the result shall be the value of scale.
expression\%expression
For expressions \(a\) and \(b, a \% b\) shall be evaluated equivalent to the steps:
1. Compute \(a / b\) to current scale.
2. Use the result to compute:
\[
\mathrm{a}-(\mathrm{a} / \mathrm{b}) * \mathrm{~b}
\]
to scale:
```

max(scale + scale(b), scale(a))

```

The scale of the result shall be:
```

max(scale + scale(b), scale(a))

```

When scale is zero, the \({ }^{\prime} \% \prime\) operator is the mathematical remainder operator.
The additive operators ( \({ }^{\prime}+^{\prime},{ }^{\prime}-^{\prime}\) ) shall bind left to right.
expression+expression
The result shall be the sum of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.
expression-expression
The result shall be the difference of the two expressions. The scale of the result shall be the maximum of the scales of the expressions.
The assignment operators ( \(\quad=\prime\), "+=", "-=", "*=", "/=", "\%=", " ^=") shall bind right to left. named-expression=expression

This expression shall result in assigning the value of the expression on the right to the named expression on the left. The scale of both the named expression and the result shall be the scale of expression.
The compound assignment forms:
named-expression <operator>= expression
shall be equivalent to:
named-expression=named-expression <operator> expression
except that the named-expression shall be evaluated only once.
Unlike all other operators, the relational operators ( \(\ll\), < only valid as the object of an if, while, or inside a for statement.
expression1<expression2
The relation shall be true if the value of expression1 is strictly less than the value of expression2.
expression1>expression 2
The relation shall be true if the value of expression1 is strictly greater than the value of expression2.
expression \(1<=\) expression 2
The relation shall be true if the value of expression 1 is less than or equal to the value of expression2.
expression1>=expression 2
The relation shall be true if the value of expression1 is greater than or equal to the value of expression 2.
expression \(1==\) expression 2
The relation shall be true if the values of expression 1 and expression 2 are equal.
expression1!=expression 2
The relation shall be true if the values of expression1 and expression 2 are unequal.
There are only two storage classes in bc: global and automatic (local). Only identifiers that are local to a function need be declared with the auto command. The arguments to a function shall be local to the function. All other identifiers are assumed to be global and available to all
functions. All identifiers, global and local, have initial values of zero. Identifiers declared as auto shall be allocated on entry to the function and released on returning from the function. They therefore do not retain values between function calls. Auto arrays shall be specified by the array name followed by empty square brackets. On entry to a function, the old values of the names that appear as parameters and as automatic variables shall be pushed onto a stack. Until the function returns, reference to these names shall refer only to the new values.

References to any of these names from other functions that are called from this function also refer to the new value until one of those functions uses the same name for a local variable.

When a statement is an expression, unless the main operator is an assignment, execution of the statement shall write the value of the expression followed by a <newline>.

When a statement is a string, execution of the statement shall write the value of the string.
Statements separated by semicolons or <newline>s shall be executed sequentially. In an interactive invocation of \(b c\), each time a <newline> is read that satisfies the grammatical production:
input_item : semicolon_list NEWLINE
the sequential list of statements making up the semicolon_list shall be executed immediately and any output produced by that execution shall be written without any delay due to buffering.

In an if statement (if(relation) statement), the statement shall be executed if the relation is true.
The while statement (while(relation) statement) implements a loop in which the relation is tested; each time the relation is true, the statement shall be executed and the relation retested. When the relation is false, execution shall resume after statement.
A for statement(for(expression; relation; expression) statement) shall be the same as:
first-expression
while (relation)
statement
last-expression
\}
The application shall ensure that all three expressions are present.
The break statement shall cause termination of a for or while statement.
The auto statement (auto identifier [,identifier] ...) shall cause the values of the identifiers to be pushed down. The identifiers can be ordinary identifiers or array identifiers. Array identifiers shall be specified by following the array name by empty square brackets. The application shall ensure that the auto statement is the first statement in a function definition.
A define statement:
define LETTER ( opt_parameter_list ) \{
opt_auto_define_list
statement_list
\}
defines a function named LETTER. If a function named LETTER was previously defined, the define statement shall replace the previous definition. The expression:

LETTER ( opt_argument_list )
shall invoke the function named LETTER. The behavior is undefined if the number of arguments in the invocation does not match the number of parameters in the definition. Functions shall be defined before they are invoked. A function shall be considered to be defined within its own body, so recursive calls are valid. The values of numeric constants within a
function shall be interpreted in the base specified by the value of the ibase register when the function is invoked.
The return statements (return and return(expression)) shall cause termination of a function, popping of its auto variables, and specification of the result of the function. The first form shall be equivalent to return(0). The value and scale of the result returned by the function shall be the value and scale of the expression returned.

The quit statement (quit) shall stop execution of a \(b c\) program at the point where the statement occurs in the input, even if it occurs in a function definition, or in an if, for, or while statement.
The following functions shall be defined when the -1 option is specified:
s(expression)
Sine of argument in radians.
c( expression )
Cosine of argument in radians.
a( expression)
Arctangent of argument.
1( expression )
Natural logarithm of argument.
e( expression )
Exponential function of argument.
j( expression, expression)
Bessel function of integer order.

The scale of the result returned by these functions shall be the value of the scale register at the time the function is invoked. The value of the scale register after these functions have completed their execution shall be the same value it had upon invocation. The behavior is undefined if any of these functions is invoked with an argument outside the domain of the mathematical function.

\section*{EXIT STATUS}

The following exit values shall be returned:
0
All input files were processed successfully.
unspecified
An error occurred.

\section*{CONSEQUENCES OF ERRORS}

If any file operand is specified and the named file cannot be accessed, \(b c\) shall write a diagnostic message to standard error and terminate without any further action.
In an interactive invocation of \(b c\), the utility should print an error message and recover following any error in the input. In a non-interactive invocation of \(b c\), invalid input causes undefined behavior.

\section*{APPLICATION USAGE}

Automatic variables in \(b c\) do not work in exactly the same way as in either C or PL/1.
For historical reasons, the exit status from \(b c\) cannot be relied upon to indicate that an error has occurred. Returning zero after an error is possible. Therefore, \(b c\) should be used primarily by interactive users (who can react to error messages) or by application programs that can somehow validate the answers returned as not including error messages.
The \(b c\) utility always uses the period ( \({ }^{\prime} . \prime\) ) character to represent a radix point, regardless of any decimal-point character specified as part of the current locale. In languages like C or awk, the period character is used in program source, so it can be portable and unambiguous, while the
locale-specific character is used in input and output. Because there is no distinction between source and input in \(b c\), this arrangement would not be possible. Using the locale-specific character in \(b c^{\prime}\) s input would introduce ambiguities into the language; consider the following example in a locale with a comma as the decimal-point character:
```

define f(a,b) {
}
...
f(1,2,3)

```

Because of such ambiguities, the period character is used in input. Having input follow different conventions from output would be confusing in either pipeline usage or interactive usage, so the period is also used in output.

\section*{EXAMPLES}

In the shell, the following assigns an approximation of the first ten digits of ' \(\pi^{\prime}\) to the variable \(x\) :
```

x=\$(printf "%s\n" 'scale = 10; 104348/33215' | bc)

```

The following \(b c\) program prints the same approximation of \(' \pi^{\prime}\), with a label, to standard output:
```

scale = 10
"pi equals "
104348 / 33215

```

The following defines a function to compute an approximate value of the exponential function (note that such a function is predefined if the -1 option is specified):
```

scale = 20
define e(x){
auto a, b, c, i, s
a = 1
b=1
s = 1
for (i = 1; 1 == 1; i++){
a=a*x
b=b*i
c=a/b
if (c == 0) {
return(s)
}
s = s+c
}
}

```

The following prints approximate values of the exponential function of the first ten integers:
```

for (i = 1; i <= 10; ++i) {
e(i)
}

```

\section*{RATIONALE}

The \(b c\) utility is implemented historically as a front-end processor for \(d c\); \(d c\) was not selected to be part of this volume of IEEE Std 1003.1-200x because \(b c\) was thought to have a more intuitive programmatic interface. Current implementations that implement \(b c\) using \(d c\) are expected to be compliant.
The exit status for error conditions has been left unspecified for several reasons:
- The \(b c\) utility is used in both interactive and non-interactive situations. Different exit codes may be appropriate for the two uses.
- It is unclear when a non-zero exit should be given; divide-by-zero, undefined functions, and syntax errors are all possibilities.
- It is not clear what utility the exit status has.
- In the 4.3 BSD, System V, and Ninth Edition implementations, \(b c\) works in conjunction with \(d c\). The \(d c\) utility is the parent, \(b c\) is the child. This was done to cleanly terminate \(b c\) if \(d c\) aborted.

The decision to have \(b c\) exit upon encountering an inaccessible input file is based on the belief that \(b c\) file1 file2 is used most often when at least file1 contains data/function declarations/initializations. Having \(b c\) continue with prerequisite files missing is probably not useful. There is no implication in the CONSEQUENCES OF ERRORS section that bc must check all its files for accessibility before opening any of them.
There was considerable debate on the appropriateness of the language accepted by bc. Several reviewers preferred to see either a pure subset of the \(C\) language or some changes to make the language more compatible with \(C\). While the \(b c\) language has some obvious similarities to \(C\), it has never claimed to be compatible with any version of \(C\). An interpreter for a subset of \(C\) might be a very worthwhile utility, and it could potentially make bc obsolete. However, no such utility is known in historical practice, and it was not within the scope of this volume of IEEE Std 1003.1-200x to define such a language and utility. If and when they are defined, it may be appropriate to include them in a future version of IEEE Std 1003.1. This left the following alternatives:
1. Exclude any calculator language from this volume of IEEE Std 1003.1-200x.

The consensus of the standard developers was that a simple programmatic calculator language is very useful for both applications and interactive users. The only arguments for excluding any calculator were that it would become obsolete if and when a Ccompatible one emerged, or that the absence would encourage the development of such a C-compatible one. These arguments did not sufficiently address the needs of current application writers.
2. Standardize the historical \(d c\), possibly with minor modifications.

The consensus of the standard developers was that \(d c\) is a fundamentally less usable language and that that would be far too severe a penalty for avoiding the issue of being similar to but incompatible with \(C\).
3. Standardize the historical \(b c\), possibly with minor modifications.

This was the approach taken. Most of the proponents of changing the language would not have been satisfied until most or all of the incompatibilities with \(C\) were resolved. Since most of the changes considered most desirable would break historical applications and require significant modification to historical implementations, almost no modifications were made. The one significant modification that was made was the replacement of the historical \(b c\) assignment operators " \(=+\) ", and so on, with the more modern " \(+=\) ", and so on. The older versions are considered to be fundamentally flawed because of the lexical ambiguity in uses like \(a=-1\).

In order to permit implementations to deal with backwards-compatibility as they see fit, the behavior of this one ambiguous construct was made undefined. (At least three implementations have been known to support this change already, so the degree of change involved should not be great.)
The \({ }^{\prime} \%\) ' operator is the mathematical remainder operator when scale is zero. The behavior of this operator for other values of scale is from historical implementations of \(b c\), and has been
maintained for the sake of historical applications despite its non-intuitive nature.
Historical implementations permit setting ibase and obase to a broader range of values. This includes values less than 2, which were not seen as sufficiently useful to standardize. These implementations do not interpret input properly for values of ibase that are greater than 16. This is because numeric constants are recognized syntactically, rather than lexically, as described in this volume of IEEE Std 1003.1-200x. They are built from lexical tokens of single hexadecimal digits and periods. Since <blank>s between tokens are not visible at the syntactic level, it is not possible to recognize the multi-digit "digits" used in the higher bases properly. The ability to recognize input in these bases was not considered useful enough to require modifying these implementations. Note that the recognition of numeric constants at the syntactic level is not a problem with conformance to this volume of IEEE Std 1003.1-200x, as it does not impact the behavior of conforming applications (and correct \(b c\) programs). Historical implementations also accept input with all of the digits \(0^{\prime} 0^{\prime} 9^{\prime}\) and \({ }^{\prime} A^{\prime}-^{\prime} F^{\prime}\) regardless of the value of ibase; since digits with value greater than or equal to ibase are not really appropriate, the behavior when they appear is undefined, except for the common case of:
```

ibase=8;
/* Process in octal base. */
ibase=A
/* Restore decimal base. *//

```

In some historical implementations, if the expression to be written is an uninitialized array element, a leading <space> and/or up to four leading 0 characters may be output before the character zero. This behavior is considered a bug; it is unlikely that any currently conforming application relies on:
echo 'b[3]' | bc
returning 00000 rather than 0 .
Exact calculation of the number of fractional digits to output for a given value in a base other than 10 can be computationally expensive. Historical implementations use a faster approximation, and this is permitted. Note that the requirements apply only to values of obase that this volume of IEEE Std 1003.1-200x requires implementations to support (in particular, not to 1,0 , or negative bases, if an implementation supports them as an extension).

Historical implementations of bc did not allow array parameters to be passed as the last parameter to a function. New implementations are encouraged to remove this restriction even though it is not required by the grammar.

\hline
\end{tabular}

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

The output of \(b g\) shall consist of a line in the format:
" [\%d] \%s\n", <job-number>, <command>
where the fields are as follows:
<job-number> A number that can be used to identify the job to the wait, fg, and kill utilities. Using these utilities, the job can be identified by prefixing the job number with \(\prime\) ' \(\circ\) '.
<command> The associated command that was given to the shell.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

\section*{CONSEQUENCES OF ERRORS}

If job control is disabled, the bg utility shall exit with an error and no job shall be placed in the background.

\section*{APPLICATION USAGE}

A job is generally suspended by typing the SUSP character (<control>-Z on most systems); see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. At that point, \(b g\) can put the job into the background. This is most effective when the job is expecting no terminal input and its output has been redirected to non-terminal files. A background job can be forced to stop when it has terminal output by issuing the command:
stty tostop
A background job can be stopped with the command:
```

kill -s stop job ID

```

The \(b g\) utility does not work as expected when it is operating in its own utility execution environment because that environment has no suspended jobs. In the following examples:
... | xargs bg
(bg)
each \(b g\) operates in a different environment and does not share its parent shell's understanding of jobs. For this reason, \(b g\) is generally implemented as a shell regular built-in.

\section*{EXAMPLES}

\section*{None.}

\section*{RATIONALE}

The extensions to the shell specified in this volume of IEEE Std 1003.1-200x have mostly been based on features provided by the KornShell. The job control features provided by bg, fg, and jobs are also based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the

C shell, the KornShell versions were selected for this volume of IEEE Std 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).
The \(b g\) utility is expected to wrap its output if the output exceeds the number of display columns.

\section*{FUTURE DIRECTIONS}

SEE ALSO
Section 2.9.3.1 (on page 50), \(f g\), kill, jobs, wait

\section*{CHANGE HISTORY}

This utility is marked as part of the User Portability Utilities option.
The JC margin marker on the SYNOPSIS is removed since support for Job Control is mandatory in this issue. This is a FIPS requirement.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

\section*{None.}

\section*{First released in Issue 4.}

\section*{Issue 6}

\section*{Issue 7}

NAME
c99 - compile standard C programs

\section*{SYNOPSIS}

CD c99 [-c] [-D name[=value]]... [-E] [-g] [-I directory]... [-L directory]... [-o outfile] [-O optlevel] [-s] [-U name]... operand...

\section*{DESCRIPTION}

The c99 utility is an interface to the standard C compilation system; it shall accept source code conforming to the ISO C standard. The system conceptually consists of a compiler and link editor. The files referenced by operands shall be compiled and linked to produce an executable file. (It is unspecified whether the linking occurs entirely within the operation of c99; some implementations may produce objects that are not fully resolved until the file is executed.)
If the -c option is specified, for all pathname operands of the form file.c, the files:
\$(basename pathname .c).o
shall be created as the result of successful compilation. If the -c option is not specified, it is unspecified whether such .o files are created or deleted for the file.c operands.

If there are no options that prevent link editing (such as -c or \(-\mathbf{E}\) ), and all operands compile and link without error, the resulting executable file shall be written according to the \(-\mathbf{o}\) outfile option (if present) or to the file a.out.
The executable file shall be created as specified in Section 1.7.1.4 (on page 4), except that the file permission bits shall be set to:
S_IRWXO | S_IRWXG | S_IRWXU
and the bits specified by the umask of the process shall be cleared.

\section*{OPTIONS}

The c99 utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that:
- The - library operands have the format of options, but their position within a list of operands affects the order in which libraries are searched.
- The order of specifying the \(-\mathbf{I}\) and \(-\mathbf{L}\) options is significant.

Options can be interspersed with operands.
- Conforming applications shall specify each option separately; that is, grouping option letters (for example, \(-\mathbf{c O}\) ) need not be recognized by all implementations.
The following options shall be supported:
-c Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.
-g Produce symbolic information in the object or executable files; the nature of this information is unspecified, and may be modified by implementation-defined interactions with other options.
-s Produce object or executable files, or both, from which symbolic and other information not required for proper execution using the exec family defined in the System Interfaces volume of IEEE Std 1003.1-200x has been removed (stripped). If both \(-\mathbf{g}\) and \(-\mathbf{s}\) options are present, the action taken is unspecified.
-o outfile Use the pathname outfile, instead of the default a.out, for the executable file produced. If the \(-\mathbf{o}\) option is present with \(-\mathbf{c}\) or \(-\mathbf{E}\), the result is unspecified.
-D name[=value]
Define name as if by a C-language \#define directive. If no =value is given, a value of 1 shall be used. The \(-\mathbf{D}\) option has lower precedence than the \(-\mathbf{U}\) option. That is, if name is used in both \(\mathbf{a}-\mathbf{U}\) and \(\mathbf{a}-\mathbf{D}\) option, name shall be undefined regardless of the order of the options. Additional implementation-defined names may be provided by the compiler. Implementations shall support at least 2048 bytes of -D definitions and 256 names.
-E Copy C-language source files to standard output, expanding all preprocessor directives; no compilation shall be performed. If any operand is not a text file, the effects are unspecified.
-I directory Change the algorithm for searching for headers whose names are not absolute pathnames to look in the directory named by the directory pathname before looking in the usual places. Thus, headers whose names are enclosed in double-quotes (" ") shall be searched for first in the directory of the file with the \#include line, then in directories named in \(-\mathbf{I}\) options, and last in the usual places. For headers whose names are enclosed in angle brackets ("<>"), the header shall be searched for only in directories named in -I options and then in the usual places. Directories named in -I options shall be searched in the order specified. Implementations shall support at least ten instances of this option in a single c99 command invocation.
\(-\mathbf{L}\) directory Change the algorithm of searching for the libraries named in the \(-\mathbf{l}\) objects to look in the directory named by the directory pathname before looking in the usual places. Directories named in \(-\mathbf{L}\) options shall be searched in the order specified. Implementations shall support at least ten instances of this option in a single c99 command invocation. If a directory specified by a \(-\mathbf{L}\) option contains files with names starting with any of the strings "libc.", "libl.", "libpthread.", "libm." "librt.", "libtrace.", "libxnet.", or "liby.", the results are unspecified.
-O optlevel Specify the level of code optimization. If the optlevel option-argument is the digit ' 0 ', all special code optimizations shall be disabled. If it is the digit ' 1 ', the nature of the optimization is unspecified. If the \(-\mathbf{O}\) option is omitted, the nature of the system's default optimization is unspecified. It is unspecified whether code generated in the presence of the \(-\mathbf{O} 0\) option is the same as that generated when - \(\mathbf{O}\) is omitted. Other optlevel values may be supported.
-U name Remove any initial definition of name.
Multiple instances of the \(-\mathbf{D},-\mathbf{I},-\mathbf{U}\), and \(-\mathbf{L}\) options can be specified.

\section*{OPERANDS}

An operand is either in the form of a pathname or the form -library, or is one of two consecutive operands of the form \(-\mathbf{1}\) for the first and library for the second. The application shall ensure that at least one operand of the pathname form is specified. The following operands shall be supported:
file.c A C-language source file to be compiled and optionally linked. The application shall ensure that the operand is of this form if the -c option is used.
file.a A library of object files typically produced by the ar utility, and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than .a as denoting object file libraries.
8329
8330
file. \(\mathbf{o}\)
An object file produced by c99 -c and passed directly to the link editor. Implementations may recognize implementation-defined suffixes other than . \(\mathbf{o}\) as denoting object files.
The processing of other files is implementation-defined.
\begin{tabular}{ll}
-1 library & (A hyphen, the letter ell, and a library name.) \\
-1 library & (Two consecutive operands, the first being a hyphen and the letter ell; the second \\
being a library name.) \\
& Search the library named: \\
& liblibrary. a
\end{tabular}

For the remainder of this description of the c99 utility, both of the forms - library and -lilibrary are referred to as the -1 operand for brevity (even though the - library form is actually two operands).

A library shall be searched when its name is encountered, so the placement of a \(-\mathbf{1}\) operand is significant. Several standard libraries can be specified in this manner, as described in the EXTENDED DESCRIPTION section. Implementations may recognize implementation-defined suffixes other than .a as denoting libraries.

If the last operand is a -1 with no library name, then the c99 utility shall write a diagnostic message to standard error and shall return a non-zero exit status.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

The input file shall be one of the following: a text file containing a C-language source program, an object file in the format produced by c99-c, or a library of object files, in the format produced by archiving zero or more object files, using ar. Implementations may supply additional utilities that produce files in these formats. Additional input file formats are implementation-defined.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of c99:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

If more than one file operand ending in .c (or possibly other unspecified suffixes) is given, for each such file:
```

"%s:\n", <file>

```
may be written. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard output if they are written to the standard error, as described in the STDERR section.

If the -E option is specified, the standard output shall be a text file that represents the results of the preprocessing stage of the language; it may contain extra information appropriate for subsequent compilation passes.

\section*{STDERR}

The standard error shall be used only for diagnostic messages. If more than one file operand ending in .c (or possibly other unspecified suffixes) is given, for each such file:
```

"%s:\n", <file>

```
may be written to allow identification of the diagnostic and warning messages with the appropriate input file. These messages, if written, shall precede the processing of each input file; they shall not be written to the standard error if they are written to the standard output, as described in the STDOUT section.
This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

\section*{OUTPUT FILES}

Object files or executable files or both are produced in unspecified formats. If an existing file that does not resolve to a regular file matches the name of an object file being written or matches the name of an executable file being created by c99, it is unspecified whether c99 shall attempt to write the object file or create the executable file, or shall issue a diagnostic and exit with a nonzero exit status.

\section*{EXTENDED DESCRIPTION}

Standard Libraries
The \(c 99\) utility shall recognize the following \(-\mathbf{1}\) operands for standard libraries:
-1 c This operand shall make visible all functions referenced in the System Interfaces volume of IEEE Std 1003.1-200x, with the possible exception of those functions listed as residing in <aio.h>, <arpa/inet.h>, <complex.h>, <fenv.h>, <math.h>, <mqueue.h>, <netdb.h>, <net/if.h>, <netinet/in.h>, <pthread.h>, <sched.h>, <semaphore.h>, <spawn.h>, <sys/socket.h>, pthread_kill(), and pthread_sigmask() in <signal.h>, <trace.h>, functions marked as optional in <sys/mman.h>, functions marked as ADV (Advisory Information) in <fentl.h>, and functions beginning with the prefix clock_ or time_ in <time.h>. This operand shall not be required to be present to cause a search of this library.
-11 This operand shall make visible all functions required by the C-language output of lex that are not made available through the -1 c operand.
-l pthread This operand shall make visible all functions referenced in <pthread.h> and pthread_kill() and pthread_sigmask() referenced in <signal.h>. An implementation may search this library in the absence of this operand.

This operand shall make visible all functions referenced in <math.h>, <complex.h>, and <fenv.h>. An implementation may search this library in the absence of this operand.
This operand shall make visible all functions referenced in <aio.h>, <mqueue.h>, <sched.h>, <semaphore.h>, and <spawn.h>, functions marked as optional in <sys/mman.h>, functions marked as ADV (Advisory Information) in <fentl.h>, and functions beginning with the prefix clock_ and time_ in <time.h>. An implementation may search this library in the absence of this operand.
This operand shall make visible all functions referenced in <trace.h>. An implementation may search this library in the absence of this operand.

In the absence of options that inhibit invocation of the link editor, such as -c or -E, the c99 utility shall cause the equivalent of a -1 c operand to be passed to the link editor as the last -1 operand, causing it to be searched after all other object files and libraries are loaded.

It is unspecified whether the libraries libc.a, libm.a, librt.a, libpthread.a, libl.a, liby.a, or libxnet.a exist as regular files. The implementation may accept as -1 operands names of objects that do not exist as regular files.

\section*{External Symbols}

The C compiler and link editor shall support the significance of external symbols up to a length of at least 31 bytes; the action taken upon encountering symbols exceeding the implementationdefined maximum symbol length is unspecified.
The compiler and link editor shall support a minimum of 511 external symbols per source or object file, and a minimum of 4095 external symbols in total. A diagnostic message shall be written to the standard output if the implementation-defined limit is exceeded; other actions are unspecified.

\section*{Programming Environments}

All implementations shall support one of the following programming environments as a default. Implementations may support more than one of the following programming environments. Applications can use sysconf() or getconf to determine which programming environments are supported.

Table 4-4 Programming Environments: Type Sizes
\begin{tabular}{|l|c|c|c|c|}
\hline \begin{tabular}{c} 
Programming Environment \\
getconf Name
\end{tabular} & \begin{tabular}{c} 
Bits in \\
int
\end{tabular} & \begin{tabular}{c} 
Bits in \\
long
\end{tabular} & \begin{tabular}{c} 
Bits in \\
pointer
\end{tabular} & \begin{tabular}{c} 
Bits in \\
off_t
\end{tabular} \\
\hline -POSIX_V7_ILP32_OFF32 & 32 & 32 & 32 & 32 \\
-POSIX_V7_ILP32_OFFBIG & 32 & 32 & 32 & \(\geq 64\) \\
-POSIX_V7_LP64_OFF64 & 32 & 64 & 64 & 64 \\
_POSIX_V7_LPBIG_OFFBIG & \(\geq 32\) & \(\geq 64\) & \(\geq 64\) & \(\geq 64\) \\
\hline
\end{tabular}

All implementations shall support one or more environments where the widths of the following types are no greater than the width of type long:
blksize_t, cc_t, mode_t, nfds_t, pid_t, ptrdiff_t, size_t, speed_t, ssize_t, suseconds_t, tcflag_t, wchar_t, wint_t

The executable files created when these environments are selected shall be in a proper format for execution by the exec family of functions. Each environment may be one of the ones in Table 4-4 (on page 215), or it may be another environment. The names for the environments that meet this requirement shall be output by a getconf command using the POSIX_V7_WIDTH_RESTRICTED_ENVS argument, as a <newline>-separated list of names suitable for use with the getconf \(-\mathbf{v}\) option. If more than one environment meets the requirement, the names of all such environments shall be output on separate lines. Any of these names can then be used in a subsequent getconf command to obtain the flags specific to that environment with the following suffixes added as appropriate:
_CFLAGS To get the C compiler flags.
_LDFLAGS To get the linker/loader flags.
_LIBS To get the libraries.
This requirement may be removed in a future version.
When this utility processes a file containing a function called main(), it shall be defined with a return type equivalent to int. Using return from the initial call to main() shall be equivalent (other than with respect to language scope issues) to calling exit() with the returned value. Reaching the end of the initial call to main() shall be equivalent to calling exit(0). The implementation shall not declare a prototype for this function.
Implementations provide configuration strings for \(C\) compiler flags, linker/loader flags, and libraries for each supported environment. When an application needs to use a specific programming environment rather than the implementation default programming environment while compiling, the application shall first verify that the implementation supports the desired environment. If the desired programming environment is supported, the application shall then invoke c99 with the appropriate C compiler flags as the first options for the compile, the appropriate linker/loader flags after any other options but before any operands, and the appropriate libraries at the end of the operands.
Conforming applications shall not attempt to link together object files compiled for different programming models. Applications shall also be aware that binary data placed in shared memory or in files might not be recognized by applications built for other programming models.

Table 4-5 Programming Environments: \(c 99\) and \(c c\) Arguments
\begin{tabular}{|c|c|c|}
\hline Programming Environment getconf Name & Use & c99 and cc Arguments getconf Name \\

& \text { POSIX_V7_LPBIG_OFFBIG_LIBS }
\end{aligned}
\] \\
\hline
\end{tabular}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful compilation or link edit.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

When c99 encounters a compilation error that causes an object file not to be created, it shall write a diagnostic to standard error and continue to compile other source code operands, but it shall not perform the link phase and return a non-zero exit status. If the link edit is unsuccessful, a diagnostic message shall be written to standard error and c99 exits with a non-zero status. A conforming application shall rely on the exit status of \(c 99\), rather than on the existence or mode of the executable file.

\section*{APPLICATION USAGE}

Since the c99 utility usually creates files in the current directory during the compilation process, it is typically necessary to run the c99 utility in a directory in which a file can be created.
On systems providing POSIX Conformance (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 2, Conformance), c99 is required only with the C-Language Development option; XSI-conformant systems always provide c99.
Some historical implementations have created .o files when -c is not specified and more than one source file is given. Since this area is left unspecified, the application cannot rely on. \(\boldsymbol{o}\) files being created, but it also must be prepared for any related .o files that already exist being deleted at the completion of the link edit.
Some historical implementations have permitted \(-\mathbf{L}\) options to be interspersed with \(-\mathbf{1}\) operands on the command line. For an application to compile consistently on systems that do not behave like this, it is necessary for a conforming application to supply all -L options before any of the \(-\mathbf{1}\) options.
There is the possible implication that if a user supplies versions of the standard functions (before they would be encountered by an implicit \(-1 \mathbf{c}\) or explicit \(-\mathbf{l m}\) ), that those versions would be used in place of the standard versions. There are various reasons this might not be true (functions defined as macros, manipulations for clean name space, and so on), so the existence of files named in the same manner as the standard libraries within the \(-\mathbf{L}\) directories is explicitly stated to produce unspecified behavior.

All of the functions specified in the System Interfaces volume of IEEE Std 1003.1-200x may be made visible by implementations when the Standard C Library is searched. Conforming applications must explicitly request searching the other standard libraries when functions made visible by those libraries are used.

\section*{EXAMPLES}
1. The following usage example compiles foo.c and creates the executable file foo:
```

c99 -o foo foo.c

```

The following usage example compiles foo.c and creates the object file foo.o:
c99 - C foo.c
The following usage example compiles foo.c and creates the executable file a.out:
c99 foo.c
The following usage example compiles foo.c, links it with bar.o, and creates the executable file a.out. It may also create and leave foo.o:
```

c99 foo.c bar.o

```
2. The following example shows how an application using threads interfaces can test for support of and use a programming environment supporting 32-bit int, long, and pointer types and an off_t type using at least 64 bits:
```

if [ \$(getconf _POSIX_V7_ILP32_OFFBIG) != "-1" ]
then
c99 \$(getconf POSIX_V7_ILP32_OFFBIG_CFLAGS) -D_XOPEN_SOURCE=700
\$(getconf POSIX_V7_ILP32_OFFBIG_LDFLAGS) foo.c -o foo \
\$(getconf POSIX_V7_ILP32_OFFBIG_LIBS) -1 pthread
else
echo ILP32_OFFBIG programming environment not supported
exit 1
fi

```
3. The following examples clarify the use and interactions of \(-\mathbf{L}\) options and -1 operands.

Consider the case in which module a.c calls function \(f()\) in library libQ.a, and module b.c calls function \(g()\) in library libp.a. Assume that both libraries reside in \(/ \mathbf{a} / \mathbf{b} / \mathbf{c}\). The command line to compile and link in the desired way is:
c99-L \(\langle a / b / c\) main.o a.c -1 e b.c -1 p
In this case the \(-L\) operand need only precede the first -1 operand, since both libQ.a and libp.a reside in the same directory.
Multiple -L operands can be used when library name collisions occur. Building on the previous example, suppose that the user wants to use a new libp.a, in /a/a/a, but still wants \(f()\) from \(/ \mathbf{a} / \mathrm{b} / \mathrm{c} / \mathrm{libQ} . \mathrm{a}:\)
```

c99 -L /a/a/a -L /a/b/c main.o a.c -l Q b.c -l p

```

In this example, the linker searches the -L options in the order specified, and finds \(/ \mathbf{a} / \mathbf{a} / \mathbf{a} / \mathrm{libp} . \mathbf{a}\) before \(/ \mathbf{a} / \mathbf{b} / \mathbf{c} / \mathrm{libp} . a\) when resolving references for \(\mathbf{b} . \mathbf{c}\). The order of the \(-\mathbf{l}\) operands is still important, however.
4. The following example shows how an application can use a programming environment where the widths of the following types:
blksize_t, cc_t, mode_t, nfds_t, pid_t, ptrdiff_t, size_t, speed_t, ssize_t, suseconds_t, tcflag_t, wchar_t, wint_t
are no greater than the width of type long:

\section*{RATIONALE} standard. operand, and the \(-\mathbf{1}\) trace operand added for the Tracing functions. regular files or symbolic links that point to regular files.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO} Chapter 13, Headers

\section*{CHANGE HISTORY} the c99 math headers.
```

# First choose one of the listed environments ...

# ... if there are no additional constraints, the first one will do:

CENV=\$(getconf POSIX_V7_WIDTH_RESTRICTED_ENVS | head -n l)

# ... or, if an environment that supports large files is preferred,

# look for names that contain "OFF64" or "OFFBIG". (This chooses

# the last one in the list if none match.)

for CENV in \$(getconf POSIX_V7_WIDTH_RESTRICTED_ENVS)
do
case \$CENV in
*OFF64*|*OFFBIG*) break ; ;
esac
done

# The chosen environment name can now be used like this:

c99 \$(getconf \${CENV}_CFLAGS) -D _POSIX_C_SOURCE=200xxxL \
\$(getconf \${CENV}_LDFLAGS) foo.c -o foo \
\$(getconf \${CENV}_LIBS)

```

The c99 utility is based on the c89 utility originally introduced in the ISO POSIX-2:1993

Some of the changes from \(c 89\) include the modification to the contents of the Standard Libraries section to account for new headers and options; for example, <spawn.h> added to the \(\mathbf{- 1 \mathbf { r t }}\)

This standard specifies that the c99 utility must be able to use regular files for *.o files and for a.out files. Implementations are free to overwrite existing files of other types when attempting to create object files and executable files, but are not required to do so. If something other than a regular file is specified and using it fails for any reason, c99 is required to issue a diagnostic message and exit with a non-zero exit status. But for some file types, the problem may not be noticed for a long time. For example, if a FIFO named a.out exists in the current directory, c99 may attempt to open a.out and will hang in the open() call until another process opens the FIFO for reading. Then 699 may write most of the a.out to the FIFO and fail when it tries to seek back close to the start of the file to insert a timestamp (FIFOs are not seekable files). The c99 utility is also allowed to issue a diagnostic immediately if it encounters an a.out or *.o file that is not a regular file. For portable use, applications should ensure that any a.out, \(-\mathbf{o}\) option-argument, or *.o files corresponding to any \({ }^{*} . \mathrm{c}\) files do not conflict with names already in use that are not

Section 1.7.1.4 (on page 4), ar, getconf, make, nm, strip, umask, the System Interfaces volume of IEEE Std 1003.1-200x, exec, sysconf(), the Base Definitions volume of IEEE Std 1003.1-200x,

NAME
cat - concatenate and print files

\section*{SYNOPSIS}
cat [-u] [file...]

DESCRIPTION
The cat utility shall read files in sequence and shall write their contents to the standard output in the same sequence.

\section*{OPTIONS}

The cat utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following option shall be supported:
\(-\mathbf{u} \quad\) Write bytes from the input file to the standard output without delay as each is read.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of an input file. If no file operands are specified, the standard input shall be used. If a file is \({ }^{\prime}-\quad\), the eat utility shall read from the standard input at that point in the sequence. The cat utility shall not close and reopen standard input when it is referenced in this way, but shall accept multiple occurrences of \({ }^{\prime} \mathbf{~}^{\prime}\) as a file operand.

\section*{STDIN}

The standard input shall be used only if no file operands are specified, or if a file operand is ' - '. See the INPUT FILES section.

\section*{INPUT FILES}

The input files can be any file type.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of cat:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

The standard output shall contain the sequence of bytes read from the input files. Nothing else shall be written to the standard output.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 All input files were output successfully.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

The \(-\mathbf{u}\) option has value in prototyping non-blocking reads from FIFOs. The intent is to support the following sequence:
```

mkfifo foo
cat -u foo > /dev/tty13 \&
cat -u > foo

```

It is unspecified whether standard output is or is not buffered in the default case. This is sometimes of interest when standard output is associated with a terminal, since buffering may delay the output. The presence of the \(-\mathbf{u}\) option guarantees that unbuffered I/O is available. It is implementation-defined whether the cat utility buffers output if the -u option is not specified. Traditionally, the \(-\mathbf{u}\) option is implemented using the equivalent of the setvbuf() function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

\section*{EXAMPLES}

The following command:
cat myfile
writes the contents of the file myfile to standard output.
The following command:
```

cat doc1 doc2 > doc.all

```
concatenates the files doc1 and doc2 and writes the result to doc.all.
Because of the shell language mechanism used to perform output redirection, a command such as this:
```

cat doc doc.end > doc

```
causes the original data in doc to be lost.
The command:
```

cat start - middle - end > file

```
when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a
single invocation of cat. Note, however, that if standard input is a regular file, this would be equivalent to the command:
```

cat start - middle /dev/null end > file

```
because the entire contents of the file would be consumed by cat the first time \({ }^{\prime}-^{\prime}\) was used as a file operand and an end-of-file condition would be detected immediately when ' -' was referenced the second time.

\section*{RATIONALE}

Historical versions of the cat utility include the options \(-\mathbf{e},-\mathbf{t}\), and \(-\mathbf{v}\), which permit the ends of lines, <tab>s, and invisible characters, respectively, to be rendered visible in the output. The standard developers omitted these options because they provide too fine a degree of control over what is made visible, and similar output can be obtained using a command such as:
```

sed -n -e 's/$/$/' -e l pathname

```

The -s option was omitted because it corresponds to different functions in BSD and System V-based systems. The BSD -s option to squeeze blank lines can be accomplished by the shell script shown in the following example:
```

sed -n '

```
\# Write non-empty lines.
/./ \{
    p
    d
    \}
\# Write a single empty line, then look for more empty lines.
/^\$/ p
\# Get next line, discard the held <newline> (empty line),
\# and look for more empty lines.
: Empty
/^\$/ \{
            N
        s/.//
        b Empty
    \}
\# Write the non-empty line before going back to search
\# for the first in a set of empty lines.
    p

The System V -s option to silence error messages can be accomplished by redirecting the standard error. Note that the BSD documentation for cat uses the term "blank line" to mean the same as the POSIX "empty line": a line consisting only of a <newline>.

The BSD -n option was omitted because similar functionality can be obtained from the \(-\mathbf{n}\) option of the pr utility.

\section*{CHANGE HISTORY}

First released in Issue 2.

NAME
cd - change the working directory

\section*{SYNOPSIS}
```

cd [-L|-P] [directory]
cd -

```

\section*{DESCRIPTION}

The \(c d\) utility shall change the working directory of the current shell execution environment (see Section 2.12 (on page 61)) by executing the following steps in sequence. (In the following steps, the symbol curpath represents an intermediate value used to simplify the description of the algorithm used by \(c d\). There is no requirement that curpath be made visible to the application.)
1. If no directory operand is given and the \(H O M E\) environment variable is empty or undefined, the default behavior is implementation-defined and no further steps shall be taken.
2. If no directory operand is given and the HOME environment variable is set to a non-empty value, the \(c d\) utility shall behave as if the directory named in the HOME environment variable was specified as the directory operand.
3. If the directory operand begins with a slash character, set curpath to the operand and proceed to step 7.
4. If the first component of the directory operand is dot or dot-dot, proceed to step 6.
5. Starting with the first pathname in the colon-separated pathnames of CDPATH (see the ENVIRONMENT VARIABLES section) if the pathname is non-null, test if the concatenation of that pathname, a slash character, and the directory operand names a directory. If the pathname is null, test if the concatenation of dot, a slash character, and the operand names a directory. In either case, if the resulting string names an existing directory, set curpath to that string and proceed to step 7 . Otherwise, repeat this step with the next pathname in CDPATH until all pathnames have been tested.
6. If the \(-\mathbf{P}\) option is in effect, set curpath to the directory operand. Otherwise, set curpath to the string formed by the concatenation of the value of \(P W D\), a slash character, and the operand.
7. If the \(-\mathbf{P}\) option is in effect, proceed to step 10. If curpath does not begin with a slash character, set curpath to the string formed by the concatenation of the value of \(P W D\), a slash character, and the operand.
8. The curpath value shall then be converted to canonical form as follows, considering each component from beginning to end, in sequence:
a. Dot components and any slashes that separate them from the next component shall be deleted.
b. For each dot-dot component, if there is a preceding component and it is neither root nor dot-dot, then:
i. If the preceding component does not refer (in the context of pathname resolution with symbolic links followed) to a directory, then the \(c d\) utility shall display an appropriate error message and no further steps shall be taken.
ii. The preceding component, all slashes separating the preceding component from dot-dot, dot-dot, and all slashes separating dot-dot from the following component (if any) shall be deleted.
c. An implementation may further simplify curpath by removing any trailing slash characters that are not also leading slashes, replacing multiple non-leading consecutive slashes with a single slash, and replacing three or more leading slashes with a single slash. If, as a result of this canonicalization, the curpath variable is null, no further steps shall be taken.
9. If curpath is longer than \{PATH_MAX\} bytes (including the terminating null) and the directory operand was not longer than \(\left\{\mathrm{PATH} \_\mathrm{MAX}\right\}\) bytes (including the terminating null), then curpath shall be converted from an absolute pathname to an equivalent relative pathname if possible. This conversion shall always be considered possible if the value of \(P W D\), with a trailing slash added if it does not already have one, is an initial substring of curpath. Whether or not it is considered possible under other circumstances is unspecified. Implementations may also apply this conversion if curpath is not longer than \(\left\{\mathrm{PATH} \_\mathrm{MAX}\right\}\) bytes or the directory operand was longer than \(\{\mathrm{PATH}\) _MAX \(\}\) bytes.
10. The \(c d\) utility shall then perform actions equivalent to the chdir() function called with curpath as the path argument. If these actions fail for any reason, the \(c d\) utility shall display an appropriate error message and the remainder of this step shall not be executed. If the \(\mathbf{- P}\) option is not in effect, the \(P W D\) environment variable shall be set to the value that curpath had on entry to step 9 (i.e., before conversion to a relative pathname). If the \(-\mathbf{P}\) option is in effect, the \(P W D\) environment variable shall be set to an absolute pathname for the current working directory and shall not contain filename components that, in the context of pathname resolution, refer to a file of type symbolic link. If there is insufficient permission on the new directory, or on any parent of that directory, to determine the current working directory, the value of the \(P W D\) environment variable is unspecified.
If, during the execution of the above steps, the \(P W D\) environment variable is changed, the OLDPWD environment variable shall also be changed to the value of the old working directory (that is the current working directory immediately prior to the call to \(c d\) ).

\section*{OPTIONS}

The \(c d\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported by the implementation:
-L Handle the operand dot-dot logically; symbolic link components shall not be resolved before dot-dot components are processed (see steps 8. and 9. in the DESCRIPTION).
-P Handle the operand dot-dot physically; symbolic link components shall be resolved before dot-dot components are processed (see step 7. in the DESCRIPTION).

If both \(-\mathbf{L}\) and \(-\mathbf{P}\) options are specified, the last of these options shall be used and all others ignored. If neither \(-\mathbf{L}\) nor \(-\mathbf{P}\) is specified, the operand shall be handled dot-dot logically; see the DESCRIPTION.

\section*{OPERANDS}

The following operands shall be supported:
directory An absolute or relative pathname of the directory that shall become the new working directory. The interpretation of a relative pathname by \(c d\) depends on the -L option and the CDPATH and PWD environment variables. If directory is an empty string, the results are unspecified.

\section*{EXTENDED DESCRIPTION}

\section*{CONSEQUENCES OF ERRORS}

The working directory shall remain unchanged.

\section*{APPLICATION USAGE}

Since \(c d\) affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:
```

(cd /tmp)
nohup cd
find . -exec cd {} \;

```
it does not affect the working directory of the caller's environment.
The user must have execute (search) permission in directory in order to change to it.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The use of the CDPATH was introduced in the System V shell. Its use is analogous to the use of the PATH variable in the shell. The BSD C shell used a shell parameter cdpath for this purpose.
A common extension when \(H O M E\) is undefined is to get the login directory from the user database for the invoking user. This does not occur on System \(V\) implementations.
Some historical shells, such as the KornShell, took special actions when the directory name contained a dot-dot component, selecting the logical parent of the directory, rather than the actual parent directory; that is, it moved up one level toward the '/' in the pathname, remembering what the user typed, rather than performing the equivalent of:
chdir(". ");
In such a shell, the following commands would not necessarily produce equivalent output for all directories:
```

cd .. \&\& ls ls..

```

This behavior is now the default. It is not consistent with the definition of dot-dot in most historical practice; that is, while this behavior has been optionally available in the KornShell, other shells have historically not supported this functionality. The logical pathname is stored in the \(P W D\) environment variable when the \(c d\) utility completes and this value is used to construct the next directory name if \(c d\) is invoked with the \(-\mathbf{L}\) option.

\section*{FUTURE DIRECTIONS}

\section*{None.}

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The \(c d\) - operand, \(P W D\), and \(O L D P W D\) are added.

The \(-\mathbf{L}\) and \(\mathbf{- P}\) options are added to align with the IEEE P1003.2b draft standard. This also includes the introduction of a new description to include the effect of these options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/14 is applied, changing the SYNOPSIS to make it clear that the \(-\mathbf{L}\) and \(-\mathbf{P}\) options are mutually-exclusive.
Issue 7
Austin Group Interpretation 1003.1-2001 \#037 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
cflow - generate a C-language flowgraph (DEVELOPMENT)

\section*{SYNOPSIS}

XSI Cflow [-r] [-d num] [-D name[=def]]... [-i incl] [-I dir]...
[-U dir]...file...

\section*{DESCRIPTION}

The cflow utility shall analyze a collection of object files or assembler, C-language, lex, or yacc source files, and attempt to build a graph, written to standard output, charting the external references.

\section*{OPTIONS}

The cflow utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the \(-\mathbf{D},-\mathbf{I}\), and \(-\mathbf{U}\) options (which are identical to their interpretation by c99) is significant.

The following options shall be supported:
-d num Indicate the depth at which the flowgraph is cut off. The application shall ensure that the argument num is a decimal integer. By default this is a very large number (typically greater than 32000 ). Attempts to set the cut-off depth to a non-positive integer shall be ignored.
-i incl Increase the number of included symbols. The incl option-argument is one of the following characters:
\(x \quad\) Include external and static data symbols. The default shall be to include only functions in the flowgraph.
- (Underscore) Include names that begin with an underscore. The default shall be to exclude these functions (and data if \(-\mathbf{i} \mathbf{x}\) is used).
-r Reverse the caller:callee relationship, producing an inverted listing showing the callers of each function. The listing shall also be sorted in lexicographical order by callee.

\section*{OPERANDS}

The following operand is supported:
file The pathname of a file for which a graph is to be generated. Filenames suffixed by .1 shall shall be taken to be lex input, .y as yacc input, .c as c99 input, and .i as the output of \(c 99-E\). Such files shall be processed as appropriate, determined by their suffix.
Files suffixed by .s (conventionally assembler source) may have more limited information extracted from them.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

The input files shall be object files or assembler, C-language, lex, or yacc source files.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of cflow:
\(L A N G \quad\) Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L \quad\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for the ordering of the output when the \(-\mathbf{r}\) option is used.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The flowgraph written to standard output shall be formatted as follows:
"\%d \%s:\%s\n", <reference number>, <global>, <definition>
Each line of output begins with a reference (that is, line) number, followed by indentation of at least one column position per level. This is followed by the name of the global, a colon, and its definition. Normally globals are only functions not defined as an external or beginning with an underscore; see the OPTIONS section for the -i inclusion option. For information extracted from C-language source, the definition consists of an abstract type declaration (for example, char *) and, delimited by angle brackets, the name of the source file and the line number where the definition was found. Definitions extracted from object files indicate the filename and location counter under which the symbol appeared (for example, text).

Once a definition of a name has been written, subsequent references to that name contain only the reference number of the line where the definition can be found. For undefined references, only "<>" shall be written.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

Files produced by lex and yacc cause the reordering of line number declarations, and this can confuse cflow. To obtain proper results, the input of yacc or lex must be directed to cflow.

\section*{EXAMPLES}

Given the following in file.c:
```

int i;
int f();
int g();
int h();
int
main()
{
f();
g();
f();
}
int
f()
{
i = h();
}
The command:

```
```

cflow -i x file.c

```
cflow -i x file.c
produces the output:
```

```
main: int(), <file.c 6>
```

main: int(), <file.c 6>
f: int(), <file.c 13>
f: int(), <file.c 13>
h:<>
h:<>
4 i: int, <file.c 1>

```
4 i: int, <file.c 1>
```

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
chgrp - change the file group ownership

## SYNOPSIS

```
chgrp [-h] group file...
chgrp -R [-H|-L|-P] group file...
```

## DESCRIPTION

The chgrp utility shall set the group ID of the file named by each file operand to the group ID specified by the group operand.
For each file operand, or, if the $-\mathbf{R}$ option is used, each file encountered while walking the directory trees specified by the file operands, the chgrp utility shall perform actions equivalent to the chown () function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

- The file operand shall be used as the path argument.
- The user ID of the file shall be used as the owner argument.
- The specified group ID shall be used as the group argument.

Unless chgrp is invoked by a process with appropriate privileges, the set-user-ID and set-groupID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

## OPTIONS

The chgrp utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-h If the system supports group IDs for symbolic links, for each file operand that names a file of type symbolic link, chgrp shall attempt to set the group ID of the symbolic link instead of the file referenced by the symbolic link. If the system does not support group IDs for symbolic links, for each file operand that names a file of type symbolic link, chgrp shall do nothing more with the current file and shall go on to any remaining files.
-H If the $-\mathbf{R}$ option is specified and a symbolic link referencing a file of type directory is specified on the command line, chgrp shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.
$-\mathbf{L} \quad$ If the $-\mathbf{R}$ option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, chgrp shall change the group of the directory referenced by the symbolic link and all files in the file hierarchy below it.

- $\mathbf{P} \quad$ If the $-\mathbf{R}$ option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, chgrp shall change the group ID of the symbolic link if the system supports this operation. The chgrp utility shall not follow the symbolic link to any other part of the file hierarchy.
$-\mathbf{R}$ Recursively change file group IDs. For each file operand that names a directory, chgrp shall change the group of the directory and all files in the file hierarchy below it. Unless a $-\mathbf{H},-\mathbf{L}$, or $-\mathbf{P}$ option is specified, it is unspecified which of these options will be used as the default.
Specifying more than one of the mutually-exclusive options $-\mathbf{H},-\mathbf{L}$, and $-\mathbf{P}$ shall not be
considered an error. The last option specified shall determine the behavior of the utility.

## OPERANDS

The following operands shall be supported:
group A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the file operands. If a numeric group operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.
file A pathname of a file whose group ID is to be modified.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of chgrp:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.
STDERR
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The utility executed successfully and all requested changes were made.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of chgrp to a user with appropriate privileges when the group specified is not the effective group ID or one of the supplementary group IDs of the calling process.

## EXAMPLES

## None.

## RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. The standard developers chose to mask these by specifying only 0 and $>0$ as exit values.
The functionality of chgrp is described substantially through references to chown(). In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.

## FUTURE DIRECTIONS

None.

New options $-\mathbf{H},-\mathbf{L}$, and $-\mathbf{P}$ are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

IEEE PASC Interpretation 1003.2 \#172 is applied, changing the CONSEQUENCES OF ERRORS section to "Default.".
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/15 is applied, changing the SYNOPSIS to make it clear that $-\mathbf{h}$ and $-\mathbf{R}$ are optional.

## Issue 7

SD5-XCU-ERN-8 is applied, removing the $-\mathbf{R}$ from the first line of the SYNOPSIS.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
chmod - change the file modes

## SYNOPSIS

```
chmod [-R] mode file...
```

## DESCRIPTION

The chmod utility shall change any or all of the file mode bits of the file named by each file operand in the way specified by the mode operand.

It is implementation-defined whether and how the chmod utility affects any alternate or additional file access control mechanism (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions) being used for the specified file.
Only a process whose effective user ID matches the user ID of the file, or a process with the appropriate privileges, shall be permitted to change the file mode bits of a file.

OPTIONS
The chmod utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-R Recursively change file mode bits. For each file operand that names a directory, chmod shall change the file mode bits of the directory and all files in the file hierarchy below it.

## OPERANDS

The following operands shall be supported:
mode $\quad$ Represents the change to be made to the file mode bits of each file named by one of the file operands; see the EXTENDED DESCRIPTION section.
file A pathname of a file whose file mode bits shall be modified.
STDIN
Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of chmod:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

## xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

The mode operand shall be either a symbolic_mode expression or a non-negative octal integer. The symbolic_mode form is described by the grammar later in this section.
Each clause shall specify an operation to be performed on the current file mode bits of each file. The operations shall be performed on each file in the order in which the clauses are specified.
The who symbols $\mathbf{u}, \mathbf{g}$, and $\mathbf{o}$ shall specify the user, group, and other parts of the file mode bits, respectively. A who consisting of the symbol a shall be equivalent to ugo.

The perm symbols $\mathbf{r}, \mathbf{w}$, and $\mathbf{x}$ represent the read, write, and execute/search portions of file mode bits, respectively. The perm symbol s shall represent the set-user-ID-on-execution (when who contains or implies $\mathbf{u}$ ) and set-group-ID-on-execution (when who contains or implies $\mathbf{g}$ ) bits.
The perm symbol $\mathbf{X}$ shall represent the execute/search portion of the file mode bits if the file is a directory or if the current (unmodified) file mode bits have at least one of the execute bits (S_IXUSR, S_IXGRP, or S_IXOTH) set. It shall be ignored if the file is not a directory and none of the execute bits are set in the current file mode bits.

The permcopy symbols $\mathbf{u}, \mathbf{g}$, and $\mathbf{o}$ shall represent the current permissions associated with the user, group, and other parts of the file mode bits, respectively. For the remainder of this section, perm refers to the non-terminals perm and permcopy in the grammar.
If multiple actionlists are grouped with a single wholist in the grammar, each actionlist shall be applied in the order specified with that wholist. The op symbols shall represent the operation performed, as follows:

+ If perm is not specified, the ${ }^{\prime}+{ }^{\prime}$ operation shall not change the file mode bits.
If who is not specified, the file mode bits represented by perm for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.
Otherwise, the file mode bits represented by the specified who and perm values shall be set.
- If perm is not specified, the ${ }^{\prime}-^{\prime}$ operation shall not change the file mode bits.

If who is not specified, the file mode bits represented by perm for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be cleared.
Otherwise, the file mode bits represented by the specified who and perm values shall be cleared.
$=$ Clear the file mode bits specified by the who value, or, if no who value is specified, all of the file mode bits specified in this volume of IEEE Std 1003.1-200x.
If perm is not specified, the ${ }^{\prime}={ }^{\prime}$ operation shall make no further modifications to the file mode bits.

If who is not specified, the file mode bits represented by perm for the owner, group, and other permissions, except for those with corresponding bits in the file mode creation mask of the invoking process, shall be set.
Otherwise, the file mode bits represented by the specified who and perm values shall be set.
When using the symbolic mode form on a regular file, it is implementation-defined whether or not:

- Requests to set the set-user-ID-on-execution or set-group-ID-on-execution bit when all execute bits are currently clear and none are being set are ignored.
- Requests to clear all execute bits also clear the set-user-ID-on-execution and set-group-ID-on-execution bits.
- Requests to clear the set-user-ID-on-execution or set-group-ID-on-execution bits when all execute bits are currently clear are ignored. However, if the command $l s-1$ file writes an $s$ in the position indicating that the set-user-ID-on-execution or set-group-ID-on-execution is set, the commands chmod $\mathbf{u}-\mathbf{s}$ file or chmod $\mathbf{g}-\mathbf{s}$ file, respectively, shall not be ignored.

When using the symbolic mode form on other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

If the who symbol $\mathbf{o}$ is used in conjunction with the perm symbol $\mathbf{s}$ with no other who symbols being specified, the set-user-ID-on-execution and set-group-ID-on-execution bits shall not be modified. It shall not be an error to specify the who symbol o in conjunction with the perm symbol s.
xSI The perm symbol $\mathbf{t}$ shall specify the S_ISVTX bit. When used with a file of type directory, it can be used with the who symbol a, or with no who symbol. It shall not be an error to specify a who symbol of $\mathbf{u}, \mathbf{g}$, or $\mathbf{o}$ in conjunction with the perm symbol $\mathbf{t}$, but the meaning of these combinations is unspecified. The effect when using the perm symbol $\mathbf{t}$ with any file type other than directory is unspecified.
For an octal integer mode operand, the file mode bits shall be set absolutely.
For each bit set in the octal number, the corresponding file permission bit shown in the following table shall be set; all other file permission bits shall be cleared. For regular files, for each bit set in the octal number corresponding to the set-user-ID-on-execution or the set-group-ID-onexecution, bits shown in the following table shall be set; if these bits are not set in the octal number, they are cleared. For other file types, it is implementation-defined whether or not requests to set or clear the set-user-ID-on-execution or set-group-ID-on-execution bits are honored.

XSI

| Octal | Mode Bit | Octal | Mode Bit | Octal | Mode Bit | Octal | Mode Bit |
| :---: | :--- | :---: | :--- | :---: | :--- | :---: | :---: |
| $\mathbf{4 0 0 0}$ | S_ISUID | $\mathbf{0 4 0 0}$ | S_IRUSR | $\mathbf{0 0 4 0}$ | S_IRGRP | $\mathbf{0 0 0 4}$ | S_IROTH |
| $\mathbf{2 0 0 0}$ | S_ISGID | $\mathbf{0 2 0 0}$ | S_IWUSR | $\mathbf{0 0 2 0}$ | S_IWGRP | $\mathbf{0 0 0 2}$ | S_IWOTH |
| $\mathbf{1 0 0 0}$ | S_ISVTX | $\mathbf{0 1 0 0}$ | S_IXUSR | $\mathbf{0 0 1 0}$ | S_IXGRP | $\mathbf{0 0 0 1}$ | S_IXOTH |

When bits are set in the octal number other than those listed in the table above, the behavior is unspecified.

## Grammar for chmod

The grammar and lexical conventions in this section describe the syntax for the symbolic_mode operand. The general conventions for this style of grammar are described in Section 1.10 (on page 18). A valid symbolic_mode can be represented as the non-terminal symbol symbolic_mode in the grammar. This formal syntax shall take precedence over the preceding text syntax description.

The lexical processing is based entirely on single characters. Implementations need not allow <blank>s within the single argument being processed.

## EXIT STATUS

The following exit values shall be returned:
0 The utility executed successfully and all requested changes were made.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Some implementations of the chmod utility change the mode of a directory before the files in the directory when performing a recursive ( $-\mathbf{R}$ option) change; others change the directory mode after the files in the directory. If an application tries to remove read or search permission for a file hierarchy, the removal attempt fails if the directory is changed first; on the other hand, trying to re-enable permissions to a restricted hierarchy fails if directories are changed last. Users should not try to make a hierarchy inaccessible to themselves.

Some implementations of chmod never used the umask of the process when changing modes; systems conformant with this volume of IEEE Std 1003.1-200x do so when who is not specified. Note the difference between:
chmod a-w file
which removes all write permissions, and:

```
chmod -- -w file
```

which removes write permissions that would be allowed if file was created with the same umask.

Conforming applications should never assume that they know how the set-user-ID and set-group-ID bits on directories are interpreted.

## EXAMPLES

| Mode | Results |
| :--- | :--- |
| $a+=$ | Equivalent to $a+, a=$; clears all file mode bits. <br> $g o+-w$ <br> Equivalent to $g o+, g o-w ;$ clears group and other <br> write bits. <br> $g=o-w$ |
| $g-r+w$ | Equivalent to $g=o, g-w$; sets group bit to match <br> other bits and then clears group write bit. <br> Equivalent to $g-r, g+w$; clears group read bit and <br> sets group write bit. <br> Sets owner bits to match group bits and sets <br> other bits to match group bits. |

## RATIONALE

The functionality of chmod is described substantially through references to concepts defined in the System Interfaces volume of IEEE Std 1003.1-200x. In this way, there is less duplication of effort required for describing the interactions of permissions. However, the behavior of this utility is not described in terms of the chmod () function from the System Interfaces volume of IEEE Std 1003.1-200x because that specification requires certain side effects upon alternate file access control mechanisms that might not be appropriate, depending on the implementation.

Implementations that support mandatory file and record locking as specified by the 1984 /usr/group standard historically used the combination of set-group-ID bit set and group execute bit clear to indicate mandatory locking. This condition is usually set or cleared with the symbolic mode perm symbol 1 instead of the perm symbols $\mathbf{s}$ and $\mathbf{x}$ so that the mandatory locking mode is not changed without explicit indication that that was what the user intended. Therefore, the details on how the implementation treats these conditions must be defined in the documentation. This volume of IEEE Std 1003.1-200x does not require mandatory locking (nor does the System Interfaces volume of IEEE Std 1003.1-200x), but does allow it as an extension. However, this volume of IEEE Std 1003.1-200x does require that the $l s$ and chmod utilities work consistently in this area. If $l s-1$ file indicates that the set-group-ID bit is set, chmod $\mathbf{g}-\mathbf{s}$ file must clear it (assuming appropriate privileges exist to change modes).
The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it
can overflow the range of valid exit status values. This problem is avoided here by specifying only 0 and $>0$ as exit values.
The System Interfaces volume of IEEE Std 1003.1-200x indicates that implementation-defined restrictions may cause the S_ISUID and S_ISGID bits to be ignored. This volume of IEEE Std 1003.1-200x allows the chmod utility to choose to modify these bits before calling chmod () (or some function providing equivalent capabilities) for non-regular files. Among other things, this allows implementations that use the set-user-ID and set-group-ID bits on directories to enable extended features to handle these extensions in an intelligent manner.
The $\mathbf{X}$ perm symbol was adopted from BSD-based systems because it provides commonly desired functionality when doing recursive ( $-\mathbf{R}$ option) modifications. Similar functionality is not provided by the find utility. Historical BSD versions of chmod, however, only supported X with $o p+$; it has been extended in this volume of IEEE Std 1003.1-200x because it is also useful with $o p=$. (It has also been added for $o p-$ even though it duplicates $\mathbf{x}$, in this case, because it is intuitive and easier to explain.)
The grammar was extended with the permcopy non-terminal to allow historical-practice forms of symbolic modes like $\mathbf{o}=\mathbf{u}-\mathbf{g}$ (that is, set the "other" permissions to the permissions of "owner" minus the permissions of "group").

## FUTURE DIRECTIONS

## None.

SEE ALSO
ls, umask, the System Interfaces volume of IEEE Std 1003.1-200x, chmod ()

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Octal modes have been kept and made mandatory despite being marked obsolescent in the ISO POSIX-2: 1993 standard.

IEEE PASC Interpretation 1003.2 \#172 is applied, changing the CONSEQUENCES OF ERRORS section to "Default.".

The Open Group Base Resolution bwg2001-010 is applied, adding the description of the S_ISVTX bit and the $\mathbf{t}$ perm symbol as part of the XSI option.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/16 is applied, changing the XSI shaded text in the EXTENDED DESCRIPTION from:
"The perm symbol $\mathbf{t}$ shall specify the S_ISVTX bit and shall apply to directories only. The effect when using it with any other file type is unspecified. It can be used with the who symbols $\mathbf{0}$, $\mathbf{a}$, or with no who symbol. It shall not be an error to specify a who symbol of $\mathbf{u}$ or $\mathbf{g}$ in conjunction with the perm symbol $\mathbf{t}$; it shall be ignored for $\mathbf{u}$ and $\mathbf{g}$."
to:
"The perm symbol $\mathbf{t}$ shall specify the S_ISVTX bit. When used with a file of type directory, it can be used with the who symbol a, or with no who symbol. It shall not be an error to specify a who symbol of $\mathbf{u}, \mathbf{g}$, or $\mathbf{o}$ in conjunction with the perm symbol $\mathbf{t}$, but the meaning of these combinations is unspecified. The effect when using the perm symbol $\mathbf{t}$ with any file type other than directory is unspecified."

This change is to permit historical behavior.

## NAME

chown - change the file ownership

## SYNOPSIS

```
chown [-h] owner[:group] file...
chown -R [-H|-L|-P ] owner[:group] file...
```

## DESCRIPTION

The chown utility shall set the user ID of the file named by each file operand to the user ID specified by the owner operand.
For each file operand, or, if the $-\mathbf{R}$ option is used, each file encountered while walking the directory trees specified by the file operands, the chown utility shall perform actions equivalent to the chown () function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

1. The file operand shall be used as the path argument.
2. The user ID indicated by the owner portion of the first operand shall be used as the owner argument.
3. If the group portion of the first operand is given, the group ID indicated by it shall be used as the group argument; otherwise, the group ownership shall not be changed.
Unless chown is invoked by a process with appropriate privileges, the set-user-ID and set-groupID bits of a regular file shall be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.

## OPTIONS

The chown utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-h If the system supports user IDs for symbolic links, for each file operand that names a file of type symbolic link, chown shall attempt to set the user ID of the symbolic link. If the system supports group IDs for symbolic links, and a group ID was specified, for each file operand that names a file of type symbolic link, chown shall attempt to set the group ID of the symbolic link. If the system does not support user or group IDs for symbolic links, for each file operand that names a file of type symbolic link, chown shall do nothing more with the current file and shall go on to any remaining files.
$-\mathbf{H} \quad$ If the $-\mathbf{R}$ option is specified and a symbolic link referencing a file of type directory is specified on the command line, chown shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.

- $\mathbf{L} \quad$ If the $-\mathbf{R}$ option is specified and a symbolic link referencing a file of type directory is specified on the command line or encountered during the traversal of a file hierarchy, chown shall change the user ID (and group ID, if specified) of the directory referenced by the symbolic link and all files in the file hierarchy below it.
$-\mathbf{P} \quad$ If the $-\mathbf{R}$ option is specified and a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, chown shall change the owner ID (and group ID, if specified) of the symbolic link if the system supports this operation. The chown utility shall not follow the symbolic link to any other part of the file hierarchy.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The utility executed successfully and all requested changes were made.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Only the owner of a file or the user with appropriate privileges may change the owner or group of a file.

Some implementations restrict the use of chown to a user with appropriate privileges.

## EXAMPLES

None.

## RATIONALE

The System V and BSD versions use different exit status codes. Some implementations used the exit status as a count of the number of errors that occurred; this practice is unworkable since it can overflow the range of valid exit status values. These are masked by specifying only 0 and $>0$ as exit values.
The functionality of chown is described substantially through references to functions in the System Interfaces volume of IEEE Std 1003.1-200x. In this way, there is no duplication of effort required for describing the interactions of permissions, multiple groups, and so on.
The 4.3 BSD method of specifying both owner and group was included in this volume of IEEE Std 1003.1-200x because.

- There are cases where the desired end condition could not be achieved using the chgrp and chown (that only changed the user ID) utilities. (If the current owner is not a member of the desired group and the desired owner is not a member of the current group, the chown() function could fail unless both owner and group are changed at the same time.)
- Even if they could be changed independently, in cases where both are being changed, there is a $100 \%$ performance penalty caused by being forced to invoke both utilities.
The BSD syntax user [.group] was changed to user[:group] in this volume of IEEE Std 1003.1-200x because the period is a valid character in login names (as specified by the Base Definitions volume of IEEE Std 1003.1-200x, login names consist of characters in the portable filename character set). The colon character was chosen as the replacement for the period character because it would never be allowed as a character in a user name or group name on historical implementations.
The $-\mathbf{R}$ option is considered by some observers as an undesirable departure from the historical UNIX system tools approach; since a tool, find, already exists to recurse over directories, there seemed to be no good reason to require other tools to have to duplicate that functionality. However, the $-\mathbf{R}$ option was deemed an important user convenience, is far more efficient than forking a separate process for each element of the directory hierarchy, and is in widespread historical use.

## FUTURE DIRECTIONS

None.

## SEE ALSO

chmod, chgrp, the System Interfaces volume of IEEE Std 1003.1-200x, chown ()

## CHANGE HISTORY

First released in Issue 2.
Issue 6
New options $-\mathbf{h},-\mathbf{H},-\mathbf{L}$, and $-\mathbf{P}$ are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.

The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE PASC Interpretation 1003.2 \#172 is applied, changing the CONSEQUENCES OF ERRORS section to "Default.".
The "otherwise, ..." text in item 3. of the DESCRIPTION is changed to "otherwise, the group ownership shall not be changed".
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/17 is applied, changing the SYNOPSIS to make it clear that $-\mathbf{h}$ and $-\mathbf{R}$ are optional.

Issue 7
SD5-XCU-ERN-9 is applied, removing the $-\mathbf{R}$ from the first line of the SYNOPSIS.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

cksum - write file checksums and sizes

## SYNOPSIS

```
cksum [file...]
```

## DESCRIPTION

The cksum utility shall calculate and write to standard output a cyclic redundancy check (CRC) for each input file, and also write to standard output the number of octets in each file. The CRC used is based on the polynomial used for CRC error checking in the ISO/IEC 8802-3:1996 standard (Ethernet).
The encoding for the CRC checksum is defined by the generating polynomial:

$$
G(x)=x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+x^{5}+x^{4}+x^{2}+x+1
$$

Mathematically, the CRC value corresponding to a given file shall be defined by the following procedure:

1. The $n$ bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These $n$ bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer shall be used.
2. $M(x)$ is multiplied by $x^{32}$ (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree $\leq 31$.
3. The coefficients of $R(x)$ are considered to be a 32 -bit sequence.
4. The bit sequence is complemented and the result is the CRC.

## OPTIONS

None.

## OPERANDS

The following operand shall be supported:
file A pathname of a file to be checked. If no file operands are specified, the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

The input files can be any file type.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of cksum:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

For each file processed successfully, the cksum utility shall write in the following format:
"\%u \%d \%s\n", <checksum>, <\# of octets>, <pathname>
If no file operand was specified, the pathname and its leading <space> shall be omitted.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All files were processed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The cksum utility is typically used to quickly compare a suspect file against a trusted version of the same, such as to ensure that files transmitted over noisy media arrive intact. However, this comparison cannot be considered cryptographically secure. The chances of a damaged file producing the same CRC as the original are small; deliberate deception is difficult, but probably not impossible.
Although input files to cksum can be any type, the results need not be what would be expected on character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-200x. Since this volume of IEEE Std 1003.1-200x does not specify the block size used when doing input, checksums of character special files need not process all of the data in those files.

The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as changing little-endian byte ordering to big-endian), identical CRC values cannot be expected. Implementations performing such transformations may extend cksum to handle such situations.

## EXAMPLES

## RATIONALE

The following C-language program can be used as a model to describe the algorithm. It assumes that a char is one octet. It also assumes that the entire file is available for one pass through the function. This was done for simplicity in demonstrating the algorithm, rather than as an implementation model.

unsigned long memcrc(const unsigned char *b, size_t n)
{
/* Input arguments:
    * const char* b == byte sequence to checksum
    * size_t n == length of sequence
    */
        register unsigned i, c, s = 0;
        for (i = n; i > 0; --i) {
        c = (unsigned) (*b + ) ;
        s = (s << 8) ^ crctab[(s >> 24) ^ c];
        }
        /* Extend with the length of the string. */
        while (n != 0) {
        c = n & 0377;
        n >>= 8;
        s=(s<< 8)^ crctab[(s >> 24)^c];
        }
        return ~ s
}
```

The historical practice of writing the number of "blocks" has been changed to writing the number of octets, since the latter is not only more useful, but also since historical implementations have not been consistent in defining what a "block" meant.

The algorithm used was selected to increase the operational robustness of cksum. Neither the System V nor BSD sum algorithm was selected. Since each of these was different and each was the default behavior on those systems, no realistic compromise was available if either were selected-some set of historical applications would break. Therefore, the name was changed to cksum. Although the historical sum commands will probably continue to be provided for many years, programs designed for portability across systems should use the new name.
The algorithm selected is based on that used by the ISO/IEC 8802-3: 1996 standard (Ethernet) for the frame check sequence field. The algorithm used does not match the technical definition of a checksum; the term is used for historical reasons. The length of the file is included in the CRC calculation because this parallels inclusion of a length field by Ethernet in its CRC, but also because it guards against inadvertent collisions between files that begin with different series of zero octets. The chance that two different files produce identical CRCs is much greater when their lengths are not considered. Keeping the length and the checksum of the file itself separate would yield a slightly more robust algorithm, but historical usage has always been that a single number (the checksum as printed) represents the signature of the file. It was decided that historical usage was the more important consideration.

Early proposals contained modifications to the Ethernet algorithm that involved extracting table values whenever an intermediate result became zero. This was demonstrated to be less robust than the current method and mathematically difficult to describe or justify.

The calculation used is identical to that given in pseudo-code in the referenced Sarwate article. The pseudo-code rendition is:

```
X <- 0; Y <- 0;
for i <- m -1 step -1 until 0 do
    begin
    T <- X(1) ^ A[i];
    X(1) <- X(0); X(0) <- Y(1); Y(1) <- Y(0); Y(0) <- 0;
    comment: f[T] and f'[T] denote the T-th words in the
                table f and f' ;
    X <- X ^ f[T]; Y <- Y ^ f'[T];
    end
```

The pseudo-code is reproduced exactly as given; however, note that in the case of cksum, $\mathbf{A}[\mathrm{i}]$ represents a byte of the file, the words $\mathbf{X}$ and $\mathbf{Y}$ are treated as a single 32-bit value, and the tables $\mathbf{f}$ and $\mathbf{f}^{\prime}$ are a single table containing 32-bit values.
The referenced Sarwate article also discusses generating the table.

NAME
cmp - compare two files

## SYNOPSIS

cmp [-l|-s] file1 file2

DESCRIPTION
The cmp utility shall compare two files. The cmp utility shall write no output if the files are the same. Under default options, if they differ, it shall write to standard output the byte and line number at which the first difference occurred. Bytes and lines shall be numbered beginning with 1.

OPTIONS
The cmp utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-1 (Lowercase ell.) Write the byte number (decimal) and the differing bytes (octal) for each difference.
-s Write nothing for differing files; return exit status only.

## OPERANDS

The following operands shall be supported:
file1 A pathname of the first file to be compared. If file1 is ${ }^{\prime}-^{\prime}$, the standard input shall be used.
file2 A pathname of the second file to be compared. If file2 is $r-r$, the standard input shall be used.

If both file1 and file2 refer to standard input or refer to the same FIFO special, block special, or character special file, the results are undefined.

## STDIN

The standard input shall be used only if the file1 or file 2 operand refers to standard input. See the INPUT FILES section.

## INPUT FILES

The input files can be any file type.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of cmp:
$L A N G \quad$ Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

STDOUT
In the POSIX locale, results of the comparison shall be written to standard output. When no options are used, the format shall be:

```
"%s %s differ: char %d, line %d\n", file1, file2,
    <byte number>, <line number>
```

When the $-\mathbf{l}$ option is used, the format shall be:

```
"%d %o %o\n", <byte number>, <differing byte>,
    <differing byte>
```

for each byte that differs. The first <differing byte> number is from file1 while the second is from file2. In both cases, <byte number> shall be relative to the beginning of the file, beginning with 1.
No output shall be written to standard output when the -s option is used.

## STDERR

The standard error shall be used only for diagnostic messages. If the -1 option is used and file1 and file2 differ in length, or if the -s option is not used and file1 and file2 are identical for the entire length of the shorter file, in the POSIX locale the following diagnostic message shall be written:

```
"cmp: EOF on %s%s\n", <name of shorter file>, <additional info>
```

The <additional info> field shall either be null or a string that starts with a <blank> and contains no <newline>s. Some implementations report on the number of lines in this case.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The files are identical.
1 The files are different; this includes the case where one file is identical to the first part of the other.
>1 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Although input files to $c m p$ can be any type, the results might not be what would be expected on character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-200x. Since this volume of IEEE Std 1003.1-200x does not specify the block size used when doing input, comparisons of character special files need not compare all of the data in those files.
For files which are not text files, line numbers simply reflect the presence of a <newline>, without any implication that the file is organized into lines.

## EXAMPLES

None.

## RATIONALE

The global language in Section 1.11 indicates that using two mutually-exclusive options together produces unspecified results. Some System V implementations consider the option usage:

```
cmp -l -s ...
```

to be an error. They also treat:

```
cmp -s -l ...
```

as if no options were specified. Both of these behaviors are considered bugs, but are allowed.
The word char in the standard output format comes from historical usage, even though it is actually a byte number. When cmp is supported in other locales, implementations are encouraged to use the word byte or its equivalent in another language. Users should not interpret this difference to indicate that the functionality of the utility changed between locales.
Some implementations report on the number of lines in the identical-but-shorter file case. This is allowed by the inclusion of the <additional info> fields in the output format. The restriction on having a leading <blank> and no <newline>s is to make parsing for the filename easier. It is recognized that some filenames containing white-space characters make parsing difficult anyway, but the restriction does aid programs used on systems where the names are predominantly well behaved.

## FUTURE DIRECTIONS

None.

Issue 7
SD5-XCU-ERN-96 is applied, updating the STDERR section.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
comm - select or reject lines common to two files

## SYNOPSIS

```
comm [-123] file1 file2
```

## DESCRIPTION

The comm utility shall read file1 and file2, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in file1, lines only in file2, and lines in both files.

If the lines in both files are not ordered according to the collating sequence of the current locale, the results are unspecified.

## OPTIONS

The comm utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-1 Suppress the output column of lines unique to file1.
-2 Suppress the output column of lines unique to file2.
-3 Suppress the output column of lines duplicated in file1 and file2.
OPERANDS
The following operands shall be supported:
file1 A pathname of the first file to be compared. If file 1 is ${ }^{\prime}-\prime$, the standard input shall be used.
file2 A pathname of the second file to be compared. If file2 is ${ }^{\prime} \mathbf{~}^{\prime}$, the standard input shall be used.

If both file1 and file 2 refer to standard input or to the same FIFO special, block special, or character special file, the results are undefined.

## STDIN

The standard input shall be used only if one of the file1 or file 2 operands refers to standard input. See the INPUT FILES section.

## INPUT FILES

The input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of comm:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the collating sequence comm expects to have been used when the input files were sorted.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The comm utility shall produce output depending on the options selected. If the $\mathbf{- 1}, \mathbf{- 2}$, and $\mathbf{- 3}$ options are all selected, comm shall write nothing to standard output.
If the $\mathbf{- 1}$ option is not selected, lines contained only in file1 shall be written using the format:
"\%s\n", <line in filel>
If the $\mathbf{- 2}$ option is not selected, lines contained only in file 2 are written using the format:
"\%s\%s\n", <lead>, <line in file2>
where the string <lead> is as follows:
$<$ tab $\quad$ The $\mathbf{- 1}$ option is not selected.
null string The $\mathbf{- 1}$ option is selected.
If the $\mathbf{- 3}$ option is not selected, lines contained in both files shall be written using the format:
"\%s\%s\n", <lead>, <line in both>
where the string <lead> is as follows:
<tab><tab> Neither the $\mathbf{- 1}$ nor the $\mathbf{- 2}$ option is selected.
$<$ tab $\quad$ Exactly one of the $\mathbf{- 1}$ and $\mathbf{- 2}$ options is selected.
null string Both the $\mathbf{- 1}$ and $\mathbf{- 2}$ options are selected.
If the input files were ordered according to the collating sequence of the current locale, the lines written shall be in the collating sequence of the original lines.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were successfully output as specified.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

If the input files are not properly presorted, the output of comm might not be useful.

## EXAMPLES

If a file named xcu contains a sorted list of the utilities in this volume of IEEE Std 1003.1-200x, a file named xpg3 contains a sorted list of the utilities specified in the X/Open Portability Guide, Issue 3, and a file named svid89 contains a sorted list of the utilities in the System V Interface Definition Third Edition:

```
comm -23 xcu xpg3 | comm -23 - svid89
```

would print a list of utilities in this volume of IEEE Std 1003.1-200x not specified by either of the other documents:

```
comm -12 xcu xpg3 | comm -12 - svid89
```

would print a list of utilities specified by all three documents, and:

```
comm -12 xpg3 svid89 | comm -23 - xcu
```

would print a list of utilities specified by both XPG3 and the SVID, but not specified in this volume of IEEE Std 1003.1-200x.

NAME
command - execute a simple command

## SYNOPSIS

```
command [-p] command_name [argument...]
command [-v | - V] command_name
```

## DESCRIPTION

The command utility shall cause the shell to treat the arguments as a simple command, suppressing the shell function lookup that is described in Section 2.9.1.1 (on page 48), item 1 b.
If the command_name is the same as the name of one of the special built-in utilities, the special properties in the enumerated list at the beginning of Section 2.14 shall not occur. In every other respect, if command_name is not the name of a function, the effect of command (with no options) shall be the same as omitting command.
When the $-\mathbf{v}$ or $\mathbf{- V}$ option is used, the command utility shall provide information concerning how a command name is interpreted by the shell.

## OPTIONS

The command utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
$-\mathbf{p} \quad$ Perform the command search using a default value for PATH that is guaranteed to find all of the standard utilities.
-v Write a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment (see Section 2.12 (on page 61)), to invoke_command_name, but do not invoke command_name.

- Utilities, regular built-in utilities, command_names including a slash character, and any implementation-defined functions that are found using the PATH variable (as described in Section 2.9.1.1 (on page 48)), shall be written as absolute pathnames.
- Shell functions, special built-in utilities, regular built-in utilities not associated with a PATH search, and shell reserved words shall be written as just their names.
- An alias shall be written as a command line that represents its alias definition.
- Otherwise, no output shall be written and the exit status shall reflect that the name was not found.
-V Write a string to standard output that indicates how the name given in the command_name operand will be interpreted by the shell, in the current shell execution environment (see Section 2.12 (on page 61)), but do not invoke command_name. Although the format of this string is unspecified, it shall indicate in which of the following categories command_name falls and shall include the information stated:
- Utilities, regular built-in utilities, and any implementation-defined functions that are found using the PATH variable (as described in Section 2.9.1.1 (on page 48)), shall be identified as such and include the absolute pathname in the string.
- Other shell functions shall be identified as functions.
- Aliases shall be identified as aliases and their definitions included in the string.
- Special built-in utilities shall be identified as special built-in utilities.
- Regular built-in utilities not associated with a PATH search shall be identified as regular built-in utilities. (The term "regular" need not be used.)
- Shell reserved words shall be identified as reserved words.

## OPERANDS

The following operands shall be supported:
argument One of the strings treated as an argument to command_name.
command_name
The name of a utility or a special built-in utility.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of command:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the search path used during the command search described in Section 2.9.1.1 (on page 48), except as described under the - $\mathbf{p}$ option.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

When the $-\mathbf{v}$ option is specified, standard output shall be formatted as:
"\%s\n", <pathname or command>
When the $-\mathbf{V}$ option is specified, standard output shall be formatted as:
"\%s\n", <unspecified>

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## None.

## EXIT STATUS

When the $-\mathbf{v}$ or $-\mathbf{V}$ options are specified, the following exit values shall be returned:
0 Successful completion.
$>0$ The command_name could not be found or an error occurred.
Otherwise, the following exit values shall be returned:
126 The utility specified by command_name was found but could not be invoked.
127 An error occurred in the command utility or the utility specified by command_name could not be found.

Otherwise, the exit status of command shall be that of the simple command specified by the arguments to command.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The order for command search allows functions to override regular built-ins and path searches. This utility is necessary to allow functions that have the same name as a utility to call the utility (instead of a recursive call to the function).
The system default path is available using getconf; however, since getconf may need to have the PATH set up before it can be called itself, the following can be used:
command -p getconf _CS_PATH
There are some advantages to suppressing the special characteristics of special built-ins on occasion. For example:
command exec >unwritable-file
does not cause a non-interactive script to abort, so that the output status can be checked by the script.
The command, env, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

Since the $\mathbf{- v}$ and $\mathbf{- V}$ options of command produce output in relation to the current shell execution environment, command is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(PATH=foo command -v)
    nohup command -v
```

it does not necessarily produce correct results. For example, when called with nohup or an exec function, in a separate utility execution environment, most implementations are not able to identify aliases, functions, or special built-ins.
Two types of regular built-ins could be encountered on a system and these are described separately by command. The description of command search in Section 2.9.1.1 allows for a standard utility to be implemented as a regular built-in as long as it is found in the appropriate place in a PATH search. So, for example, command -v true might yield /bin/true or some similar pathname. Other implementation-defined utilities that are not defined by this volume of IEEE Std 1003.1-200x might exist only as built-ins and have no pathname associated with them. These produce output identified as (regular) built-ins. Applications encountering these are not able to count on execing them, using them with nohup, overriding them with a different PATH, and so on.

## EXAMPLES

1. Make a version of $c d$ that always prints out the new working directory exactly once:
```
cd() {
        command cd "$@" >/dev/null
        pwd
}
```

2. Start off a "secure shell script" in which the script avoids being spoofed by its parent:

At this point, given correct permissions on the directories called by PATH, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this volume of IEEE Std 1003.1-200x, but it is not prohibited as an extension. For example, the ENV variable precedes the invocation of the script with a user start-up script. Such a script could define functions to spoof the application.

## RATIONALE

Since command is a regular built-in utility it is always found prior to the PATH search.
There is nothing in the description of command that implies the command line is parsed any differently from that of any other simple command. For example:
command a $\mid$ b ; c
is not parsed in any special way that causes $\left.{ }^{\prime}\right|^{\prime}$ or ${ }^{\prime}$; ' $^{\prime}$ to be treated other than a pipe operator or semicolon or that prevents function lookup on $\mathbf{b}$ or $\mathbf{c}$.
The command utility is somewhat similar to the Eighth Edition shell builtin command, but since
command also goes to the file system to search for utilities, the name builtin would not be intuitive.

The command utility is most likely to be provided as a regular built-in. It is not listed as a special built-in for the following reasons:

- The removal of exportable functions made the special precedence of a special built-in unnecessary.
- A special built-in has special properties (see Section 2.14 (on page 64)) that were inappropriate for invoking other utilities. For example, two commands such as:
date > unwritable-file
command date > unwritable-file
would have entirely different results; in a non-interactive script, the former would continue to execute the next command, the latter would abort. Introducing this semantic difference along with suppressing functions was seen to be non-intuitive.

The -p option is present because it is useful to be able to ensure a safe path search that finds all the standard utilities. This search might not be identical to the one that occurs through one of the exec functions (as defined in the System Interfaces volume of IEEE Std 1003.1-200x) when PATH is unset. At the very least, this feature is required to allow the script to access the correct version of getconf so that the value of the default path can be accurately retrieved.
The command $\mathbf{- v}$ and $-\mathbf{V}$ options were added to satisfy requirements from users that are currently accomplished by three different historical utilities: type in the System V shell, whence in the KornShell, and which in the $C$ shell. Since there is no historical agreement on how and what to accomplish here, the POSIX command utility was enhanced and the historical utilities were left unmodified. The $C$ shell which merely conducts a path search. The KornShell whence is more elaborate-in addition to the categories required by POSIX, it also reports on tracked aliases, exported aliases, and undefined functions.
The output format of $-\mathbf{V}$ was left mostly unspecified because human users are its only audience. Applications should not be written to care about this information; they can use the output of $-\mathbf{v}$ to differentiate between various types of commands, but the additional information that may be emitted by the more verbose $-\mathbf{V}$ is not needed and should not be arbitrarily constrained in its verbosity or localization for application parsing reasons.

## SYNOPSIS <br> sinorsis

## compress - compress data

XSI

## DESCRIPTION

 Ziv coding algorithm. compressed to the standard output.
## OPTIONS

 Section 12.2, Utility Syntax Guidelines.The following options shall be supported:
$9<=$ bits <= 14 or 16. no . Z files are created.

## OPERANDS

The following operand shall be supported:

## STDIN

```
compress [-fv] [-b bits] [file...]
    compress [-cfv] [-b bits] [file]
```

The compress utility shall attempt to reduce the size of the named files by using adaptive Lempel-

Note: Lempel-Ziv is US Patent 4464650, issued to William Eastman, Abraham Lempel, Jacob Ziv, Martin Cohn on August 7th, 1984, and assigned to Sperry Corporation.
Lempel-Ziv-Welch compression is covered by US Patent 4558302, issued to Terry A. Welch on December 10th, 1985, and assigned to Sperry Corporation.
On systems not supporting adaptive Lempel-Ziv coding algorithm, the input files shall not be changed and an error value greater than two shall be returned. Except when the output is to the standard output, each file shall be replaced by one with the extension .Z. If the invoking process has appropriate privileges, the ownership, modes, access time, and modification time of the original file are preserved. If appending the. Z to the filename would make the name exceed \{NAME_MAX\} bytes, the command shall fail. If no files are specified, the standard input shall be

The compress utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x,
-b bits Specify the maximum number of bits to use in a code. For a conforming application, the bits argument shall be:

The implementation may allow bits values of greater than 14 . The default is 14,15 ,
-c Cause compress to write to the standard output; the input file is not changed, and
$-\mathbf{f} \quad$ Force compression of file, even if it does not actually reduce the size of the file, or if the corresponding file. Z file already exists. If the $-\mathbf{f}$ option is not given, and the process is not running in the background, the user is prompted as to whether an existing file.Z file should be overwritten.
$\mathbf{- v} \quad$ Write the percentage reduction of each file to standard error.
file A pathname of a file to be compressed.

The standard input shall be used only if no file operands are specified, or if a file operand is ' - .

## INPUT FILES

If file operands are specified, the input files contain the data to be compressed.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of compress:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as

## APPLICATION USAGE

The amount of compression obtained depends on the size of the input, the number of bits per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by $50-60 \%$. Compression is generally much better than that achieved by Huffman coding or adaptive Huffman coding (compact), and takes less time to compute.

Although compress strictly follows the default actions upon receipt of a signal or when an error occurs, some unexpected results may occur. In some implementations it is likely that a partially compressed file is left in place, alongside its uncompressed input file. Since the general operation of compress is to delete the uncompressed file only after the. $\mathbf{Z}$ file has been successfully filled, an application should always carefully check the exit status of compress before arbitrarily deleting files that have like-named neighbors with $\mathbf{Z}$ suffixes.
The limit of 14 on the bits option-argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

cp — copy files

## SYNOPSIS

cp [-fip] source_file target_file
cp [-fip] source_file... target
cp -R [-H|-L|-P] [-fip] source_file... target

## DESCRIPTION

The first synopsis form is denoted by two operands, neither of which are existing files of type directory. The $c p$ utility shall copy the contents of source_file (or, if source_file is a file of type symbolic link, the contents of the file referenced by source_file) to the destination path named by target file.
The second synopsis form is denoted by two or more operands where the $-\mathbf{R}$ option is not specified and the first synopsis form is not applicable. It shall be an error if any source_file is a file of type directory, if target does not exist, or if target does not name a directory. The $c p$ utility shall copy the contents of each source_file (or, if source_file is a file of type symbolic link, the contents of the file referenced by source_file) to the destination path named by the concatenation of target, a slash character, and the last component of source file.
The third and fourth synopsis forms are denoted by two or more operands where the $-\mathbf{R}$ option is specified. The $c p$ utility shall copy each file in the file hierarchy rooted in each source file to a destination path named as follows:

- If target exists and names an existing directory, the name of the corresponding destination path for each file in the file hierarchy shall be the concatenation of target, a slash character, and the pathname of the file relative to the directory containing source file.
- If target does not exist and two operands are specified, the name of the corresponding destination path for source_file shall be target; the name of the corresponding destination path for all other files in the file hierarchy shall be the concatenation of target, a slash character, and the pathname of the file relative to source_file.
It shall be an erron if target does not exist and more than two operands are specified, or if target exists and does not name a directory
In the following description, the term dest file refers to the file named by the destination path. The term source_file refers to the file that is being copied, whether specified as an operand or a file in a file hierarchy rooted in a source_file operand. If source_file is a file of type symbolic link:
- If the $-\mathbf{R}$ option was not specified, $c p$ shall take actions based on the type and contents of the file referenced by the symbolic link, and not by the symbolic link itself.
- If the - $\mathbf{R}$ option was specified:
- If none of the options $-\mathbf{H},-\mathbf{L}$, nor $-\mathbf{P}$ were specified, it is unspecified which of $-\mathbf{H}$, $-\mathbf{L}$, or $-\mathbf{P}$ will be used as a default.
- If the - $\mathbf{H}$ option was specified, $c p$ shall take actions based on the type and contents of the file referenced by any symbolic link specified as a source_file operand.
- If the -L option was specified, $c p$ shall take actions based on the type and contents of the file referenced by any symbolic link specified as a source file operand or any symbolic links encountered during traversal of a file hierarchy.
- If the - $\mathbf{P}$ option was specified, $c p$ shall copy any symbolic link specified as a source_file operand and any symbolic links encountered during traversal of a file hierarchy, and shall not follow any symbolic links.
For each source_file, the following steps shall be taken:

1. If source file references the same file as dest_file, $c p$ may write a diagnostic message to standard error; it shall do nothing more with source_file and shall go on to any remaining files.
2. If source_file is of type directory, the following steps shall be taken:
a. If the $-\mathbf{R}$ option was not specified, $c p$ shall write a diagnostic message to standard error, do nothing more with source_file, and go on to any remaining files.
b. If source_file was not specified as an operand and source_file is dot or dot-dot, $c p$ shall do nothing more with source_file and go on to any remaining files.
c. If dest_file exists and it is a file type not specified by the System Interfaces volume of IEEE Std 1003.1-200x, the behavior is implementation-defined.
d. If dest_file exists and it is not of type directory, $c p$ shall write a diagnostic message to standard error, do nothing more with source_file or any files below source_file in the file hierarchy, and go on to any remaining files.
e. If the directory dest file does not exist, it shall be created with file permission bits set to the same value as those of source_file, modified by the file creation mask of the user if the - $\mathbf{p}$ option was not specified, and then bitwise-inclusively OR'ed with S_IRWXU. If dest_file cannot be created, $c p$ shall write a diagnostic message to standard error, do nothing more with source_file, and go on to any remaining files. It is unspecified if $c p$ attempts to copy files in the file hierarchy rooted in source_file.
f. The files in the directory source_file shall be copied to the directory dest_file, taking the four steps ( 1 to 4 ) listed here with the files as source_files.
g. If dest_file was created, its file permission bits shall be changed (if necessary) to be the same as those of source_file, modified by the file creation mask of the user if the -p option was not specified.
h. The $c p$ utility shall do nothing more with source_file and go on to any remaining files.
3. If source file is of type regular file, the following steps shall be taken:
a. If dest-file exists, the following steps shall be taken:
i. If the -i option is in effect, the $c p$ utility shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, $c p$ shall do nothing more with source_file and go on to any remaining files.
ii. A file descriptor for dest_file shall be obtained by performing actions equivalent to the open () function defined in the System Interfaces volume of IEEE Std 1003.1-200x called using destfile as the path argument, and the bitwise-inclusive OR of O_WRONLY and O_TRUNC as the oflag argument.
iii. If the attempt to obtain a file descriptor fails and the -f option is in effect, $c p$ shall attempt to remove the file by performing actions equivalent to the unlink() function defined in the System Interfaces volume of IEEE Std 1003.1-200x called using dest_file as the path argument. If this attempt succeeds, $c p$ shall continue with step 3 b .
b. If dest_file does not exist, a file descriptor shall be obtained by performing actions equivalent to the open() function defined in the System Interfaces volume of IEEE Std 1003.1-200x called using dest_file as the path argument, and the bitwiseinclusive OR of O_WRONLY and O_CREAT as the oflag argument. The file permission bits of source_file shall be the mode argument.
c. If the attempt to obtain a file descriptor fails, $c p$ shall write a diagnostic message to standard error, do nothing more with source_file, and go on to any remaining files.
d. The contents of source file shall be written to the file descriptor. Any write errors shall cause $c p$ to write a diagnostic message to standard error and continue to step 3 e .
e. The file descriptor shall be closed.
f. The $c p$ utility shall do nothing more with source_file. If a write error occurred in step 3d, it is unspecified if $c p$ continues with any remaining files. If no write error occurred in step 3d, $c p$ shall go on to any remaining files.
4. Otherwise, the following steps shall be taken:
a. If the $-\mathbf{R}$ option was specified, the following steps shall be taken:
i. The dest_file shall be created with the same file type as source_file.
ii. If source_file is a file of type FIFO, the file permission bits shall be the same as those of source-file, modified by the file creation mask of the user if the -p option was not specified. Otherwise, the permissions, owner ID, and group ID of dest file are implementation-defined.
If this creation fails for any reason, $c p$ shall write a diagnostic message to standard error, do nothing more with source-file, and go on to any remaining files.
iii. If source_file is a file of type symbolic link, and the options require the symbolic link itself to be acted upon, the pathname contained in dest_file shall be the same as the pathname contained in source_file.

If this fails for any reason, $c p$ shall write a diagnostic message to standard error, do nothing more with source file, and go on to any remaining files.
If the implementation provides additional or alternate access control mechanisms (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions), their effect on copies of files is implementation-defined.

## OPTIONS

The $c p$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-f If a file descriptor for a destination file cannot be obtained, as described in step 3.a.ii., attempt to unlink the destination file and proceed.
-H Take actions based on the type and contents of the file referenced by any symbolic link specified as a source_file operand.
-i Write a prompt to standard error before copying to any existing non-directory destination file. If the response from the standard input is affirmative, the copy shall be attempted; otherwise, it shall not.
-L Take actions based on the type and contents of the file referenced by any symbolic link specified as a source file operand or any symbolic links encountered during traversal of a file hierarchy.
-P Take actions on any symbolic link specified as a sourcefile operand or any symbolic link encountered during traversal of a file hierarchy.
-p Duplicate the following characteristics of each source file in the corresponding destination file:

1. The time of last data modification and time of last access. If this duplication fails for any reason, $c p$ shall write a diagnostic message to standard error.
2. The user ID and group ID. If this duplication fails for any reason, it is unspecified whether $c p$ writes a diagnostic message to standard error.
3. The file permission bits and the S_ISUID and S_ISGID bits. Other, implementation-defined, bits may be duplicated as well. If this duplication fails for any reason, $c p$ shall write a diagnostic message to standard error.

If the user ID or the group ID cannot be duplicated, the file permission bits S_ISUID and S_ISGID shall be cleared. If these bits are present in the source file but are not duplicated in the destination file, it is unspecified whether $c p$ writes a diagnostic message to standard error.

The order in which the preceding characteristics are duplicated is unspecified. The dest_file shall not be deleted if these characteristics cannot be preserved.
$-\mathbf{R} \quad$ Copy file hierarchies.
Specifying more than one of the mutually-exclusive options $-\mathbf{H},-\mathbf{L}$, and $-\mathbf{P}$ shall not be considered an error. The last option specified shall determine the behavior of the utility.

## OPERANDS

The following operands shall be supported:
sourcefile A pathname of a file to be copied.
target file A pathname of an existing or nonexistent file, used for the output when a single file is copied.
target A pathname of a directory to contain the copied files.
STDIN
The standard input shall be used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used.

## INPUT FILES

The input files specified as operands may be of any file type.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $c p$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L \quad$ If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements used in the extended regular expression defined for
the yesexpr locale keyword in the LC_MESSAGES category.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

A prompt shall be written to standard error under the conditions specified in the DESCRIPTION section. The prompt shall contain the destination pathname, but its format is otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The output files may be of any type.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All files were copied successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If $c p$ is prematurely terminated by a signal or error, files or file hierarchies may be only partially copied and files and directories may have incorrect permissions or access and modification times.

## APPLICATION USAGE

The set-user-ID and set-group-ID bits are explicitly cleared when files are created. This is to prevent users from creating programs that are set-user-ID or set-group-ID to them when copying files or to make set-user-ID or set-group-ID files accessible to new groups of users. For example, if a file is set-user-ID and the copy has a different group ID than the source, a new group of users has execute permission to a set-user-ID program than did previously. In particular, this is a problem for superusers copying users' trees.

## EXAMPLES

None.

## RATIONALE

The -i option exists on BSD systems, giving applications and users a way to avoid accidentally removing files when copying. Although the 4.3 BSD version does not prompt if the standard input is not a terminal, the standard developers decided that use of $-\mathbf{i}$ is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds on standard input.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application using the $\mathbf{- i}$ option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.

The $-\mathbf{p}$ option is historical practice on BSD systems, duplicating the time of last data modification and time of last access. This volume of IEEE Std 1003.1-200x extends it to preserve the user and group IDs, as well as the file permissions. This requirement has obvious problems in that the directories are almost certainly modified after being copied. This volume of IEEE Std 1003.1-200x requires that the modification times be preserved. The statement that the order in which the characteristics are duplicated is unspecified is to permit implementations to provide the maximum amount of security for the user. Implementations should take into account the obvious security issues involved in setting the owner, group, and mode in the wrong order or creating files with an owner, group, or mode different from the final value.
It is unspecified whether $c p$ writes diagnostic messages when the user and group IDs cannot be set due to the widespread practice of users using $-\mathbf{p}$ to duplicate some portion of the file characteristics, indifferent to the duplication of others. Historic implementations only write diagnostic messages on errors other than [EPERM].

Earlier versions of this standard included support for the $-\mathbf{r}$ option to copy file hierarchies. The $-\mathbf{r}$ option is historical practice on BSD and BSD-derived systems. This option is no longer specified by this standard but may be present in some implementations. The - $\mathbf{R}$ option was added as a close synonym to the -r option, selected for consistency with all other options in this volume of IEEE Std 1003.1-200x that do recursive directory descent.
The difference between $\mathbf{- R}$ and the removed -r option is in the treatment by $c p$ of file types other than regular and directory. It was implementation-defined how the - option treated special files to allow both historical implementations and those that chose to support -r with the same abilities as - $\mathbf{R}$ defined by this volume of IEEE Std 1003.1-200x. The original -r flag, for historic reasons, did not handle special files any differently from regular files, but always read the file and copied its contents. This had obvious problems in the presence of special file types; for example, character devices, FIFOs, and sockets.

When a failure occurs during the copying of a file hierarchy, $c p$ is required to attempt to copy files that are on the same level in the hierarchy or above the file where the failure occurred. It is unspecified if $c p$ shall attempt to copy files below the file where the failure occurred (which cannot succeed in any case).
Permissions, owners, and groups of created special file types have been deliberately left as implementation-defined. This is to allow systems to satisfy special requirements (for example, allowing users to create character special devices, but requiring them to be owned by a certain group). In general, it is strongly suggested that the permissions, owner, and group be the same as if the user had run the historical mknod, ln, or other utility to create the file. It is also probable that additional privileges are required to create block, character, or other implementationdefined special file types.
Additionally, the -p option explicitly requires that all set-user-ID and set-group-ID permissions be discarded if any of the owner or group IDs cannot be set. This is to keep users from unintentionally giving away special privilege when copying programs.
When creating regular files, historical versions of $c p$ use the mode of the source file as modified by the file mode creation mask. Other choices would have been to use the mode of the source file unmodified by the creation mask or to use the same mode as would be given to a new file created by the user (plus the execution bits of the source file) and then modify it by the file mode creation mask. In the absence of any strong reason to change historic practice, it was in large part retained.

When creating directories, historical versions of $c p$ use the mode of the source directory, plus read, write, and search bits for the owner, as modified by the file mode creation mask. This is done so that $c p$ can copy trees where the user has read permission, but the owner does not. A side effect is that if the file creation mask denies the owner permissions, $c p$ fails. Also, once the copy is done, historical versions of $c p$ set the permissions on the created directory to be the same as the source directory, unmodified by the file creation mask.

This behavior has been modified so that $c p$ is always able to create the contents of the directory, regardless of the file creation mask. After the copy is done, the permissions are set to be the same as the source directory, as modified by the file creation mask. This latter change from historical behavior is to prevent users from accidentally creating directories with permissions beyond those they would normally set and for consistency with the behavior of $c p$ in creating files.
It is not a requirement that $c p$ detect attempts to copy a file to itself; however, implementations are strongly encouraged to do so. Historical implementations have detected the attempt in most cases.

There are two methods of copying subtrees in this volume of IEEE Std 1003.1-200x. The other method is described as part of the pax utility (see pax). Both methods are historical practice. The $c p$ utility provides a simpler, more intuitive interface, while pax offers a finer granularity of control. Each provides additional functionality to the other; in particular, pax maintains the hardlink structure of the hierarchy, while $c p$ does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.

The wording allowing $c p$ to copy a directory to implementation-defined file types not specified by the System Interfaces volume of IEEE Std 1003.1-200x is provided so that implementations supporting symbolic links are not required to prohibit copying directories to symbolic links. Other extensions to the System Interfaces volume of IEEE Std 1003.1-200x file types may need to use this loophole as well.

## FUTURE DIRECTIONS

The - $\mathbf{R}$ option should be used instead of the obsolescent -r option.

## CHANGE HISTORY

First released in Issue 2.

## Issue 6

The -r option is marked obsolescent.
The new options $-\mathbf{H},-\mathbf{L}$, and $-\mathbf{P}$ are added to align with the IEEE P1003.2b draft standard. These options affect the processing of symbolic links.
IEEE PASC Interpretation 1003.2 \#194 is applied, adding a description of the $\mathbf{- P}$ option.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/18 is applied, correcting an error in the SEE ALSO section.

Issue 7
SD5-XCU-ERN-31 and SD5-XCU-ERN-42 are applied, updating the DESCRIPTION.
The obsolescent -r option is removed.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-102 is applied, clarifying the $\mathbf{- i}$ option within the OPTIONS section.

| 10770 | NAME |  |
| :---: | :---: | :---: |
| 10771 | crontab - schedule periodic background work |  |
| 10772 | SYNOPSIS |  |
| 10773 |  | crontab [file] |
| 10774 | UP | crontab [-e $\|-1\|-r$ ] |
| 775 | DESCRIPTION |  |
| 10776 | UP | The crontab utility shall create, replace, or edit a user's crontab entry; a crontab entry is a list of commands and the times at which they shall be executed. The new crontab entry can be input by |
| 10777 |  |  |
| 10778 | UP | specifying file or input from standard input if no file operand is specified, or by using an editor, if -e is specified. |
| 10779 |  |  |
| 10780 |  | Upon execution of a command from a crontab entry, the implementation shall supply a default environment, defining at least the following environment variables: |
| 10781 |  |  |
| 10782 |  | HOME A pathname of the user's home directory. |
| 10783 |  | LOGNAME The user's login name. |
| 10784 |  | PATH A string representing a search path guaranteed to find all of the standard utilities. |
| 10785 |  | A pathname of the command interpreter. When crontab is invoked as specified by this volume of IEEE Std 1003.1-200x, the value shall be a pathname for sh. |
| 10786 |  |  |
| 10787 |  | The values of these variables when crontab is invoked as specified by this volume of IEEE Std 1003.1-200x shall not affect the default values provided when the scheduled command is run. |
| 10788 |  |  |
| 10789 |  |  |
| 10790 |  | If standard output and standard error are not redirected by commands executed from the crontab entry, any generated output or errors shall be mailed, via an implementation-defined method, to the user. |
| 10791 |  |  |
| 10792 |  |  |
| 10793 | XSI | Users shall be permitted to use crontab if their names appear in the file cron.allow which is located in an implementation-defined directory. If that file does not exist, the file cron.deny, which is located in an implementation-defined directory, shall be checked to determine whether the user shall be denied access to crontab. If neither file exists, only a process with appropriate privileges shall be allowed to submit a job. If only cron.deny exists and is empty, global usage shall be permitted. The cron.allow and cron.deny files shall consist of one user name per line. |
| 10794 |  |  |
| 10795 |  |  |
| 10796 |  |  |
| 10797 |  |  |
| 10798 |  |  |
| 10799 | OPTIONS |  |
| 10800 |  | The crontab utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. |
| 10801 |  |  |
| 10802 |  | The following options shall be supported: |
| 10803 | UP | -e Edit a copy of the invoking user's crontab entry, or create an empty entry to edit if |
| 10804 |  | the crontab entry does not exist. When editing is complete, the entry shall be |
| 10805 |  | installed as the user's crontab entry. |
| 10806 |  | -1 (The letter ell.) List the invoking user's crontab entry. |
| 10807 |  | -r Remove the invoking user's crontab entry. |
| 10808 | OPERANDS |  |
| 10809 |  | The following operand shall be supported: |
| 10810 |  | file The pathname of a file that contains specifications, in the format defined in the INPUT FILES section, for crontab entries. |

## STDIN

See the INPUT FILES section.

## INPUT FILES

In the POSIX locale, the user or application shall ensure that a crontab entry is a text file consisting of lines of six fields each. The fields shall be separated by <blank>s. The first five fields shall be integer patterns that specify the following:

1. Minute $[0,59]$
2. Hour $[0,23]$
3. Day of the month $[1,31]$
4. Month of the year $[1,12]$
5. Day of the week $([0,6]$ with $0=$ Sunday $)$

Each of these patterns can be either an asterisk (meaning all valid values), an element, or a list of elements separated by commas. An element shall be either a number or two numbers separated by a hyphen (meaning an inclusive range). The specification of days can be made by two fields (day of the month and day of the week). If month, day of month, and day of week are all asterisks, every day shall be matched. If either the month or day of month is specified as an element or list, but the day of week is an asterisk, the month and day of month fields shall specify the days that match. If both month and day of month are specified as an asterisk, but day of week is an element or list, then only the specified days of the week match. Finally, if either the month or day of month is specified as an element or list, and the day of week is also specified as an element or list, then any day matching either the month and day of month, or the day of week, shall be matched.
The sixth field of a line in a crontab entry is a string that shall be executed by sh at the specified times. A percent sign character in this field shall be translated to a <newline>. Any character preceded by a backslash (including the $\because \prime$ ) shall cause that character to be treated literally. Only the first line (up to a ' $\%$ ' or end-of-line) of the command field shall be executed by the command interpreter. The other lines shall be made available to the command as standard input. Blank lines and those whose first non-<blank> is '\#' shall be ignored.
xsi The text files cron.allow and cron.deny, which are located in an implementation-defined directory, shall contain zero or more user names, one per line, of users who are, respectively, authorized or denied access to the service underlying the crontab utility.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of crontab:
EDITOR Determine the editor to be invoked when the -e option is specified. The default editor shall be $v i$.
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

```
10856
10857

\section*{LC_MESSAGES}
```

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

```

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}
```

If the -1 option is specified, the crontab entry shall be written to the standard output.

```

\section*{STDERR}
```

The standard error shall be used only for diagnostic messages.

```

\section*{OUTPUT FILES}
```

None.

```

\section*{EXTENDED DESCRIPTION}
```

None.

```

\section*{EXIT STATUS}
```

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

```

\section*{CONSEQUENCES OF ERRORS}
```

UP The user's crontab entry is not submitted, removed, edited, or listed.

```

\section*{APPLICATION USAGE}
```

The format of the crontab entry shown here is guaranteed only for the POSIX locale. Other cultures may be supported with substantially different interfaces, although implementations are encouraged to provide comparable levels of functionality.
The default settings of the HOME, LOGNAME, PATH, and SHELL variables that are given to the scheduled job are not affected by the settings of those variables when crontab is run; as stated, they are defaults. The text about "invoked as specified by this volume of IEEE Std 1003.1-200x" means that the implementation may provide extensions that allow these variables to be affected at runtime, but that the user has to take explicit action in order to access the extension, such as give a new option flag or modify the format of the crontab entry.
A typical user error is to type only crontab; this causes the system to wait for the new crontab entry on standard input. If end-of-file is typed (generally <control>-D), the crontab entry is replaced by an empty file. In this case, the user should type the interrupt character, which prevents the crontab entry from being replaced.

```

\section*{EXAMPLES}
1. Clean up core files every weekday morning at 3:15 am:
```

15 3 * * 1-5 find \$HOME -name core 2>/dev/null | xargs rm -f

```
2. Mail a birthday greeting:
```

0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.

```
3. As an example of specifying the two types of days:
```

0 0 1,15 * 1

```
would run a command on the first and fifteenth of each month, as well as on every Monday. To specify days by only one field, the other field should be set to \({ }^{\prime} \star\) '; for example:

0 0 * * 1
would run a command only on Mondays.

\section*{RATIONALE}

All references to a cron daemon and to cron files have been omitted. Although historical implementations have used this arrangement, there is no reason to limit future implementations.

This description of crontab is designed to support only users with normal privileges. The format of the input is based on the System V crontab; however, there is no requirement here that the actual system database used by the cron daemon (or a similar mechanism) use this format internally. For example, systems derived from BSD are likely to have an additional field appended that indicates the user identity to be used when the job is submitted.
The -e option was adopted from the SVID as a user convenience, although it does not exist in all historical implementations.

\section*{FUTURE DIRECTIONS}

None.

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
The crontab utility (except for the - e option) is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-95 is applied, removing the references to fixed locations for the files referenced by the crontab utility.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
csplit - split files based on context

\section*{SYNOPSIS}
```

csplit [-ks] [-f prefix] [-n number] file argl ... argn

```

\section*{DESCRIPTION}

The csplit utility shall read the file named by the file operand, write all or part of that file into other files as directed by the arg operands, and write the sizes of the files.

\section*{OPTIONS}

The csplit utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-f prefix Name the created files prefix \(\mathbf{0 0}\), prefix \(\mathbf{0 1}, \ldots\), prefixn. The default is \(\mathbf{x x 0 0} \ldots \mathbf{x x} n\). If the prefix argument would create a filename exceeding \{NAME_MAX\} bytes, an error shall result, csplit shall exit with a diagnostic message, and no files shall be created.
-k Leave previously created files intact. By default, csplit shall remove created files if an error occurs.
-n number \(\begin{array}{ll} & \text { Us. } \\ & 2 .\end{array}\)
-s Suppress the output of file size messages.

\section*{OPERANDS}

The following operands shall be supported:
file The pathname of a text file to be split. If file is ' \(\quad\) ', the standard input shall be used.

The operands arg \(1 \ldots\) argn can be a combination of the following:
/rexp/[offset]
A file shall be created using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with offset, if any, applied. The regular expression rexp shall follow the rules for basic regular expressions described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. The application shall use the sequence " \(\backslash /\) " to specify a slash character within the rexp. The optional offset shall be a positive or negative integer value representing a number of lines. A positive integer value can be preceded by ' + '. If the selection of lines from an offset expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line shall be set to the line that results from the evaluation of the regular expression with any offset applied. If the current line is the first line in the file and a regular expression operation has not yet been performed, the pattern match of rexp shall be applied from the current line to the end of the file. Otherwise, the pattern match of rexp shall be applied from the line following the current line to the end of the file.
\%rexp\%[offset]
Equivalent to \(/ \mathrm{rexp} /[\) offset \(]\), except that no file shall be created for the selected section of the input file. The application shall use the sequence " \(\backslash \frac{}{\circ}\) " to specify a
percent-sign character within the rexp.
line_no Create a file from the current line up to (but not including) the line number line_no. Lines in the file shall be numbered starting at one. The current line becomes line_no.
\(\{n u m\} \quad\) Repeat operand. This operand can follow any of the operands described previously. If it follows a rexp type operand, that operand shall be applied num more times. If it follows a line_no operand, the file shall be split every line_no lines, num times, from that point.

An error shall be reported if an operand does not reference a line between the current position and the end of the file.

\section*{STDIN}

See the INPUT FILES section.

\section*{INPUT FILES}

The input file shall be a text file.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of csplit:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L \quad\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

If the \(-\mathbf{k}\) option is specified, created files shall be retained. Otherwise, the default action occurs.

\section*{STDOUT}

Unless the -s option is used, the standard output shall consist of one line per file created, with a format as follows:
"\%d\n", <file size in bytes>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

The output files shall contain portions of the original input file; otherwise, unchanged.

\section*{EXTENDED DESCRIPTION}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

By default, created files shall be removed if an error occurs. When the \(-\mathbf{k}\) option is specified, created files shall not be removed if an error occurs.

\section*{APPLICATION USAGE \\ None.}

\section*{EXAMPLES}
1. This example creates four files, cobol00 ... cobol03:
```

csplit -f cobol file '/procedure division/' /par5./ /par16./

```

After editing the split files, they can be recombined as follows:
```

cat cobol0[0-3] > file

```

Note that this example overwrites the original file.
2. This example would split the file after the first 99 lines, and every 100 lines thereafter, up to 9999 lines; this is because lines in the file are numbered from 1 rather than zero, for historical reasons:
csplit -k file 100 \{99\}
3. Assuming that prog.c follows the C-language coding convention of ending routines with \(\left.a^{\prime}\right\}^{\prime}\) at the beginning of the line, this example creates a file containing each separate \(C\) routine (up to 21) in prog.c:
csplit -k prog.c '\%main(\%' '/^\} \(/+1^{\prime}\{20\}\)

\section*{RATIONALE}

The - \(\mathbf{n}\) option was added to extend the range of filenames that could be handled.
Consideration was given to adding a -a flag to use the alphabetic filename generation used by the historical split utility, but the functionality added by the -n option was deemed to make alphabetic naming unnecessary.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO
sed, split

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
The description of regular expression operands is changed to align with the IEEE P1003.2b draft
standard.
The normative text is reworded to avoid use of the term "must" for application requirements.

\section*{Issue 7}

The csplit utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
ctags - create a tags file (DEVELOPMENT, FORTRAN)

\section*{SYNOPSIS}

SD
ctags [-a] [-f tagsfile] pathname...
ctags -x pathname...

\section*{DESCRIPTION}

The ctags utility shall be provided on systems that support the the Software Development Utilities option, and either or both of the C-Language Development Utilities option and FORTRAN Development Utilities option. On other systems, it is optional.
The ctags utility shall write a tagsfile or an index of objects from C-language or FORTRAN source files specified by the pathname operands. The tagsfile shall list the locators of language-specific objects within the source files. A locator consists of a name, pathname, and either a search pattern or a line number that can be used in searching for the object definition. The objects that shall be recognized are specified in the EXTENDED DESCRIPTION section.

\section*{OPTIONS}

The ctags utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a Append to tagsfile.
-f tagsfile Write the object locator lists into tagsfile instead of the default file named tags in the current directory.
-x Produce a list of object names, the line number, and filename in which each is defined, as well as the text of that line, and write this to the standard output. A tagsfile shall not be created when \(-\mathbf{x}\) is specified.

\section*{OPERANDS}

The following pathname operands are supported:
file.c Files with basenames ending with the .c suffix shall be treated as C-language source code. Such files that are not valid input to \(c 99\) produce unspecified results.
file.h Files with basenames ending with the .h suffix shall be treated as C-language source code. Such files that are not valid input to \(c 99\) produce unspecified results.
file.f Files with basenames ending with the .f suffix shall be treated as FORTRANlanguage source code. Such files that are not valid input to fort77 produce unspecified results.

The handling of other files is implementation-defined.

\section*{STDIN}

See the INPUT FILES section.

\section*{INPUT FILES}

The input files shall be text files containing source code in the language indicated by the operand filename suffixes.

\section*{ENVIRONMENT VARIABLES}

\section*{The following environment variables shall affect the execution of ctags:}

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the order in which output is sorted for the \(-\mathbf{x}\) option. The POSIX locale determines the order in which the tagsfile is written.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). When processing C-language source code, if the locale is not compatible with the C locale described by the ISO C standard, the results are unspecified.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The list of object name information produced by the \(-\mathbf{x}\) option shall be written to standard output in the following format:
"\%s \%d \%s \%s", <object-name>, <line-number>, <filename>, <text>
where <text> is the text of line <line-number> of file <filename>.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

When the \(\mathbf{- x}\) option is not specified, the format of the output file shall be:
"\%s \(\backslash t \% s \backslash t / \% s / \backslash n "\), <identifier>, <filename>, <pattern>
where <pattern> is a search pattern that could be used by an editor to find the defining instance of <identifier> in <filename> (where defining instance is indicated by the declarations listed in the EXTENDED DESCRIPTION).
An optional circumflex ( \({ }^{\prime}{ }^{\prime}\) ) can be added as a prefix to <pattern>, and an optional dollar sign can be appended to <pattern> to indicate that the pattern is anchored to the beginning (end) of a line of text. Any slash or backslash characters in <pattern> shall be preceded by a backslash character. The anchoring circumflex, dollar sign, and escaping backslash characters shall not be considered part of the search pattern. All other characters in the search pattern shall be considered literal characters.
An alternative format is:
"\%s\t\%s\t?\%s?\n", <identifier>, <filename>, <pattern>
which is identical to the first format except that slashes in <pattern> shall not be preceded by escaping backslash characters, and question mark characters in <pattern> shall be preceded by
backslash characters.
A second alternative format is:

where <lineno> is a decimal line number that could be used by an editor to find <identifier> in <filename>.
Neither alternative format shall be produced by ctags when it is used as described by IEEE Std 1003.1-200x, but the standard utilities that process tags files shall be able to process those formats as well as the first format.

In any of these formats, the file shall be sorted by identifier, based on the collation sequence in the POSIX locale.

\section*{EXTENDED DESCRIPTION}

If the operand identifies C-language source, the ctags utility shall attempt to produce an output line for each of the following objects:
- Function definitions
- Type definitions
- Macros with arguments

It may also produce output for any of the following objects:
- Function prototypes
- Structures
- Unions
- Global variable definitions
- Enumeration types
- Macros without arguments
- \#define statements
- \#line statements

Any \#if and \#ifdef statements shall produce no output. The tag main is treated specially in C programs. The tag formed shall be created by prefixing \(\mathbf{M}\) to the name of the file, with the trailing .c, and leading pathname components (if any) removed.
On systems that do not support the C-Language Development Utilities option, ctags produces unspecified results for C -language source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.
If the operand identifies FORTRAN source, the ctags utility shall produce an output line for each function definition. It may also produce output for any of the following objects:
- Subroutine definitions
- COMMON statements
- PARAMETER statements
- DATA and BLOCK DATA statements
- Statement numbers

On systems that do not support the FORTRAN Development Utilities option, ctags produces unspecified results for FORTRAN source code files. It should write to standard error a message identifying this condition and cause a non-zero exit status to be produced.

It is implementation-defined what other objects (including duplicate identifiers) produce output.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

The output with \(-\mathbf{x}\) is meant to be a simple index that can be written out as an off-line readable function index. If the input files to ctags (such as .c files) were not created using the same locale as that in effect when ctags \(-\mathbf{x}\) is run, results might not be as expected.
The description of C-language processing says "attempts to" because the C language can be greatly confused, especially through the use of \#defines, and this utility would be of no use if the real C preprocessor were run to identify them. The output from ctags may be fooled and incorrect for various constructs.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The option list was significantly reduced from that provided by historical implementations. The -F option was omitted as redundant, since it is the default. The -B option was omitted as being of very limited usefulness. The \(-\mathbf{t}\) option was omitted since the recognition of typedefs is now required for C source files. The -u option was omitted because the update function was judged to be not only inefficient, but also rarely needed.
An early proposal included a -w option to suppress warning diagnostics. Since the types of such diagnostics could not be described, the option was omitted as being not useful.
The text for LC_CTYPE about compatibility with the C locale acknowledges that the ISO C standard imposes requirements on the locale used to process C source. This could easily be a superset of that known as "the C locale" by way of implementation extensions, or one of a few alternative locales for systems supporting different codesets. No statement is made for FORTRAN because the ANSI X3.9-1978 standard (FORTRAN 77) does not (yet) define a similar locale concept. However, a general rule in this volume of IEEE Std 1003.1-200x is that any time that locales do not match (preparing a file for one locale and processing it in another), the results are suspect.
The collation sequence of the tags file is not affected by LC_COLLATE because it is typically not used by human readers, but only by programs such as \(v i\) to locate the tag within the source files. Using the POSIX locale eliminates some of the problems of coordinating locales between the ctags file creator and the vi file reader.
Historically, the tags file has been used only by \(e x\) and \(v i\). However, the format of the tags file has been published to encourage other programs to use the tags in new ways. The format allows either patterns or line numbers to find the identifiers because the historical vi recognizes either. The ctags utility does not produce the format using line numbers because it is not useful following any source file changes that add or delete lines. The documented search patterns match historical practice. It should be noted that literal leading circumflex or trailing dollar-sign characters in the search pattern will only behave correctly if anchored to the beginning of the line or end of the line by an additional circumflex or dollar-sign character.
Historical implementations also understand the objects used by the languages Pascal and sometimes LISP, and they understand the C source output by lex and yacc. The ctags utility is not required to accommodate these languages, although implementors are encouraged to do so.

The following historical option was not specified, as vgrind is not included in this volume of IEEE Std 1003.1-200x:
\(-\mathbf{v} \quad\) If the \(-\mathbf{v}\) flag is given, an index of the form expected by vgrind is produced on the standard output. This listing contains the function name, filename, and page number (assuming 64-line pages). Since the output is sorted into lexicographic order, it may be desired to run the output through sort -f. Sample use:
```

ctags -v files | sort -f > index vgrind -x index

```

The special treatment of the tag main makes the use of ctags practical in directories with more than one program.

\section*{FUTURE DIRECTIONS}

None.

\section*{CHANGE HISTORY}

First released in Issue 4.

\section*{Issue 5}

The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The OUTPUT FILES section is changed to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE PASC Interpretation 1003.2 \#168 is applied, changing "create" to "write" in the DESCRIPTION

Issue 7
The ctags utility is no longer dependent on support for the User Portability Utilities option.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

\section*{NAME}
cut - cut out selected fields of each line of a file

\section*{SYNOPSIS}
```

cut -b list [-n] [file...]
cut -c list [file...]
cut -f list [-d delim] [-s] [file...]

```

\section*{DESCRIPTION}

The cut utility shall cut out bytes ( \(-\mathbf{b}\) option), characters ( \(-\mathbf{c}\) option), or character-delimited fields (-f option) from each line in one or more files, concatenate them, and write them to standard output.

\section*{OPTIONS}

The cut utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The application shall ensure that the option-argument list (see options \(-\mathbf{b},-\mathbf{c}\), and \(-\mathbf{f}\) below) is a comma-separated list or <blank>-separated list of positive numbers and ranges. Ranges can be in three forms. The first is two positive numbers separated by a hyphen (low-high), which represents all fields from the first number to the second number. The second is a positive number preceded by a hyphen (-high), which represents all fields from field number 1 to that number. The third is a positive number followed by a hyphen (low-), which represents that number to the last field, inclusive. The elements in list can be repeated, can overlap, and can be specified in any order, but the bytes, characters, or fields selected shall be written in the order of the input data. If an element appears in the selection list more than once, it shall be written exactly once.
The following options shall be supported:
-b list Cut based on a list of bytes. Each selected byte shall be output unless the -n option is also specified. It shall not be an error to select bytes not present in the input line.
-c list Cut based on a list of characters. Each selected character shall be output. It shall not be an error to select characters not present in the input line.
-d delim Set the field delimiter to the character delim. The default is the <tab>.
-f list Cut based on a list of fields, assumed to be separated in the file by a delimiter character (see -d). Each selected field shall be output. Output fields shall be separated by a single occurrence of the field delimiter character. Lines with no field delimiters shall be passed through intact, unless -s is specified. It shall not be an error to select fields not present in the input line.
-n Do not split characters. When specified with the -b option, each element in list of the form low-high (hyphen-separated numbers) shall be modified as follows:
- If the byte selected by low is not the first byte of a character, low shall be decremented to select the first byte of the character originally selected by low. If the byte selected by high is not the last byte of a character, high shall be decremented to select the last byte of the character prior to the character originally selected by high, or zero if there is no prior character. If the resulting range element has high equal to zero or low greater than high, the list element shall be dropped from list for that input line without causing an error.

Each element in list of the form low- shall be treated as above with high set to the
number of bytes in the current line, not including the terminating <newline>. Each element in list of the form -high shall be treated as above with low set to 1 . Each element in list of the form num (a single number) shall be treated as above with low set to num and high set to num.
-s Suppress lines with no delimiter characters, when used with the -f option. Unless specified, lines with no delimiters shall be passed through untouched.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of an input file. If no file operands are specified, or if a file operand is ' - ' , the standard input shall be used.

\section*{STDIN}

The standard input shall be used only if no file operands are specified, or if a file operand is ' \(\quad\) '. See the INPUT FILES section.

\section*{INPUT FILES}

The input files shall be text files, except that line lengths shall be unlimited.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of cut:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The cut utility output shall be a concatenation of the selected bytes, characters, or fields (one of the following):
"\%s\n", <concatenation of bytes>
"\%s \(\backslash n\) ", <concatenation of characters>
"\%s\n", <concatenation of fields and field delimiters>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 All input files were output successfully.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

Earlier versions of the cut utility worked in an environment where bytes and characters were considered equivalent (modulo <backspace> and <tab> processing in some implementations). In the extended world of multi-byte characters, the new \(-\mathbf{b}\) option has been added. The \(-\mathbf{n}\) option (used with \(-\mathbf{b}\) ) allows it to be used to act on bytes rounded to character boundaries. The algorithm specified for \(\mathbf{- n}\) guarantees that:
```

cut -b 1-500 -n file > file1
cut -b 501- -n file > file2

```
ends up with all the characters in file appearing exactly once in file1 or file2. (There is, however, a <newline> in both file1 and file2 for each <newline> in file.)

\section*{EXAMPLES}

Examples of the option qualifier list:
1,4,7 Select the first, fourth, and seventh bytes, characters, or fields and field delimiters.
1-3,8 Equivalent to 1,2,3,8.
-5,10 Equivalent to 1,2,3,4,5,10.
3- Equivalent to third to last, inclusive.
The low-high forms are not always equivalent when used with -b and -n and multi-byte characters; see the description of \(\mathbf{- n}\).
The following command:
```

cut -d : -f 1,6/etc/passwd

```
reads the System V password file (user database) and produces lines of the form:
<user ID>:<home directory>
Most utilities in this volume of IEEE Std 1003.1-200x work on text files. The cut utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The paste utility can be used to create (or recreate) files with arbitrary line lengths. For example, if file contains long lines:
```

cut -b 1-500 -n file > file1
cut -b 501- -n file > file2

```
creates file1 (a text file) with lines no longer than 500 bytes (plus the <newline>) and file2 that contains the remainder of the data from file. (Note that file2 is not a text file if there are lines in file that are longer than \(500+\{\) LINE_MAX \(\}\) bytes.) The original file can be recreated from file 1 and file2 using the command:
```

paste -d "\0" file1 file2 > file

```

\section*{RATIONALE}

Some historical implementations do not count <backspace>s in determining character counts with the -c option. This may be useful for using cut for processing nroff output. It was deliberately decided not to have the - c option treat either <backspace>s or <tab>s in any special fashion. The fold utility does treat these characters specially.

Unlike other utilities, some historical implementations of cut exit after not finding an input file, rather than continuing to process the remaining file operands. This behavior is prohibited by this volume of IEEE Std 1003.1-200x, where only the exit status is affected by this problem.

The behavior of cut when provided with either mutually-exclusive options or options that do not work logically together has been deliberately left unspecified in favor of global wording in Section 1.11 (on page 18).
The OPTIONS section was changed in response to IEEE PASC Interpretation 1003.2 \#149. The change represents historical practice on all known systems. The original standard was ambiguous on the nature of the output.
The list option-arguments are historically used to select the portions of the line to be written, but do not affect the order of the data. For example:
```

echo abcdefghi | cut -c6,2,4-7,1

```
yields "abdefg".
A proposal to enhance cut with the following option:
-o Preserve the selected field order. When this option is specified, each byte, character, or field (or ranges of such) shall be written in the order specified by the list option-argument, even if this requires multiple outputs of the same bytes, characters, or fields.
was rejected because this type of enhancement is outside the scope of the IEEE P1003.2b draft standard.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO
grep, paste, Section 2.5

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
The OPTIONS section is changed to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
cxref - generate a C-language program cross-reference table (DEVELOPMENT)

\section*{SYNOPSIS}
xsi cxref [-cs] [-o file] [-w num] [-D name[=def]]... [-I dir]...
[-U name]... file...

\section*{DESCRIPTION}

The cxref utility shall analyze a collection of C-language files and attempt to build a crossreference table. Information from \#define lines shall be included in the symbol table. A sorted listing shall be written to standard output of all symbols (auto, static, and global) in each file separately, or with the -c option, in combination. Each symbol shall contain an asterisk before the declaring reference.

\section*{OPTIONS}

The cxref utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the \(-\mathbf{D}, \mathbf{I}\), and \(-\mathbf{U}\) options (which are identical to their interpretation by \(c 99\) ) is significant. The following options shall be supported:
-c Write a combined cross-reference of all input files.
-s Operate silently; do not print input filenames.
-o file Direct output to named file.
-w num Format output no wider than num (decimal) columns. This option defaults to 80 if num is not specified or is less than 51.
-D Equivalent to c99.
-I Equivalent to c99.
-U Equivalent to c99.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a C-language source file.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

The input files are C-language source files.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of cxref:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for the ordering of the output.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of \(L C\) _MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The standard output shall be used for the cross-reference listing, unless the - ooption is used to select a different output file.
The format of standard output is unspecified, except that the following information shall be included:
- If the -c option is not specified, each portion of the listing shall start with the name of the input file on a separate line.
- The name line shall be followed by a sorted list of symbols, each with its associated location pathname, the name of the function in which it appears (if it is not a function name itself), and line number references.
- Each line number may be preceded by an asterisk ( \({ }^{*}{ }^{\prime}\) ) flag, meaning that this is the declaring reference. Other single-character flags, with implementation-defined meanings, may be included.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

The output file named by the -o option shall be used instead of standard output.

\section*{EXTENDED DESCRIPTION}

None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\%Ec Locale's alternative appropriate date and time representation.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of date:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME Determine the format and contents of date and time strings written by date.
XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

TZ Determine the timezone in which the time and date are written, unless the \(-\mathbf{u}\) option is specified. If the \(T Z\) variable is unset or null and \(-\mathbf{u}\) is not specified, an unspecified system default timezone is used.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

When no formatting operand is specified, the output in the POSIX locale shall be equivalent to specifying:
```

date "+%a %b %e %H:%M:%S %Z %Y"

```

STDERR
The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 The date was written successfully.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

Conversion specifiers are of unspecified format when not in the POSIX locale. Some of them can contain <newline>s in some locales, so it may be difficult to use the format shown in standard output for parsing the output of date in those locales.
The range of values for \(\%\) S extends from 0 to 60 seconds to accommodate the occasional leap second.

Although certain of the conversion specifiers in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these fields may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.
The date string formatting capabilities are intended for use in Gregorian-style calendars, possibly with a different starting year (or years). The \%x and \%c conversion specifications, however, are intended for local representation; these may be based on a different, non-Gregorian calendar.

The \%C conversion specification was introduced to allow a fallback for the \%EC (alternative year format base year); it can be viewed as the base of the current subdivision in the Gregorian calendar. The century number is calculated as the year divided by 100 and truncated to an integer; it should not be confused with the use of ordinal numbers for centuries (for example, "twenty-first century".) Both the \(\% \mathrm{Ey}\) and \(\% \mathrm{y}\) can then be viewed as the offset from \(\% \mathrm{EC}\) and \(\% \mathrm{C}\), respectively.

The E and O modifiers modify the traditional conversion specifiers, so that they can always be used, even if the implementation (or the current locale) does not support the modifier.
The E modifier supports alternative date formats, such as the Japanese Emperor's Era, as long as these are based on the Gregorian calendar system. Extending the E modifiers to other date elements may provide an implementation-defined extension capable of supporting other calendar systems, especially in combination with the omodifier.
The o modifier supports time and date formats using the locale's alternative numerical symbols, such as Kanji or Hindi digits or ordinal number representation.

Non-European locales, whether they use Latin digits in computational items or not, often have local forms of the digits for use in date formats. This is not totally unknown even in Europe; a variant of dates uses Roman numerals for the months: the third day of September 1991 would be written as 3.IX.1991. In Japan, Kanji digits are regularly used for dates; in Arabic-speaking countries, Hindi digits are used. The \(\% \mathrm{~d}, \% \mathrm{e} \% \mathrm{H}, \% \mathrm{I}, \% \mathrm{~m}, \% \mathrm{~S}, \% \mathrm{U}, \% \mathrm{w}, \% \mathrm{~W}\), and \(\% \mathrm{y}\) conversion specifications always return the date and time field in Latin digits (that is, 0 to 9 ). The \%o modifier was introduced to support the use for display purposes of non-Latin digits. In the LC_TIME category in localedef, the optional alt_digits keyword is intended for this purpose. As an example, assume the following (partial) localedef source:
```

alt_digits "";"I";"II";"III";"IV";"V";"VI";"VII";"VIII" \
"IX";"X";"XI";"XII"
d_fmt "%e.%Om.%Y"

```

With the above date, the command:
```

date "+%x"

```
would yield 3.IX.1991. With the same d_fmt, but without the alt_digits, the command would yield 3.9.1991.

\section*{EXAMPLES}
1. The following are input/output examples of date used at arbitrary times in the POSIX locale:
```

\$ date
Tue Jun 26 09:58:10 PDT 1990
\$ date "+DATE: %m/%d/%y%nTIME: %H:%M:%S"
DATE: 11/02/91
TIME: 13:36:16
\$ date "+TIME: %r"
TIME: 01:36:32 PM

```
2. Examples for Denmark, where the default date and time format is \(\% a \% d \% b \% Y \% T \% Z\) :
```

\$ LANG=da_DK.iso_8859-1 date
ons 02 okt 1991 15:03:32 CET
\$ LANG=da_DK.iso_8859-1 \
date "+DATO: %A den %e. %B %Y%nKLOKKEN: %H:%M:%S"
DATO: onsdag den 2. oktober 1991
KLOKKEN: 15:03:56

```
3. Examples for Germany, where the default date and time format is \(\% \mathrm{a} \% \mathrm{~d} . \% \mathrm{~h} . \% \mathrm{Y}, \% \mathrm{~T} \% \mathrm{Z}\) :
```

\$ LANG=De_DE.88591 date
Mi 02.Okt.1991, 15:01:21 MEZ

```
\$ LANG=De_DE. 88591 date "+DATUM: \%A, \%d. \%B \%Y \%nZEIT: \%H: \%M: \%S"
DATUM: Mittwoch, 02. Oktober 1991
ZEIT: 15:02:02
4. Examples for France, where the default date and time format is \(\% \mathrm{a} \% \mathrm{~d} \% \mathrm{~h} \% \mathrm{Y} \% \mathrm{Z} \% \mathrm{~T}\) :
```

\$ LANG=Fr_FR. }88591\mathrm{ date
Mer 02 oct 1991 MET 15:03:32
\$ LANG=Fr_FR.88591 date "+JOUR: %A %d %B %Y%nHEURE: %H:%M:%S"
JOUR: Mercredi 02 octobre 1991
HEURE: 15:03:56

```

\section*{RATIONALE}

Some of the new options for formatting are from the ISO C standard. The \(-\mathbf{u}\) option was introduced to allow portable access to Coordinated Universal Time (UTC). The string "GMT0" is allowed as an equivalent \(T Z\) value to be compatible with all of the systems using the BSD implementation, where this option originated.
The \%e format conversion specification (adopted from System V) was added because the ISO C standard conversion specifications did not provide any way to produce the historical default date output during the first nine days of any month.

There are two varieties of day and week numbering supported (in addition to any others created with the locale-dependent \(\% \mathrm{E}\) and \(\% \mathrm{O}\) modifier characters):
- The historical variety in which Sunday is the first day of the week and the weekdays preceding the first Sunday of the year are considered week 0 . These are represented by \(\% \mathrm{w}\) and \(\% \mathrm{U}\). A variant of this is \(\% \mathrm{~W}\), using Monday as the first day of the week, but still referring to week 0 . This view of the calendar was retained because so many historical applications depend on it and the ISO C standard strftime( ) function, on which many date implementations are based, was defined in this way.
- The international standard, based on the ISO 8601:2000 standard where Monday is the first weekday and the algorithm for the first week number is more complex: If the week (Monday to Sunday) containing January 1 has four or more days in the new year, then it is week 1; otherwise, it is week 53 of the previous year, and the next week is week 1 . These are represented by the new conversion specifications \(\% u\) and \(\% \mathrm{~V}\), added as a result of international comments.

\section*{FUTURE DIRECTIONS}

None.

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
Changes are made for Year 2000 alignment.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The \%EX modified conversion specification is added.

The Open Group Corrigendum U048/2 is applied, correcting the examples.
The DESCRIPTION is updated to refer to conversion specifications, instead of field descriptors for consistency with the LC_TIME category.
A clarification is made such that the current year is the default if the \(y y\) argument is omitted when setting the system date and time.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/19 is applied, correcting the CHANGE HISTORY section.

\section*{NAME}
dd - convert and copy a file

\section*{SYNOPSIS}
```

dd [operand...]

```

\section*{DESCRIPTION}

The \(d d\) utility shall copy the specified input file to the specified output file with possible conversions using specific input and output block sizes. It shall read the input one block at a time, using the specified input block size; it shall then process the block of data actually returned, which could be smaller than the requested block size. It shall apply any conversions that have been specified and write the resulting data to the output in blocks of the specified output block size. If the \(\mathbf{b s}=\) expr operand is specified and no conversions other than sync, noerror, or notrunc are requested, the data returned from each input block shall be written as a separate output block; if the read returns less than a full block and the sync conversion is not specified, the resulting output block shall be the same size as the input block. If the bs=expr operand is not specified, or a conversion other than sync, noerror, or notrunc is requested, the input shall be processed and collected into full-sized output blocks until the end of the input is reached.

The processing order shall be as follows:
1. An input block is read.
2. If the input block is shorter than the specified input block size and the sync conversion is specified, null bytes shall be appended to the input data up to the specified size. (If either block or unblock is also specified, <space>s shall be appended instead of null bytes.) The remaining conversions and output shall include the pad characters as if they had been read from the input.
3. If the \(\mathbf{b s}=\operatorname{expr}\) operand is specified and no conversion other than sync or noerror is requested, the resulting data shall be written to the output as a single block, and the remaining steps are omitted.
4. If the swab conversion is specified, each pair of input data bytes shall be swapped. If there is an odd number of bytes in the input block, the last byte in the input record shall not be swapped.
5. Any remaining conversions (block, unblock, lcase, and ucase) shall be performed. These conversions shall operate on the input data independently of the input blocking; an input or output fixed-length record may span block boundaries.
6. The data resulting from input or conversion or both shall be aggregated into output blocks of the specified size. After the end of input is reached, any remaining output shall be written as a block without padding if conv=sync is not specified; thus, the final output block may be shorter than the output block size.

\section*{OPTIONS}

None.

\section*{OPERANDS}

All of the operands shall be processed before any input is read. The following operands shall be supported:
\(\mathbf{i f}=\) file
Specify the input pathname; the default is standard input.

The behavior is unspecified if operands other than conv= are specified more than once.
For the \(\mathbf{b s}=\), \(\mathbf{c b s}=\), \(\mathbf{i b s}=\), and \(\mathbf{o b s}=\) operands, the application shall supply an expression specifying a size in bytes. The expression, expr, can be:
1. A positive decimal number
2. A positive decimal number followed by \(k\), specifying multiplication by 1024
3. A positive decimal number followed by \(b\), specifying multiplication by 512
4. Two or more positive decimal numbers (with or without \(k\) or \(b\) ) separated by \(x\), specifying the product of the indicated values
All of the operands are processed before any input is read.
xSI The following two tables display the octal number character values used for the ascii and ebcdic conversions (first table) and for the ibm conversion (second table). In both tables, the ASCII values are the row and column headers and the EBCDIC values are found at their intersections. For example, ASCII 0012 (LF) is the second row, third column, yielding 0045 in EBCDIC. The inverted tables (for EBCDIC to ASCII conversion) are not shown, but are in one-to-one correspondence with these tables. The differences between the two tables are highlighted by

\hline
\end{tabular}

\section*{INPUT FILES}

The input file can be any file type.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(d d\) :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the classification of characters as uppercase or lowercase, and the mapping of characters from one case to the other.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

For SIGINT, the \(d d\) utility shall interrupt its current processing, write status information to standard error, and exit as though terminated by SIGINT. It shall take the standard action for all other signals; see the ASYNCHRONOUS EVENTS section in Section 1.11 (on page 18).

\section*{STDOUT}

If no of= operand is specified, the standard output shall be used. The nature of the output depends on the operands selected.

\section*{STDERR}

On completion, \(d d\) shall write the number of input and output blocks to standard error. In the POSIX locale the following formats shall be used:
```

"%u+%u records in\n", <number of whole input blocks>,
<number of partial input blocks>
"%u+%u records out\n", <number of whole output blocks>,
<number of partial output blocks>

```

A partial input block is one for which read() returned less than the input block size. A partial output block is one that was written with fewer bytes than specified by the output block size.
In addition, when there is at least one truncated block, the number of truncated blocks shall be written to standard error. In the POSIX locale, the format shall be:
```

"%u truncated %s\n", <number of truncated blocks>, "record" (if
<number of truncated blocks> is one) "records" (otherwise)

```

Diagnostic messages may also be written to standard error.

\section*{OUTPUT FILES}

If the of= operand is used, the output shall be the same as described in the STDOUT section.

\section*{EXTENDED DESCRIPTION}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 The input file was copied successfully.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

If an input error is detected and the noerror conversion has not been specified, any partial output block shall be written to the output file, a diagnostic message shall be written, and the copy operation shall be discontinued. If some other error is detected, a diagnostic message shall be written and the copy operation shall be discontinued.

\section*{APPLICATION USAGE}

The input and output block size can be specified to take advantage of raw physical I/O.
There are many different versions of the EBCDIC codesets. The ASCII and EBCDIC conversions specified for the \(d d\) utility perform conversions for the version specified by the tables.

\section*{EXAMPLES}

The following command:
dd if=/dev/rmt0h of=/dev/rmtin
copies from tape drive 0 to tape drive 1 , using a common historical device naming convention.
The following command:
dd ibs=10 skip=1
strips the first 10 bytes from standard input.
This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file \(\mathbf{x}\) :
dd if=/dev/tape \(0 \mathrm{f}=\mathrm{x}\) ibs=800 cbs=80 conv=ascii,lcase

\section*{RATIONALE}

The OPTIONS section is listed as "None" because there are no options recognized by historical \(d d\) utilities. Certainly, many of the operands could have been designed to use the Utility Syntax Guidelines, which would have resulted in the classic hyphenated option letters. In this version of this volume of IEEE Std 1003.1-200x, dd retains its curious JCL-like syntax due to the large number of applications that depend on the historical implementation.
A suggested implementation technique for conv=noerror,sync is to zero (or <space>-fill, if blocking or unblocking) the input buffer before each read and to write the contents of the input buffer to the output even after an error. In this manner, any data transferred to the input buffer before the error was detected is preserved. Another point is that a failed read on a regular file or a disk generally does not increment the file offset, and \(d d\) must then seek past the block on which the error occurred; otherwise, the input error occurs repetitively. When the input is a magnetic tape, however, the tape normally has passed the block containing the error when the error is reported, and thus no seek is necessary.
The default ibs= and obs= sizes are specified as 512 bytes because there are historical (largely portable) scripts that assume these values. If they were left unspecified, unusual results could occur if an implementation chose an odd block size.
Historical implementations of \(d d\) used \(\operatorname{creat()}\) when processing of=file. This makes the seek= operand unusable except on special files. The conv=notrunc feature was added because more recent BSD-based implementations use open() (without O_TRUNC) instead of creat (), but they
fail to delete output file contents after the data copied.
The \(w\) multiplier (historically meaning word), is used in System V to mean 2 and in 4.2 BSD to mean 4. Since word is inherently non-portable, its use is not supported by this volume of IEEE Std 1003.1-200x.

Standard EBCDIC does not have the characters ' [' and ' ]'. The values used in the table are taken from a common print train that does contain them. Other than those characters, the print train values are not filled in, but appear to provide some of the motivation for the historical choice of translations reflected here.

The Standard EBCDIC table provides a 1:1 translation for all 256 bytes.
The IBM EBCDIC table does not provide such a translation. The marked cells in the tables differ in such a way that:
1. EBCDIC 0112 ( \(\left.\prime^{\prime} \xi^{\prime}\right)\) and 0152 (broken pipe) do not appear in the table.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
The second paragraph of the \(\mathbf{c b s}=\) description is reworded and marked EX.
The FUTURE DIRECTIONS section is added.
Issue 6
Changes are made to swab conversion and SIGINT handling to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE PASC Interpretation 1003.2 \#209 is applied, clarifying the interaction between \(d d\) of=file and conv=notrunc.

Issue 7
Austin Group Interpretation 1003.1-2001 \#102 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
delta - make a delta (change) to an SCCS file (DEVELOPMENT)

\section*{SYNOPSIS}
xSI delta [-nps] [-g list] [-m mrlist] [-r SID] [-y[comment]] file...

\section*{DESCRIPTION}

The delta utility shall be used to permanently introduce into the named SCCS files changes that were made to the files retrieved by get (called the \(g\)-files, or generated files).

\section*{OPTIONS}

The delta utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the \(-\mathbf{y}\) option has an optional option-argument. This optional option-argument shall not be presented as a separate argument.
The following options shall be supported:
\(-\mathbf{r}\) SID Uniquely identify which delta is to be made to the SCCS file. The use of this option shall be necessary only if two or more outstanding get commands for editing (get \(-\mathbf{e}\) ) on the same SCCS file were done by the same person (login name). The SID value specified with the -r option can be either the SID specified on the get command line or the SID to be made as reported by the get utility; see get (on page 476).
-s Suppress the report to standard output of the activity associated with each file. See the STDOUT section.
-n Specify retention of the edited \(g\)-file (normally removed at completion of delta processing).
- \(\mathbf{g}\) list \(\quad\) Specify a list (see get for the definition of list) of deltas that shall be ignored when the file is accessed at the change level (SID) created by this delta.
\(-\mathbf{m}\) mrlist \(\quad\) Specify a modification request (MR) number that the application shall supply as the reason for creating the new delta. This shall be used if the SCCS file has the \(\mathbf{v}\) flag set; see admin .

If \(\mathbf{- m}\) is not used and \({ }^{\prime}-{ }^{\prime}\) is not specified as a file argument, and the standard input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued.
MRs in a list shall be separated by <blank>s or escaped <newline>s. An unescaped <newline> shall terminate the MR list. The escape character is <backslash>.

If the \(\mathbf{v}\) flag has a value, it shall be taken to be the name of a program which validates the correctness of the MR numbers. If a non-zero exit status is returned from the MR number validation program, the delta utility shall terminate. (It is assumed that the MR numbers were not all valid.)
\(-\mathbf{y}\) [comment] Describe the reason for making the delta. The comment shall be an arbitrary group of lines that would meet the definition of a text file. Implementations shall support comments from zero to 512 bytes and may support longer values. A null string (specified as either \(-\mathbf{y},-\mathbf{y}^{\prime \prime}\) ", or in response to a prompt for a comment) shall be considered a valid comment.
If \(-\mathbf{y}\) is not specified and \({ }^{\prime} \mathbf{'}^{\prime}\) is not specified as a file argument, and the standard
input is a terminal, the prompt described in the STDOUT section shall be written to standard output before the standard input is read; if the standard input is not a terminal, no prompt shall be issued. An unescaped <newline> shall terminate the comment text. The escape character is <backslash>.
The \(-\mathbf{y}\) option shall be required if the file operand is specified as ' - '.
-p Write (to standard output) the SCCS file differences before and after the delta is applied in diff format; see diff.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the delta utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with \(\mathbf{s}\).) and unreadable files shall be silently ignored.
If exactly one file operand appears, and it is ' - ', the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

\section*{STDIN}

The standard input shall be a text file used only in the following cases:
- To read an mrlist or a comment (see the \(-\mathbf{m}\) and \(-\mathbf{y}\) options).
- A file operand shall be specified as '- . In this case, the \(-\mathbf{y}\) option must be used to specify the comment, and if the SCCS file has the \(\mathbf{v}\) flag set, the \(-\mathbf{m}\) option must also be used to specify the MR list.

\section*{INPUT FILES}

Input files shall be text files whose data is to be included in the SCCS files. If the first character of any line of an input file is <SOH> in the POSIX locale, the results are unspecified. If this file contains more than 99999 lines, the number of lines recorded in the header for this file shall be 99999 for this delta.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of delta:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
\(T Z \quad\) Determine the timezone in which the time and date are written in the SCCS file. If the \(T Z\) variable is unset or NULL, an unspecified system default timezone is used.

\section*{ASYNCHRONOUS EVENTS}

If SIGINT is caught, temporary files shall be cleaned up and delta shall exit with a non-zero exit code. The standard action shall be taken for all other signals; see Section 1.11 (on page 18).

\section*{STDOUT}

The standard output shall be used only for the following messages in the POSIX locale:
- Prompts (see the \(-\mathbf{m}\) and \(-\mathbf{y}\) options) in the following formats:
"MRs? "
"comments? "
The MR prompt, if written, shall always precede the comments prompt.
- A report of each file's activities (unless the -s option is specified) in the following format:
```

"%s\n%d inserted\n%d deleted\n%d unchanged\n", <New SID>,
<number of lines inserted>, <number of lines deleted>,
<number of lines unchanged>

```

STDERR
The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

Any SCCS files updated shall be files of an unspecified format.

\section*{EXTENDED DESCRIPTION}

\section*{System Date and Time}

When a delta is added to an SCCS file, the system date and time shall be recorded for the new delta. If a get is performed using an SCCS file with a date recorded apparently in the future, the behavior is unspecified.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

Problems can arise if the system date and time have been modified (for example, put forward and then back again, or unsynchronized clocks across a network) and can also arise when different values of the \(T Z\) environment variable are used.
Problems of a similar nature can also arise for the operation of the get utility, which records the date and time in the file body.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

None.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}

Section 1.11 (on page 18), admin, diff, get , prs, rmdel

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
The output format description in the STDOUT section is corrected.
Issue 6
The APPLICATION USAGE section is added.
The normative text is reworded to avoid use of the term "must" for application requirements.
The Open Group Base Resolution bwg2001-007 is applied as follows:
- The use of ' \(\quad\) ' as a file argument is clarified.
- The use of STDIN is added.
- The ASYNCHRONOUS EVENTS section is updated to remove the implicit requirement that implementations re-signal themselves when catching a normally fatal signal.
- New text is added to the INPUT FILES section warning that the maximum lines recorded in the file is 99999.

New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections regarding how the system date and time may be taken into account, and the \(T Z\) environment variable is added to the ENVIRONMENT VARIABLES section as per The Open Group Base Resolution bwg2001-007.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

The \(d f\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-k Use 1024-byte units, instead of the default 512-byte units, when writing space figures.
-P Produce output in the format described in the STDOUT section.
XSI -t Include total allocated-space figures in the output.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a file within the hierarchy of the desired file system. If a file other than a FIFO, a regular file, a directory, or a special file representing the device containing the file system (for example, /dev/dsk/0s1) is specified, the results are unspecified. If the file operand names a file other than a special file containing a file system, \(d f\) shall write the amount of free space in the file system containing the specified file operand. Otherwise, \(d f\) shall write the amount of free space in that file system.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

None.

The following environment variables shall affect the execution of \(d f\) :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables. characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xSi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

When both the \(\mathbf{- k}\) and \(\mathbf{- P}\) options are specified, the following header line shall be written (in the POSIX locale):
"Filesystem 1024-blocks Used Available Capacity Mounted on\n"
When the \(-\mathbf{P}\) option is specified without the \(-\mathbf{k}\) option, the following header line shall be written (in the POSIX locale):
```

"Filesystem 512-blocks Used Available Capacity Mounted on\n"

```

The implementation may adjust the spacing of the header line and the individual data lines so that the information is presented in orderly columns.
The remaining output with \(-\mathbf{P}\) shall consist of one line of information for each specified file system. These lines shall be formatted as follows:
```

"%s %d %d %d %d%% %s\n", <file system name>, <total space>,
<space used>, <space free>, <percentage used>,
<file system root>

```

In the following list, all quantities expressed in 512-byte units (1024-byte when \(-\mathbf{k}\) is specified) shall be rounded up to the next higher unit. The fields are:
<file system name>
The name of the file system, in an implementation-defined format.
<total space> The total size of the file system in 512-byte units. The exact meaning of this figure is implementation-defined, but should include <space used>, <space free>, plus any space reserved by the system not normally available to a user.
<space used> The total amount of space allocated to existing files in the file system, in 512-byte units.
<space free> The total amount of space available within the file system for the creation of new files by unprivileged users, in 512-byte units. When this figure is less than or equal to zero, it shall not be possible to create any new files on the file system without first deleting others, unless the process has appropriate privileges. The figure written may be less than zero.
<percentage used>
The percentage of the normally available space that is currently allocated to all files on the file system. This shall be calculated using the fraction:
```

<space used>/( <space used>+ <space free>)

```
expressed as a percentage. This percentage may be greater than 100 if <space free> is less than zero. The percentage value shall be expressed as a positive integer, with any fractional result causing it to be rounded to the next highest integer.
<file system root>
The directory below which the file system hierarchy appears.

XSI The output format is unspecified when \(-\mathbf{t}\) is used.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

On most systems, the "name of the file system, in an implementation-defined format" is the special file on which the file system is mounted.

On large file systems, the calculation specified for percentage used can create huge rounding errors.

\section*{EXAMPLES}
1. The following example writes portable information about the /usr file system:
df -P /usr
2. Assuming that /usr/src is part of the /usr file system, the following produces the same output as the previous example:
df -P /usr/src

\section*{RATIONALE}

The behavior of \(d f\) with the \(-\mathbf{P}\) option is the default action of the 4.2 BSD \(d f\) utility. The uppercase \(-\mathbf{P}\) was selected to avoid collision with a known industry extension using -p.
Historical df implementations vary considerably in their default output. It was therefore necessary to describe the default output in a loose manner to accommodate all known historical implementations and to add a portable option \((-\mathbf{P})\) to provide information in a portable format.
The use of 512-byte units is historical practice and maintains compatibility with \(l s\) and other utilities in this volume of IEEE Std 1003.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The \(-\mathbf{k}\) option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (versus the mixed 512/1024-byte usage on BSD systems), and that a \(-\mathbf{k}\) option to switch to 1024 -byte units was a good compromise. Users who prefer the more logical 1024-byte quantity can easily alias \(d f\) to \(d f-\mathbf{k}\) without breaking many historical scripts relying on the 512-byte units.
It was suggested that \(d f\) and the various related utilities be modified to access a BLOCKSIZE environment variable to achieve consistency and user acceptance. Since this is not historical practice on any system, it is left as a possible area for system extensions and will be re-evaluated in a future version if it is widely implemented.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
find

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
Issue 7
Austin Group Interpretation 1003.1-2001 \#099 is applied.
The \(d f\) utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
diff - compare two files

\section*{SYNOPSIS}
diff [-c|-e|-f|-u|-C n|-U n] [-br] file1 file2

\section*{DESCRIPTION}

The diff utility shall compare the contents of file1 and file2 and write to standard output a list of changes necessary to convert file1 into file2. This list should be minimal. No output shall be produced if the files are identical.

\section*{OPTIONS}

The diff utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
\begin{tabular}{|c|c|}
\hline -b & Cause any amount of white space at the end of a line to be treated as a single <newline> (that is, the white-space characters preceding the <newline> are ignored) and other strings of white-space characters, not including <newline>s, to compare equal. \\
\hline -C & Produce output in a form that provides three lines of copied context. \\
\hline -C \(n\) & Produce output in a form that provides \(n\) lines of copied context (where \(n\) shall be interpreted as a positive decimal integer). \\
\hline -e & Produce output in a form suitable as input for the ed utility, which can then be used to convert file1 into file2. \\
\hline -f & Produce output in an alternative form, similar in format to - \(\mathbf{e}\), but not intended to be suitable as input for the ed utility, and in the opposite order. \\
\hline & \begin{tabular}{l}
Apply diff recursively to files and directories of the same name when file1 and file2 are both directories. \\
The diff utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, diff shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.
\end{tabular} \\
\hline -u & Produce output in a form that provides three lines of unified context. \\
\hline - \(\mathbf{U} n\) & Produce output in a form that provides \(n\) lines of unified context (where \(n\) shall be interpreted as a non-negative decimal integer). \\
\hline
\end{tabular}

\section*{OPERANDS}

The following operands shall be supported:
file1, file2 A pathname of a file to be compared. If either the file1 or file2 operand is ' - ', the standard input shall be used in its place.

If both file1 and file2 are directories, diff shall not compare block special files, character special files, or FIFO special files to any files and shall not compare regular files to directories. Further details are as specified in Diff Directory Comparison Format (on page 319). The behavior of diff on other file types is implementation-defined when found in directories.
If only one of file1 and file2 is a directory, diff shall be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the nondirectory file.

\section*{STDIN}

The standard input shall be used only if one of the file1 or file2 operands references standard input. See the INPUT FILES section.

\section*{INPUT FILES}

The input files may be of any type.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of diff:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

\section*{LC_MESSAGES}

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LC_TIME Determine the locale for affecting the format of file timestamps written with the -C and -c options.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
\(T Z \quad\) Determine the timezone used for calculating file timestamps written with a context format. If \(T Z\) is unset or null, an unspecified default timezone shall be used.

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

\section*{Diff Directory Comparison Format}

If both file1 and file2 are directories, the following output formats shall be used.
In the POSIX locale, each file that is present in only one directory shall be reported using the following format:
"Only in \%s: \%s\n", <directory pathname>, <filename>
In the POSIX locale, subdirectories that are common to the two directories may be reported with the following format:
```

"Common subdirectories: %s and %s\n", <directoryl pathname>,
<directory2 pathname>

```

For each file common to the two directories, if the two files are not to be compared: if the two files have the same device ID and file serial number, or are both block special files that refer to the same device, or are both character special files that refer to the same device, in the POSIX locale the output format is unspecified. Otherwise, in the POSIX locale an unspecified format shall be used that contains the pathnames of the two files.
For each file common to the two directories, if the files are compared and are identical, no output shall be written. If the two files differ, the following format is written:
"diff \%s \%s \%s\n", <diff_options>, <filename1>, <filename2>
where <diff_options> are the options as specified on the command line.
All directory pathnames listed in this section shall be relative to the original command line arguments. All other names of files listed in this section shall be filenames (pathname components).

\section*{Diff Binary Output Format}

In the POSIX locale, if one or both of the files being compared are not text files, an unspecified format shall be used that contains the pathnames of two files being compared and the string "differ".
If both files being compared are text files, depending on the options specified, one of the following formats shall be used to write the differences.

\section*{Diff Default Output Format}

The default (without \(-\mathbf{e},-\mathbf{f},-\mathbf{c},-\mathbf{C},-\mathbf{u}\), or \(-\mathbf{U}\) options) diff utility output shall contain lines of these forms:
```

"%da%d\n", <num1>, <num2>
"%da%d,%d\n", <num1>, <num2>, <num3>
"%dd%d\n", <num1>, <num2>
"%d,%dd%d\n", <num1>, <num2>, <num3>
"%dc%d\n", <num1>, <num2>
"%d,%dc%d\n", <num1>, <num2>, <num3>
"%dc%d,%d\n", <num1>, <num2>, <num3>
"%d,%dc%d,%d\n",<num1>, <num2>, <num3>, <num4>

```

These lines resemble ed subcommands to convert file1 into file2. The line numbers before the action letters shall pertain to file1; those after shall pertain to file2. Thus, by exchanging \(a\) for \(d\) and reading the line in reverse order, one can also determine how to convert file2 into file1. As in ed, identical pairs (where num \(1=\) num2) are abbreviated as a single number.
Following each of these lines, diff shall write to standard output all lines affected in the first file using the format:
" < \(\Delta \%\) s", <line>
and all lines affected in the second file using the format:
"> \({ }^{\circ} \mathrm{s}\) ", <line>
If there are lines affected in both file1 and file2 (as with the c subcommand), the changes are separated with a line consisting of three hyphens:
"---\n"

\section*{Diff -e Output Format}

With the -e option, a script shall be produced that shall, when provided as input to ed, along with an appended \(\mathbf{w}\) (write) command, convert file1 into file2. Only the a (append), \(\mathbf{c}\) (change), \(\mathbf{d}\) (delete), i (insert), and s (substitute) commands of ed shall be used in this script. Text lines, except those consisting of the single character period (' .'), shall be output as they appear in the file.

\section*{Diff -f Output Format}

With the -f option, an alternative format of script shall be produced. It is similar to that produced by \(-\mathbf{e}\), with the following differences:
1. It is expressed in reverse sequence; the output of -e orders changes from the end of the file to the beginning; the \(-\mathbf{f}\) from beginning to end.
2. The command form <lines> <command-letter> used by -e is reversed. For example, \(10 c\) with \(-\mathbf{e}\) would be \(c 10\) with \(-\mathbf{f}\).
3. The form used for ranges of line numbers is <space>-separated, rather than commaseparated.

\section*{Diff -c or -C Output Format}

With the -c or -C option, the output format shall consist of affected lines along with surrounding lines of context. The affected lines shall show which ones need to be deleted or changed in file1, and those added from file2. With the -c option, three lines of context, if available, shall be written before and after the affected lines. With the -C option, the user can specify how many lines of context are written. The exact format follows.
The name and last modification time of each file shall be output in the following format:
"*** \%s \%s\n", file1, <file1 timestamp>
"--- \%s \%s n ", file2, <file2 timestamp>
Each <file> field shall be the pathname of the corresponding file being compared. The pathname written for standard input is unspecified.

In the POSIX locale, each <timestamp> field shall be equivalent to the output from the following command:
date "+\%a \(\% b\) \%e \(\circ T\) \%Y"
without the trailing <newline>, executed at the time of last modification of the corresponding file (or the current time, if the file is standard input).
Then, the following output formats shall be applied for every set of changes.
First, a line shall be written in the following format:
"***************\n"
Next, the range of lines in file1 shall be written in the following format if the range contains two or more lines:
"*** \%d, \%d ****\n", <beginning line number>, <ending line number>
and the following format otherwise:
"*** \%d ****\n", <ending line number>
The ending line number of an empty range shall be the number of the preceding line, or 0 if the range is at the start of the file.
Next, the affected lines along with lines of context (unaffected lines) shall be written. Unaffected
lines shall be written in the following format:
" \(\Delta \Delta \%\) s", <unaffected_line>
Deleted lines shall be written as:
"- \(\Delta \%\) s", <deleted_line>
Changed lines shall be written as:
"! \(\Delta \%\) s", <changed_line>
Next, the range of lines in file2 shall be written in the following format if the range contains two or more lines:
"--- \%d, \%d ----\n", <beginning line number>, <ending line number>
and the following format otherwise:
"--- \%d ----\n", <ending line number>
Then, lines of context and changed lines shall be written as described in the previous formats. Lines added from file2 shall be written in the following format:
"+ \(\Delta \%\) s", <added_line>

\section*{Diff -u or -U Output Format}

The \(-\mathbf{u}\) or \(-\mathbf{U}\) options behave like the \(-\mathbf{c}\) or \(-\mathbf{C}\) options, except that the context lines are not repeated; instead, the context, deleted, and added lines are shown together, interleaved. The exact format follows.
The name and last modification time of each file shall be output in the following format:
"--- \(\Delta \% s \% s \% s \Delta \% s 0\), file1, <file1 timestamp>, <file1 frac>, <filel zone>
" \(+++\Delta \% s \% s \% s \Delta \% s 0\), file2, <file2 timestamp>, <file2 frac>, <file2 zone>
Each <file> field shall be the pathname of the corresponding file being compared, or the single character ' \(\quad\) ' if standard input is being compared. However, if the pathname contains a <tab> or a <newline>, or if it does not consist entirely of characters taken from the portable character set, the behavior is implementation-defined.
Each <timestamp> field shall be equivalent to the output from the following command:

without the trailing <newline>, executed at the time of last modification of the corresponding file (or the current time, if the file is standard input).
Each <frac> field shall be either empty, or a decimal point followed by at least one decimal digit, indicating the fractional-seconds part (if any) of the file timestamp. The number of fractional digits shall be at least the number needed to represent the file's timestamp without loss of information.

Each <zone> field shall be of the form "shhmm", where "shh" is a signed two-digit decimal number in the range -24 through +25 , and "mm" is an unsigned two-digit decimal number in the range 00 through 59. It represents the timezone of the timestamp as the number of hours (hh) and minutes \((\mathrm{mm})\) east \((+)\) or west \((-)\) of UTC for the timestamp. If the hours and minutes are both zero, the sign shall be ' + '. However, if the timezone is not an integral number of minutes away from UTC, the <zone> field is implementation-defined.
Then, the following output formats shall be applied for every set of changes.
First, the range of lines in each file shall be written in the following format:
"@@ \(\Delta-\% s \Delta+\% s \Delta @ @ ", ~<f i l e 1 ~ r a n g e>, ~<f i l e 2 ~ r a n g e>~\)

Each <range> field shall be of the form:
"\%1d", <beginning line number>
if the range contains exactly one line, and:
"\%1d, \%1d", <beginning line number>, <number of lines>
otherwise. If a range is empty, its beginning line number shall be the number of the line just before the range, or 0 if the empty range starts the file.

Next, the affected lines along with lines of context shall be written. Each non-empty unaffected line shall be written in the following format:
" \(\Delta \%\) s", <unaffected_line>
where the contents of the unaffected line shall be taken from file1. It is implementation-defined whether an empty unaffected line is written as an empty line or a line containing a single <space> character. This line also represents the same line of file2, even though file2's line may contain different contents due to the \(-\mathbf{b}\). Deleted lines shall be written as:
"-\%s", <deleted_line>
Added lines shall be written as:
"+\%s", <added_line>
The order of lines written shall be the same as that of the corresponding file. A deleted line shall never be written immediately after an added line.
If \(-\mathbf{U} n\) is specified, the output shall contain no more than \(n\) consecutive unaffected lines; and if the output contains an affected line and this line is adjacent to up to \(n\) consecutive unaffected lines in the corresponding file, the output shall contain these unaffected lines. -u shall act like -U3.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.
EXTENDED DESCRIPTION
None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 No differences were found.
1 Differences were found.
>1 An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

If lines at the end of a file are changed and other lines are added, diff output may show this as a delete and add, as a change, or as a change and add; diff is not expected to know which happened and users should not care about the difference in output as long as it clearly shows the differences between the files.

\section*{EXAMPLES}

If dir1 is a directory containing a directory named \(\mathbf{x}, \operatorname{dir} 2\) is a directory containing a directory named \(x, \operatorname{dir} 1 / x\) and \(\operatorname{dir} 2 / x\) both contain files named date.out, and \(\operatorname{dir} 2 / x\) contains a file named \(y\), the command:
```

diff -r dir1 dir2

```
could produce output similar to:
```

Common subdirectories: dir1/x and dir2/x
Only in dir2/x: y
diff -r dir1/x/date.out dir2/x/date.out
1c1
< Mon Jul 2 13:12:16 PDT 1990
---
> Tue Jun 19 21:41:39 PDT 1990

```

\section*{RATIONALE}

The -h option was omitted because it was insufficiently specified and does not add to applications portability.
Historical implementations employ algorithms that do not always produce a minimum list of differences; the current language about making every effort is the best this volume of IEEE Std 1003.1-200x can do, as there is no metric that could be employed to judge the quality of implementations against any and all file contents. The statement "This list should be minimal" clearly implies that implementations are not expected to provide the following output when comparing two 100-line files that differ in only one character on a single line:
```

1,100c1,100
all }100\mathrm{ lines from file1 preceded with "< "
---
all 100 lines from file2 preceded with "> "

```

The "Only \(\mathrm{in}^{\prime}\) " messages required when the -r option is specified are not used by most historical implementations if the -e option is also specified. It is required here because it provides useful information that must be provided to update a target directory hierarchy to match a source hierarchy. The "Common subdirectories" messages are written by System V and 4.3 BSD when the \(-\mathbf{r}\) option is specified. They are allowed here but are not required because they are reporting on something that is the same, not reporting a difference, and are not needed to update a target hierarchy.
The -c option, which writes output in a format using lines of context, has been included. The format is useful for a variety of reasons, among them being much improved readability and the ability to understand difference changes when the target file has line numbers that differ from another similar, but slightly different, copy. The patch utility is most valuable when working with difference listings using a context format. The BSD version of -c takes an optional argument specifying the amount of context. Rather than overloading -c and breaking the Utility Syntax Guidelines for diff, the standard developers decided to add a separate option for specifying a context diff with a specified amount of context (-C). Also, the format for context diffs was extended slightly in 4.3 BSD to allow multiple changes that are within context lines from each other to be merged together. The output format contains an additional four asterisks after the range of affected lines in the first filename. This was to provide a flag for old programs (like old versions of patch) that only understand the old context format. The version of context
described here does not require that multiple changes within context lines be merged, but it does not prohibit it either. The extension is upwards-compatible, so any vendors that wish to retain the old version of diff can do so by adding the extra four asterisks (that is, utilities that currently use diff and understand the new merged format will also understand the old unmerged format, but not vice versa).

The \(-\mathbf{u}\) and \(-\mathbf{U}\) options of GNU diff have been included. Their output format, designed by Wayne Davison, takes up less space than -c and -C format, and in many cases is easier to read. The format's timestamps do not vary by locale, so LC_TIME does not affect it. The format's line numbers are rendered with the \(\% 1 \mathrm{~d}\) format, not \(\% d\), because the file format notation rules would allow extra <blank>s to appear around the numbers.

The substitute command was added as an additional format for the \(-\mathbf{e}\) option. This was added to provide implementations with a way to fix the classic "dot alone on a line" bug present in many versions of diff. Since many implementations have fixed this bug, the standard developers decided not to standardize broken behavior, but rather to provide the necessary tool for fixing the bug. One way to fix this bug is to output two periods whenever a lone period is needed, then terminate the append command with a period, and then use the substitute command to convert the two periods into one period.

The BSD-derived -r option was added to provide a mechanism for using diff to compare two file system trees. This behavior is useful, is standard practice on all BSD-derived systems, and is not easily reproducible with the find utility.
The requirement that diff not compare files in some circumstances, even though they have the same name, is based on the actual output of historical implementations. The specified behavior precludes the problems arising from running into FIFOs and other files that would cause diff to hang waiting for input with no indication to the user that diff was hung. A previous version of this standard specified the output format more precisely, but in practice this requirement was widely ignored and the benefit of standardization seemed small, so it is now unspecified. In most common usage, diff -r should indicate differences in the file hierarchies, not the difference of contents of devices pointed to by the hierarchies.

Many early implementations of diff require seekable files. Since the System Interfaces volume of IEEE Std 1003.1-200x supports named pipes, the standard developers decided that such a restriction was unreasonable. Note also that the allowed filename - almost always refers to a pipe.
No directory search order is specified for diff. The historical ordering is, in fact, not optimal, in that it prints out all of the differences at the current level, including the statements about all common subdirectories before recursing into those subdirectories.
The message:
"diff \%s \%s \%s\n", <diff_options>, <filename1>, <filename2>
does not vary by locale because it is the representation of a command, not an English sentence.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO
cmp, comm, ed, find

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{Issue 5}

The FUTURE DIRECTIONS section is added.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The -f option is added.

The output format for \(-\mathbf{c}\) or \(-\mathbf{C}\) format is changed to align with changes to the IEEE P1003.2b draft standard resulting from IEEE PASC Interpretation 1003.2 \#71.

The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/20 is applied, changing the STDOUT section. This changes the specification of diff -c so that it agrees with existing practice when contexts contain zero lines or one line.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-103 and SD5-XCU-ERN-120 are applied, adding the \(-\mathbf{u}\) option.
Austin Group Interpretation 1003.1-2001 \#115 and \#114 are applied.

NAME
dirname - return the directory portion of a pathname

\section*{SYNOPSIS}
```

dirname string

```

\section*{DESCRIPTION}

The string operand shall be treated as a pathname, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.266, Pathname. The string string shall be converted to the name of the directory containing the filename corresponding to the last pathname component in string, performing actions equivalent to the following steps in order:
1. If string is I/, skip steps 2 to 5 .
2. If string consists entirely of slash characters, string shall be set to a single slash character. In this case, skip steps 3 to 8 .
3. If there are any trailing slash characters in string, they shall be removed.
4. If there are no slash characters remaining in string, string shall be set to a single period character. In this case, skip steps 5 to 8.
5. If there are any trailing non-slash characters in string, they shall be removed.
6. If the remaining string is \(/ /\), it is implementation-defined whether steps 7 and 8 are skipped or processed.
7. If there are any trailing slash characters in string, they shall be removed.
8. If the remaining string is empty, string shall be set to a single slash character.

The resulting string shall be written to standard output.

\section*{OPTIONS}

None.
OPERANDS
The following operand shall be supported:
string A string.
STDIN
Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of dirname:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

The dirname utility shall write a line to the standard output in the following format:
"\%s\n", <resulting string>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

The definition of pathname specifies implementation-defined behavior for pathnames starting with two slash characters. Therefore, applications shall not arbitrarily add slashes to the beginning of a pathname unless they can ensure that there are more or less than two or are prepared to deal with the implementation-defined consequences.

\section*{EXAMPLES}
\begin{tabular}{|l|l|}
\hline \multicolumn{1}{|c|}{ Command } & \multicolumn{1}{c|}{ Results } \\
\hline dirname \(/\) & \(/\) \\
dirname \(/ /\) & \(/\) or \(/ /\) \\
dirname \(/ a / b /\) & \(/ a\) \\
dirname \(/ / a / / b / /\) & \(/ / a\) \\
dirname & Unspecified \\
dirname \(a\) &.\((\$ ?=0)\) \\
dirname \("\) " &.\((\$ ?=0)\) \\
dirname \(/ a\) & \(/\) \\
dirname \(/ a / b\) & \(/ a\) \\
dirname \(a / b\) & \(a\) \\
\hline
\end{tabular}

\section*{RATIONALE}

The dirname utility originated in System III. It has evolved through the System V releases to a version that matches the requirements specified in this description in System V Release 3. 4.3 BSD and earlier versions did not include dirname.

The behaviors of basename and dirname in this volume of IEEE Std 1003.1-200x have been coordinated so that when string is a valid pathname:
```

\$(basename "string")

```
would be a valid filename for the file in the directory:
```

\$(dirname "string")

```

This would not work for the versions of these utilities in early proposals due to the way processing of trailing slashes was specified. Consideration was given to leaving processing unspecified if there were trailing slashes, but this cannot be done; the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.266, Pathname allows trailing slashes. The basename and dirname utilities have to specify consistent handling for all valid pathnames.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
basename, Section 2.5

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{NAME}
du - estimate file space usage

\section*{SYNOPSIS}
du [-a|-s] [-kx] [-H|-L] [file...]

\section*{DESCRIPTION}

By default, the \(d u\) utility shall write to standard output the size of the file space allocated to, and the size of the file space allocated to each subdirectory of, the file hierarchy rooted in each of the specified files. By default, when a symbolic link is encountered on the command line or in the file hierarchy, \(d u\) shall count the size of the symbolic link (rather than the file referenced by the link), and shall not follow the link to another portion of the file hierarchy. The size of the file space allocated to a file of type directory shall be defined as the sum total of space allocated to all files in the file hierarchy rooted in the directory plus the space allocated to the directory itself.
When \(d u\) cannot stat () files or stat() or read directories, it shall report an error condition and the final exit status is affected. Files with multiple links shall be counted and written for only one entry. The directory entry that is selected in the report is unspecified. By default, file sizes shall be written in 512-byte units, rounded up to the next 512-byte unit.

\section*{OPTIONS}

The \(d u\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a In addition to the default output, report the size of each file not of type directory in the file hierarchy rooted in the specified file. Regardless of the presence of the -a option, non-directories given as file operands shall always be listed.
-H If a symbolic link is specified on the command line, \(d u\) shall count the size of the file or file hierarchy referenced by the link.
\(-\mathbf{k}\) Write the files sizes in units of 1024 bytes, rather than the default 512-byte units.
-L If a symbolic link is specified on the command line or encountered during the traversal of a file hierarchy, \(d u\) shall count the size of the file or file hierarchy referenced by the link.
-s Instead of the default output, report only the total sum for each of the specified files.
-x When evaluating file sizes, evaluate only those files that have the same device as the file specified by the file operand.
Specifying more than one of the mutually-exclusive options -H and \(-\mathbf{L}\) shall not be considered an error. The last option specified shall determine the behavior of the utility.

OPERANDS
The following operand shall be supported:
file The pathname of a file whose size is to be written. If no file is specified, the current directory shall be used.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(d u\) :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The output from \(d u\) shall consist of the amount of space allocated to a file and the name of the file, in the following format:
"\%d \%s\n", <size>, <pathname>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

None.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The use of 512-byte units is historical practice and maintains compatibility with \(l s\) and other utilities in this volume of IEEE Std 1003.1-200x. This does not mandate that the file system itself be based on 512-byte blocks. The \(-\mathbf{k}\) option was added as a compromise measure. It was agreed by the standard developers that 512 bytes was the best default unit because of its complete historical consistency on System V (versus the mixed 512/1024-byte usage on BSD systems), and
that a \(-\mathbf{k}\) option to switch to 1024 -byte units was a good compromise. Users who prefer the 1024 -byte quantity can easily alias \(d u\) to \(d u-\mathbf{k}\) without breaking the many historical scripts relying on the 512-byte units.
The -b option was added to an early proposal to provide a resolution to the situation where System V and BSD systems give figures for file sizes in blocks, which is an implementationdefined concept. (In common usage, the block size is 512 bytes for System V and 1024 bytes for BSD systems.) However, -b was later deleted, since the default was eventually decided as 512-byte units.

Historical file systems provided no way to obtain exact figures for the space allocation given to files. There are two known areas of inaccuracies in historical file systems: cases of indirect blocks being used by the file system or sparse files yielding incorrectly high values. An indirect block is space used by the file system in the storage of the file, but that need not be counted in the space allocated to the file. A sparse file is one in which an \(l \operatorname{seek}()\) call has been made to a position beyond the end of the file and data has subsequently been written at that point. A file system need not allocate all the intervening zero-filled blocks to such a file. It is up to the implementation to define exactly how accurate its methods are.
The -a and -s options were mutually-exclusive in the original version of \(d u\). The POSIX Shell and Utilities description is implied by the language in the SVID where -s is described as causing "only the grand total" to be reported. Some systems may produce output for -sa, but a Strictly Conforming POSIX Shell and Utilities Application cannot use that combination.
The -a and -s options were adopted from the SVID except that the System V behavior of not listing non-directories explicitly given as operands, unless the -a option is specified, was considered a bug; the BSD-based behavior (report for all operands) is mandated. The default behavior of \(d u\) in the SVID with regard to reporting the failure to read files (it produces no messages) was considered counter-intuitive, and thus it was specified that the POSIX Shell and Utilities default behavior shall be to produce such messages. These messages can be turned off with shell redirection to achieve the System \(V\) behavior.
The -x option is historical practice on recent BSD systems. It has been adopted by this volume of IEEE Std 1003.1-200x because there was no other historical method of limiting the \(d u\) search to a single file hierarchy. This limitation of the sear

Issue 7
The \(d u\) utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
echo - write arguments to standard output

\section*{SYNOPSIS}
```

echo [string...]

```

\section*{DESCRIPTION}

The echo utility writes its arguments to standard output, followed by a <newline>. If there are no arguments, only the <newline> is written.

\section*{OPTIONS}

The echo utility shall not recognize the "--" argument in the manner specified by Guideline 10 of the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines; "--" shall be recognized as a string operand.
Implementations shall not support any options.
OPERANDS
The following operands shall be supported:
string \(\quad\) A string to be written to standard output. If the first operand is \(\mathbf{- n}\), or if any of the operands contain a backslash \(\left({ }^{\prime} \backslash^{\prime}\right)\) character, the results are implementationdefined.

On XSI-conformant systems, if the first operand is \(-\mathbf{n}\), it shall be treated as a string, not an option. The following character sequences shall be recognized on XSIconformant systems within any of the arguments:
\a Write an <alert>.
\b Write a <backspace>.
Ic Suppress the <newline> that otherwise follows the final argument in the output. All characters following the ' \(\backslash c\) ' in the arguments shall be ignored.

Write a <form-feed>.
Write a <newline>.
Write a <carriage-return>.
Write a <tab>.
Write a <vertical-tab>.
Write a backslash character.
\(\backslash\) num Write an 8-bit value that is the zero, one, two, or three-digit octal number num.

\section*{STDIN}

Not used.
INPUT FILES
None.

\section*{ENVIRONMENT VARIABLES}
\begin{tabular}{|c|c|c|}
\hline & LANG & Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.) \\
\hline & LC_ALL & If set to a non-empty string value, override the values of all the other internationalization variables. \\
\hline \multirow[t]{2}{*}{xSI} & LC_CTYPE & Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments). \\
\hline & LC_MESSA & \begin{tabular}{l}
ES \\
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
\end{tabular} \\
\hline XSI & NLSPATH & Determine the location of message catalogs for the processing of LC_MESSAGES. \\
\hline
\end{tabular}

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

The echo utility arguments shall be separated by single <space>s and a <newline> shall follow xsi the last argument. Output transformations shall occur based on the escape sequences in the input. See the OPERANDS section.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

It is not possible to use echo portably across all POSIX systems unless both -n (as the first argument) and escape sequences are omitted.
The printf utility can be used portably to emulate any of the traditional behaviors of the echo utility as follows (assuming that IFS has its standard value or is unset):
- The historic System V echo and the requirements on XSI implementations in this volume of IEEE Std 1003.1-200x are equivalent to:
```

printf "%b\n" "\$*"

```
- The BSD echo is equivalent to:
```

if [ "X\$1" = "X-n" ]
then

```
```

            shift
            printf "%s" "$*"
    else
printf "%s\n" "\$*"
fi

```

New applications are encouraged to use printf instead of echo.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The echo utility has not been made obsolescent because of its extremely widespread use in historical applications. Conforming applications that wish to do prompting without <newline>s or that could possibly be expecting to echo a \(-\mathbf{n}\), should use the printf utility derived from the Ninth Edition system.
As specified, echo writes its arguments in the simplest of ways. The two different historical versions of echo vary in fatally incompatible ways.
The BSD echo checks the first argument for the string - \(\mathbf{n}\) which causes it to suppress the <newline> that would otherwise follow the final argument in the output.

The System V echo does not support any options, but allows escape sequences within its operands, as described for XSI implementations in the OPERANDS section.

The echo utility does not support Utility Syntax Guideline 10 because historical applications depend on echo to echo all of its arguments, except for the -n option in the BSD version.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO
printf

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
In the OPTIONS section, the last sentence is changed to indicate that implementations "do not" support any options; in the previous issue this said "need not".
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- A set of character sequences is defined as string operands.
- LC_CTYPE is added to the list of environment variables affecting echo.
- In the OPTIONS section, implementations shall not support any options.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/21 is applied, so that the echo utility can accommodate historical BSD behavior.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
ed - edit text

\section*{SYNOPSIS}
\[
\text { ed }[-\mathrm{p} \text { string] [-s] [file] }
\]

\section*{DESCRIPTION}

The ed utility is a line-oriented text editor that uses two modes: command mode and input mode. In command mode the input characters shall be interpreted as commands, and in input mode they shall be interpreted as text. See the EXTENDED DESCRIPTION section.
If an operand is ' - ', the results are unspecified.

\section*{OPTIONS}

The ed utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for the unspecified usage of \({ }^{\prime}-\quad\).
The following options shall be supported:
-p string Use string as the prompt string when in command mode. By default, there shall be no prompt string.
-s Suppress the writing of byte counts by \(\mathbf{e}, \mathbf{E}, \mathbf{r}\), and \(\mathbf{w}\) commands and of the '!' prompt after a !command.

OPERANDS
The following operand shall be supported:
file If the file argument is given, ed shall simulate an e command on the file named by the pathname, file, before accepting commands from the standard input.

\section*{STDIN}

The standard input shall be a text file consisting of commands, as described in the EXTENDED DESCRIPTION section.

\section*{INPUT FILES}

The input files shall be text files.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of ed:
HOME Determine the pathname of the user's home directory.
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.
\begin{tabular}{|c|c|c|c|}

\hline
\end{tabular}
the \(\mathbf{s}\) substitute command) to specify portions of a line to be substituted.

\section*{Addresses in ed}

Addressing in ed relates to the current line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. If the edit buffer is not empty, the initial value for the current line shall be the last line in the edit buffer; otherwise, zero.

Addresses shall be constructed as follows:
1. The period character ( \({ }^{\prime} . \prime\) ) shall address the current line.
2. The dollar sign character ( \({ }^{\prime} \$^{\prime}\) ) shall address the last line of the edit buffer.
3. The positive decimal number \(n\) shall address the \(n\)th line of the edit buffer.
4. The apostrophe-x character pair ("'x") shall address the line marked with the mark name character \(x\), which shall be a lowercase letter from the portable character set. It shall be an error if the character has not been set to mark a line or if the line that was marked is not currently present in the edit buffer.
5. A BRE enclosed by slash characters ('/') shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of slash characters shall address the next line for which the line excluding the terminating <newline> matches the last BRE encountered. In addition, the second slash can be omitted at the end of a command line. Within the BRE, a backslash-slash pair (" \(\backslash /\) ") shall represent a literal slash instead of the BRE delimiter. If necessary, the search shall wrap around to the beginning of the buffer and continue up to and including the current line, so that the entire buffer is searched.
6. A BRE enclosed by question-mark characters ( \(r^{\prime}\) ? ) shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the BRE. The BRE consisting of a null BRE delimited by a pair of question-mark characters ("??") shall address the previous line for which the line excluding the terminating <newline> matches the last BRE encountered. In addition, the second question-mark can be omitted at the end of a command line. Within the BRE, a backslash-question-mark pair ("\\)?") shall represent a literal question mark instead of the BRE delimiter. If necessary, the search shall wrap around to the end of the buffer and continue up to and including the current line, so that the entire buffer is searched.
7. A plus-sign \(\left(\prime^{\prime \prime}\right)\) or hyphen character \(\left(\prime^{\prime}\right)\) followed by a decimal number shall address the current line plus or minus the number. A plus-sign or hyphen character not followed by a decimal number shall address the current line plus or minus 1.
Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:
- A plus-sign or hyphen character followed by a decimal number shall add or subtract, respectively, the indicated number of lines to or from the address. A plus-sign or hyphen character not followed by a decimal number shall add or subtract 1 to or from the address.
- A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer. It shall be an error if a search for a BRE fails to find a matching line.

Commands accept zero, one, or two addresses. If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain, for the specified command.
Addresses shall be separated from each other by a comma (' , ') or semicolon character ( \({ }^{\prime} ;^{\prime}\) ). In the case of a semicolon separator, the current line ( \({ }^{\prime} .{ }^{\prime}\) ) shall be set to the first address, and only then will the second address be calculated. This feature can be used to determine the starting line for forwards and backwards searches; see rules 5 . and 6.

Addresses can be omitted on either side of the comma or semicolon separator, in which case the resulting address pairs shall be as follows:
\begin{tabular}{|l|l|}
\hline Specified & \multicolumn{1}{|c|}{ Resulting } \\
\hline , & 1 , \$ \\
, addr & 1 , addr \\
addr , & addr , addr \\
; & ; \$ \\
; addr & . i addr \\
addr ; & addr ; addr \\
\hline
\end{tabular}

Any <blank>s included between addresses, address separators, or address offsets shall be ignored.

\section*{Commands in ed}

In the following list of ed commands, the default addresses are shown in parentheses. The number of addresses shown in the default shall be the number expected by the command. The parentheses are not part of the address; they show that the given addresses are the default.

It is generally invalid for more than one command to appear on a line. However, any command (except \(\mathbf{e}, \mathbf{E}, \mathbf{f}, \mathbf{q}, \mathbf{Q}, \mathbf{r}, \mathbf{w}\), and !) can be suffixed by the letter \(\mathbf{l}, \mathbf{n}\), or \(\mathbf{p}\); in which case, except for the \(\mathbf{l}, \mathbf{n}\), and \(\mathbf{p}\) commands, the command shall be executed and then the new current line shall be written as described below under the \(\mathbf{l}, \mathbf{n}\), and \(\mathbf{p}\) commands. When an \(\mathbf{l}, \mathbf{n}\), or \(\mathbf{p}\) suffix is used with an \(1, \mathbf{n}\), or \(\mathbf{p}\) command, the command shall write to standard output as described below, but it is unspecified whether the suffix writes the current line again in the requested format or whether the suffix has no effect. For example, the \(\mathbf{p l}\) command (base \(\mathbf{p}\) command with an 1 suffix) shall either write just the current line or write it twice-once as specified for \(\mathbf{p}\) and once as specified for \(\mathbf{1}\). Also, the \(\mathbf{g}, \mathbf{G}, \mathbf{v}\), and \(\mathbf{V}\) commands shall take a command as a parameter.
Each address component can be preceded by zero or more <blank>s. The command letter can be preceded by zero or more <blank>s. If a suffix letter ( \(\mathbf{l}, \mathbf{n}\), or \(\mathbf{p}\) ) is given, the application shall ensure that it immediately follows the command.

The \(\mathbf{e}, \mathbf{E}, \mathbf{f}, \mathbf{r}\), and \(\mathbf{w}\) commands shall take an optional file parameter, separated from the command letter by one or more <blank>s.
If changes have been made in the buffer since the last \(\mathbf{w}\) command that wrote the entire buffer, \(e d\) shall warn the user if an attempt is made to destroy the editor buffer via the \(\mathbf{e}\) or \(\mathbf{q}\) commands. The ed utility shall write the string:
"? \({ }^{n}\) n"
(followed by an explanatory message if help mode has been enabled via the \(\mathbf{H}\) command) to standard output and shall continue in command mode with the current line number unchanged. If the \(\mathbf{e}\) or \(\mathbf{q}\) command is repeated with no intervening command, it shall take effect.
If a terminal disconnect (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, Modem Disconnect and Closing a Device Terminal), is detected:
- If accompanied by a SIGHUP signal, the ed utility shall operate as described in the ASYNCHRONOUS EVENTS section for a SIGHUP signal.
- If not accompanied by a SIGHUP signal, the ed utility shall act as if an end-of-file had been detected on standard input.

If an end-of-file is detected on standard input:
- If the ed utility is in input mode, ed shall terminate input mode and return to command mode. It is unspecified if any partially entered lines (that is, input text without a terminating <newline>) are discarded from the input text.
- If the ed utility is in command mode, it shall act as if a \(\mathbf{q}\) command had been entered.

If the closing delimiter of an RE or of a replacement string (for example, ' \(/{ }^{\prime}\) ) in a \(\mathbf{g}, \mathbf{G}, \mathbf{s}, \mathbf{v}\), or \(\mathbf{V}\) command would be the last character before a <newline>, that delimiter can be omitted, in which case the addressed line shall be written. For example, the following pairs of commands are equivalent:
```

s/s1/s2 s/s1/s2/p
g/s1 g/s1/p
?s1 ?s1?

```

If an invalid command is entered, \(e d\) shall write the string:
"? \({ }^{n}\) "
(followed by an explanatory message if help mode has been enabled via the \(\mathbf{H}\) command) to standard output and shall continue in command mode with the current line number unchanged.

\section*{Append Command}

Synopsis:
\[
\begin{aligned}
& \text { (.) a } \\
& \text { <text> }
\end{aligned}
\]

The a command shall read the given text and append it after the addressed line; the current line number shall become the address of the last inserted line or, if there were none, the addressed line. Address 0 shall be valid for this command; it shall cause the appended text to be placed at the beginning of the buffer.

Change Command
Synopsis:

The c command shall delete the addressed lines, then accept input text that replaces these lines; the current line shall be set to the address of the last line input; or, if there were none, at the line after the last line deleted; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

\section*{Delete Command}

Synopsis: (.,.)d
The d command shall delete the addressed lines from the buffer. The address of the line after the last line deleted shall become the current line number; if the lines deleted were originally at the end of the buffer, the current line number shall be set to the address of the new last line; if no lines remain in the buffer, the current line number shall be set to zero.

\section*{Edit Command}

Synopsis: e [file]
The e command shall delete the entire contents of the buffer and then read in the file named by the pathname file. The current line number shall be set to the address of the last line of the buffer. If no pathname is given, the currently remembered pathname, if any, shall be used (see the \(\mathbf{f}\) command). The number of bytes read shall be written to standard output, unless the -s option was specified, in the following format:
"\%d\n", <number of bytes read>
The name file shall be remembered for possible use as a default pathname in subsequent \(\mathbf{e}, \mathbf{E}, \mathbf{r}\), and \(\mathbf{w}\) commands. If file is replaced by ' '', the rest of the line shall be taken to be a shell command line whose output is to be read. Such a shell command line shall not be remembered as the current file. All marks shall be discarded upon the completion of a successful e command. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

Edit Without Checking Command
Synopsis: E [file]
The \(\mathbf{E}\) command shall possess all properties and restrictions of the \(\mathbf{e}\) command except that the editor shall not check to see whether any changes have been made to the buffer since the last \(\mathbf{w}\) command.

\section*{Filename Command}

Synopsis: f [file]
If file is given, the f command shall change the currently remembered pathname to file; whether the name is changed or not, it shall then write the (possibly new) currently remembered pathname to the standard output in the following format:
"\%s\n", <pathname>
The current line number shall be unchanged.

\section*{Global Command}

Synopsis: \(\quad(1, \$) \mathrm{g} / R E /\) command list
In the \(\mathbf{g}\) command, the first step shall be to mark every line for which the line excluding the terminating <newline> matches the given RE. Then, going sequentially from the beginning of the file to the end of the file, the given command list shall be executed for each marked line, with the current line number set to the address of that line. Any line modified by the command list shall be unmarked. When the \(\mathbf{g}\) command completes, the current line number shall have the value assigned by the last command in the command list. If there were no matching lines, the current line number shall not be changed. A single command or the first of a list of commands shall appear on the same line as the global command. All lines of a multi-line list except the last line shall be ended with a backslash preceding the terminating <newline>; the \(\mathbf{a}, \mathbf{i}\), and \(\mathbf{c}\)
commands and associated input are permitted. The ' .' terminating input mode can be omitted if it would be the last line of the command list. An empty command list shall be equivalent to the \(\mathbf{p}\) command. The use of the \(\mathbf{g}, \mathbf{G}, \mathbf{v}, \mathbf{V}\), and! commands in the command list produces undefined results. Any character other than <space> or <newline> can be used instead of a slash to delimit the RE. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.

\section*{Interactive Global Command}

Synopsis: \(\quad(1, \$) G / R E /\)
In the G command, the first step shall be to mark every line for which the line excluding the terminating <newline> matches the given RE. Then, for every such line, that line shall be written, the current line number shall be set to the address of that line, and any one command (other than one of the \(\mathbf{a}, \mathbf{c}, \mathbf{i}, \mathbf{g}, \mathbf{G}, \mathbf{v}\), and \(\mathbf{V}\) commands) shall be read and executed. A <newline> shall act as a null command (causing no action to be taken on the current line); an ' \&' shall cause the re-execution of the most recent non-null command executed within the current invocation of \(G\). Note that the commands input as part of the execution of the \(\mathbf{G}\) command can address and affect any lines in the buffer. Any line modified by the command shall be unmarked. The final value of the current line number shall be the value set by the last command successfully executed. (Note that the last command successfully executed shall be the G command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number shall not be changed. The G command can be terminated by a SIGINT signal. Any character other than <space> or <newline> can be used instead of a slash to delimit the RE and the replacement. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash.

\section*{Help Command}

Synopsis:

The \(\mathbf{h}\) command shall write a short message to standard output that explains the reason for the most recent '?' notification. The current line number shall be unchanged.

The \(\mathbf{H}\) command shall cause ed to enter a mode in which help messages (see the \(\mathbf{h}\) command) shall be written to standard output for all subsequent '?' notifications. The H command alternately shall turn this mode on and off; it is initially off. If the help-mode is being turned on, the \(\mathbf{H}\) command also explains the previous ' ?' notification, if there was one. The current line number shall be unchanged.

\section*{Insert Command}

Synopsis: (.) i
<text>

The \(\mathbf{i}\) command shall insert the given text before the addressed line; the current line is set to the last inserted line or, if there was none, to the addressed line. This command differs from the a command only in the placement of the input text. Address 0 shall be valid for this command; it shall be interpreted as if address 1 were specified.

\section*{Join Command}

Synopsis: (.,.+1) j
The \(\mathbf{j}\) command shall join contiguous lines by removing the appropriate <newline>s. If exactly one address is given, this command shall do nothing. If lines are joined, the current line number shall be set to the address of the joined line; otherwise, the current line number shall be unchanged.

\section*{Mark Command}

Synopsis: (.) kx
The \(\mathbf{k}\) command shall mark the addressed line with name \(x\), which the application shall ensure is a lowercase letter from the portable character set. The address "'x" shall then refer to this line; the current line number shall be unchanged.

\section*{List Command}

Synopsis: (.,.) 1
The 1 command shall write to standard output the addressed lines in a visually unambiguous form. The characters listed in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1,
 be written as the corresponding escape sequence; the ' \(\backslash n\) ' in that table is not applicable. Nonprintable characters not in the table shall be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first).
Long lines shall be folded, with the point of folding indicated by <newline> preceded by a backslash; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a ' \(\$\) ', and ' \(\$\) ' characters within the text shall be written with a preceding backslash. An 1 command can be appended to any other command other than \(\mathbf{e}, \mathbf{E}, \mathbf{f}, \mathbf{q}, \mathbf{Q}, \mathbf{r}, \mathbf{w}\), or !. The current line number shall be set to the address of the last line written.

\section*{Move Command}

Synopsis: (...)maddress
The \(\mathbf{m}\) command shall reposition the addressed lines after the line addressed by address. Address 0 shall be valid for address and cause the addressed lines to be moved to the beginning of the buffer. It shall be an error if address address falls within the range of moved lines. The current line number shall be set to the address of the last line moved.
Number Command
Synopsis: \(\quad(.,)\).

The \(\mathbf{n}\) command shall write to standard output the addressed lines, preceding each line by its line number and \(a<t a b>\); the current line number shall be set to the address of the last line written. The \(\mathbf{n}\) command can be appended to any command other than \(\mathbf{e}, \mathbf{E}, \mathbf{f}, \mathbf{q}, \mathbf{Q}, \mathbf{r}, \mathbf{w}\), or !.

\section*{Print Command}

Synopsis: (.,.) p
The \(\mathbf{p}\) command shall write to standard output the addressed lines; the current line number shall be set to the address of the last line written. The \(\mathbf{p}\) command can be appended to any command other than \(\mathbf{e}, \mathbf{E}, \mathbf{f}, \mathbf{q}, \mathbf{Q}, \mathbf{r}, \mathbf{w}\), or !.

Prompt Command
Synopsis: \(\quad \mathrm{P}\)
The \(\mathbf{P}\) command shall cause \(e d\) to prompt with an asterisk ( \({ }^{\prime}{ }^{\prime \prime}\) ) (or string, if \(-\mathbf{p}\) is specified) for all subsequent commands. The \(\mathbf{P}\) command alternatively shall turn this mode on and off; it shall be initially on if the -p option is specified; otherwise, off. The current line number shall be unchanged.

Quit Command
Synopsis: q
The \(\mathbf{q}\) command shall cause \(e d\) to exit. If the buffer has changed since the last time the entire buffer was written, the user shall be warned, as described previously.

\section*{Quit Without Checking Command}

Synopsis: Q
The \(\mathbf{Q}\) command shall cause ed to exit without checking whether changes have been made in the buffer since the last \(\mathbf{w}\) command.

\section*{Read Command \\ Synopsis: (\$)r [file]}

The \(\mathbf{r}\) command shall read in the file named by the pathname file and append it after the addressed line. If no file argument is given, the currently remembered pathname, if any, shall be used (see the e and fcommands). The currently remembered pathname shall not be changed unless there is no remembered pathname. Address 0 shall be valid for \(\mathbf{r}\) and shall cause the file to be read at the beginning of the buffer. If the read is successful, and \(-\mathbf{s}\) was not specified, the number of bytes read shall be written to standard output in the following format:
"\%d\n", <number of bytes read>
The current line number shall be set to the address of the last line read in. If file is replaced by ' \(!\) ', the rest of the line shall be taken to be a shell command line whose output is to be read. Such a shell command line shall not be remembered as the current pathname.

\section*{Substitute Command}

Synopsis: (.,.)s/RE/replacement/flags
The s command shall search each addressed line for an occurrence of the specified RE and replace either the first or all (non-overlapped) matched strings with the replacement; see the following description of the \(\mathbf{g}\) suffix. It is an error if the substitution fails on every addressed line. Any character other than <space> or <newline> can be used instead of a slash to delimit the RE and the replacement. Within the RE, the RE delimiter itself can be used as a literal character if it is preceded by a backslash. The current line shall be set to the address of the last line on which a substitution occurred.
An ampersand ( \(\prime^{\prime} \delta^{\prime}\) ) appearing in the replacement shall be replaced by the string matching the RE on the current line. The special meaning of ' \({ }_{\delta}\) ' in this context can be suppressed by

\begin{abstract}
preceding it by backslash. As a more general feature, the characters ' \(\backslash \mathrm{n}^{\prime}\), where \(n\) is a digit, shall be replaced by the text matched by the corresponding back-reference expression. If the corresponding back-reference expression does not match, then the characters ' \(\backslash \mathrm{n}\) ' shall be replaced by the empty string. When the character \({ }^{\prime} \%^{\prime}\) is the only character in the replacement, the replacement used in the most recent substitute command shall be used as the replacement in the current substitute command; if there was no previous substitute command, the use of \({ }^{\prime} \%\) ' in this manner shall be an error. The ' \(\%\) ' shall lose its special meaning when it is in a replacement string of more than one character or is preceded by a backslash. For each backslash (' \(\backslash^{\prime}\) ) encountered in scanning replacement from beginning to end, the following character shall lose its special meaning (if any). It is unspecified what special meaning is given to any character other than ' \(\&\) ', \(\backslash\) ', ' \(\%\) ', or digits.

A line can be split by substituting a <newline> into it. The application shall ensure it escapes the <newline> in the replacement by preceding it by backslash. Such substitution cannot be done as part of a \(\mathbf{g}\) or \(\mathbf{v}\) command list. The current line number shall be set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number shall be unchanged. If a line is split, a substitution shall be considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces.

The application shall ensure that the value of flags is zero or more of:
count Substitute for the countth occurrence only of the RE found on each addressed line.
g Globally substitute for all non-overlapping instances of the RE rather than just the first one. If both \(\mathbf{g}\) and count are specified, the results are unspecified.
1 Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the 1 command.
n Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the \(\mathbf{n}\) command.
p Write to standard output the final line in which a substitution was made. The line shall be written in the format specified for the \(\mathbf{p}\) command.

Copy Command
Synopsis: (.r.)taddress
The \(\mathbf{t}\) command shall be equivalent to the \(\mathbf{m}\) command, except that a copy of the addressed lines shall be placed after address address (which can be 0); the current line number shall be set to the address of the last line added.

\section*{Undo Command}

Synopsis: u
The \(\mathbf{u}\) command shall nullify the effect of the most recent command that modified anything in the buffer, namely the most recent \(\mathbf{a}, \mathbf{c}, \mathbf{d}, \mathbf{g}, \mathbf{i}, \mathbf{j}, \mathbf{m}, \mathbf{r}, \mathbf{s}, \mathbf{t}, \mathbf{u}, \mathbf{v}, \mathbf{G}\), or \(\mathbf{V}\) command. All changes made to the buffer by a \(\mathbf{g}, \mathbf{G}, \mathbf{v}\), or \(\mathbf{V}\) global command shall be undone as a single change; if no changes were made by the global command (such as with \(\mathbf{g} / \mathrm{RE} / \mathbf{p}\) ), the \(\mathbf{u}\) command shall have no effect. The current line number shall be set to the value it had immediately before the command being undone started.
\end{abstract}

\section*{Global Non-Matched Command}

Synopsis: \((1, \$) v / R E /\) command list
This command shall be equivalent to the global command \(\mathbf{g}\) except that the lines that are marked during the first step shall be those for which the line excluding the terminating <newline> does not match the RE.

\section*{Interactive Global Not-Matched Command}

Synopsis: (1, \$) V/RE/
This command shall be equivalent to the interactive global command \(\mathbf{G}\) except that the lines that are marked during the first step shall be those for which the line excluding the terminating <newline> does not match the RE.

\section*{Write Command}

Synopsis: \((1, \$) w\) [file]
The \(\mathbf{w}\) command shall write the addressed lines into the file named by the pathname file. The command shall create the file, if it does not exist, or shall replace the contents of the existing file. The currently remembered pathname shall not be changed unless there is no remembered pathname. If no pathname is given, the currently remembered pathname, if any, shall be used (see the \(\mathbf{e}\) and \(\mathbf{f}\) commands); the current line number shall be unchanged. If the command is successful, the number of bytes written shall be written to standard output, unless the -s option was specified, in the following format:
"\%d\n", <number of bytes written>
If file begins with '!', the rest of the line shall be taken to be a shell command line whose standard input shall be the addressed lines. Such a shell command line shall not be remembered as the current pathname. This usage of the write command with '!' shall not be considered as a "last w command that wrote the entire buffer", as described previously; thus, this alone shall not prevent the warning to the user if an attempt is made to destroy the editor buffer via the \(\mathbf{e}\) or q commands.

\section*{Line Number Command \\ Synopsis: \(\quad(\$)=\)}

The line number of the addressed line shall be written to standard output in the following format:
"\%d\n", <line number>
The current line number shall be unchanged by this command.

\section*{Shell Escape Command}
```

Synopsis: !command

```

The remainder of the line after the '!' shall be sent to the command interpreter to be interpreted as a shell command line. Within the text of that shell command line, the unescaped character ' \(\%\) ' shall be replaced with the remembered pathname; if a '!' appears as the first character of the command, it shall be replaced with the text of the previous shell command executed via' !'. Thus, " ! ! " shall repeat the previous !command. If any replacements of ' \(\%\) ' or '!' are performed, the modified line shall be written to the standard output before command is executed. The! command shall write:
"! \(\backslash n "\)
to standard output upon completion, unless the -s option is specified. The current line number shall be unchanged.

\section*{Null Command}

Synopsis: (.+1)
An address alone on a line shall cause the addressed line to be written. A <newline> alone shall be equivalent to " +1 p ". The current line number shall be set to the address of the written line.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion without any file or command errors.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

When an error in the input script is encountered, or when an error is detected that is a consequence of the data (not) present in the file or due to an external condition such as a read or write error:
- If the standard input is a terminal device file, all input shall be flushed, and a new command read.
- If the standard input is a regular file, ed shall terminate with a non-zero exit status.

\section*{APPLICATION USAGE}

Because of the extremely terse nature of the default error messages, the prudent script writer begins the \(e d\) input commands with an \(\mathbf{H}\) command, so that if any errors do occur at least some clue as to the cause is made available.

In previous versions, an obsolescent - option was described. This is no longer specified. Applications should use the -s option. Using - as a file operand now produces unspecified results. This allows implementations to continue to support the former required behavior.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The initial description of this utility was adapted from the SVID. It contains some features not found in Version 7 or BSD-derived systems. Some of the differences between the POSIX and BSD ed utilities include, but need not be limited to:
- The BSD - option does not suppress the ' !' prompt after a ! command.
- BSD does not support the special meanings of the '\%' and '!' characters within a! command.
- BSD does not support the addresses ';' and ','.
- BSD allows the command/suffix pairs pp, 11, and so on, which are unspecified in this volume of IEEE Std 1003.1-200x.
- BSD does not support the ' !' character part of the \(\mathbf{e}, \mathbf{r}\), or \(\mathbf{w}\) commands.
- A failed \(\mathbf{g}\) command in BSD sets the line number to the last line searched if there are no matches.
- BSD does not default the command list to the \(\mathbf{p}\) command.
- BSD does not support the \(\mathbf{G}, \mathbf{h}, \mathbf{H}, \mathbf{n}\), or \(\mathbf{V}\) commands.
- On BSD, if there is no inserted text, the insert command changes the current line to the referenced line -1 ; that is, the line before the specified line.
- On BSD, the join command with only a single address changes the current line to that address.
- BSD does not support the \(\mathbf{P}\) command; moreover, in BSD it is synonymous with the \(\mathbf{p}\) command.
- BSD does not support the undo of the commands \(\mathbf{j}, \mathbf{m}, \mathbf{r}, \mathbf{s}\), or \(\mathbf{t}\).
- The Version 7 ed command \(\mathbf{W}\), and the BSD ed commands \(\mathbf{W}\), wq, and \(\mathbf{z}\) are not present in this volume of IEEE Std 1003.1-200x.

The -s option was added to allow the functionality of the now withdrawn - option in a manner compatible with the Utility Syntax Guidelines.
In early proposals there was a limit, \{ED_FILE_MAX\}, that described the historical limitations of some ed utilities in their handling of large files; some of these have had problems with files larger than 100000 bytes. It was this limitation that prompted much of the desire to include a split command in this volume of IEEE Std 1003.1-200x. Since this limit was removed, this volume of IEEE Std 1003.1-200x requires that implementations document the file size limits imposed by ed in the conformance document. The limit \(\left\{E D \_L I N E \_M A X\right\}\) was also removed; therefore, the global limit \{LINE_MAX\} is used for input and output lines.

The manner in which the 1 command writes non-printable characters was changed to avoid the historical backspace-overstrike method. On video display terminals, the overstrike is ambiguous because most terminals simply replace overstruck characters, making the \(\mathbf{l}\) format not useful for its intended purpose of unambiguously understanding the content of the line. The historical backslash escapes were also ambiguous. (The string " \(a \backslash 0011\) " could represent a line containing those six characters or a line containing the three characters ' \(a\) ', a byte with a binary value of 1 , and a 1.) In the format required here, a backslash appearing in the line is written as " \(\backslash \backslash\) " so that the output is truly unambiguous. The method of marking the ends of lines was adopted from the ex editor and is required for any line ending in <space>s; the ' \(\$^{\prime}\) is placed on all lines so that a real ' \$' at the end of a line cannot be misinterpreted.

Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

The description of how a NUL is written was removed. The NUL character cannot be in text files, and this volume of IEEE Std 1003.1-200x should not dictate behavior in the case of undefined, erroneous input.
Unlike some of the other editing utilities, the filenames accepted by the \(\mathbf{E}, \mathbf{e}, \mathbf{R}\), and \(\mathbf{r}\) commands are not patterns.
Early proposals stated that the -p option worked only when standard input was associated with a terminal device. This has been changed to conform to historical implementations, thereby allowing applications to interpose themselves between a user and the ed utility.
The form of the substitute command that uses the \(\mathbf{n}\) suffix was limited in some historical documentation (where this was described incorrectly as "backreferencing"). This limit has been omitted because there is no reason why an editor processing lines of \{LINE_MAX\} length should have this restriction. The command \(s / x / X / 2047\) should be able to substitute the 2047 th occurrence of ' \(x\) ' on a line.

The use of printing commands with printing suffixes (such as \(\mathbf{p n}, \mathbf{l p}\), and so on) was made unspecified because BSD-based systems allow this, whereas System V does not.
Some BSD-based systems exit immediately upon receipt of end-of-file if all of the lines in the file have been deleted. Since this volume of IEEE Std 1003.1-200x refers to the \(\mathbf{q}\) command in this
instance, such behavior is not allowed.
Some historical implementations returned exit status zero even if command errors had occurred; this is not allowed by this volume of IEEE Std 1003.1-200x.

Some historical implementations contained a bug that allowed a single period to be entered in input mode as <backslash> <period> <newline>. This is not allowed by ed because there is no description of escaping any of the characters in input mode; backslashes are entered into the buffer exactly as typed. The typical method of entering a single period has been to precede it with another character and then use the substitute command to delete that character.

It is difficult under some modes of some versions of historical operating system terminal drivers to distinguish between an end-of-file condition and terminal disconnect. IEEE Std 1003.1-200x does not require implementations to distinguish between the two situations, which permits historical implementations of the ed utility on historical platforms to conform. Implementations are encouraged to distinguish between the two, if possible, and take appropriate action on terminal disconnect.

Historically, ed accepted a zero address for the a and rcommands in order to insert text at the start of the edit buffer. When the buffer was empty the command .= returned zero. IEEE Std 1003.1-200x requires conformance to historical practice.

For consistency with the \(\mathbf{a}\) and \(\mathbf{r}\) commands and better user functionality, the \(\mathbf{i}\) and \(\mathbf{c}\) commands must also accept an address of 0 , in which case \(0 i\) is treated as \(1 i\) and likewise for the \(\mathbf{c}\) command.

All of the following are valid addresses:
\begin{tabular}{ll}
+++ & Three lines after the current line. \\
/pattern/- & One line before the next occurrence of pattern. \\
-2 & Two lines before the current line. \\
\(3----2\) & Line one (note the intermediate negative address)
\end{tabular}

123 Line six.
Any number of addresses can be provided to commands taking addresses; for example, " \(1,2,3,4,5 \mathrm{p}\) " prints lines 4 and 5, because two is the greatest valid number of addresses accepted by the print command. This, in combination with the semicolon delimiter, permits users to create commands based on ordered patterns in the file. For example, the command " 3 ; /foo/ ; +2p" will display the first line after line 3 that contains the pattern foo, plus the next two lines. Note that the address " \(3 ;\) " must still be evaluated before being discarded, because the search origin for the " \(/\) foo/" command depends on this.
Historically, ed disallowed address chains, as discussed above, consisting solely of comma or semicolon separators; for example, ", , , " or "; ; ; " were considered an error. For consistency of address specification, this restriction is removed. The following table lists some of the address forms now possible:
\begin{tabular}{|c|c|c|c|c|}
\hline Address & Addr1 & Addr2 & Status & Comment \\
\hline 7, & 7 & 7 & Historical & \\
\hline 7,5, & 5 & 5 & Historical & \\
\hline 7,5,9 & 5 & 9 & Historical & \\
\hline 7,9 & 7 & 9 & Historical & \\
\hline 7, + & 7 & 8 & Historical & \\
\hline , & 1 & \$ & Historical & \\
\hline , 7 & 1 & 7 & Extension & \\
\hline ', & \$ & \$ & Extension & \\
\hline , ; & \$ & \$ & Extension & \\
\hline 7; & 7 & 7 & Historical & \\
\hline 7; 5; & 5 & 5 & Historical & \\
\hline 7;5;9 & 5 & 9 & Historical & \\
\hline 7;5,9 & 5 & 9 & Historical & \\
\hline 7; \$; 4 & \$ & 4 & Historical & Valid, but erroneous. \\
\hline 7;9 & 7 & 9 & Historical & \\
\hline 7; + & 7 & 8 & Historical & \\
\hline ; & - & \$ & Historical & \\
\hline ; 7 & - & 7 & Extension & \\
\hline ; ; & \$ & \$ & Extension & \\
\hline ; & \$ & \$ & Extension & \\
\hline
\end{tabular}

Historically, values could be added to addresses by including them after one or more <blank>s; for example, " \(3-5 p\) " wrote the seventh line of the file, and "/foo/ 5" was the same as " 5 /foo/". However, only absolute values could be added; for example, " 5 /foo/" was an error. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, ed accepted the \(\quad\) ^' character as an address, in which case it was identical to the hyphen character. IEEE Std 1003.1-200x does not require or prohibit this behavior.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}

Section 1.11 (on page 18), ex, sed, sh, vi, the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, Modem Disconnect and Closing a Device Terminal

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
In the OPTIONS section, the meaning of \(-\mathbf{s}\) and - is clarified.
A second FUTURE DIRECTION is added.
Issue 6
The obsolescent single-minus form is removed.
A second APPLICATION USAGE note is added.
The Open Group Corrigendum U025/2 is applied, correcting the description of the Edit section.
The ed utility is updated to align with the IEEE P1003.2b draft standard. This includes addition of the treatment of the SIGQUIT signal, changes to ed addressing, and changes to processing when end-of-file is detected and when terminal disconnect is detected.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/22 is applied, adding the text: "Any line modified by the command list shall be unmarked." to the G command. This change corresponds
to a similar change made to the \(\mathbf{g}\) command in the first version of IEEE Std 1003.1-200x.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/7 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying the behavior if an operand is ' -'.

Austin Group Interpretation 1003.1-2001 \#036 is applied, clarifying the behavior for BREs.
SD5-XCU-ERN-94 is applied, updating text in the EXTENDED DESCRIPTION where a terminal disconnect is detected (in Commands in ed).

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
env - set the environment for command invocation

\section*{SYNOPSIS}
```

env [-i] [name=value]... [utility [argument...]]

```

\section*{DESCRIPTION}

The env utility shall obtain the current environment, modify it according to its arguments, then invoke the utility named by the utility operand with the modified environment.

Optional arguments shall be passed to utility.
If no utility operand is specified, the resulting environment shall be written to the standard output, with one name=value pair per line.
If the first argument is \({ }^{\prime}-^{\prime}\), the results are unspecified.

\section*{OPTIONS}

The env utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for the unspecified usage of \({ }^{\prime}-\) '.

The following options shall be supported:
-i Invoke utility with exactly the environment specified by the arguments; the inherited environment shall be ignored completely.

OPERANDS
The following operands shall be supported:
name=value Arguments of the form name=value shall modify the execution environment, and shall be placed into the inherited environment before the utility is invoked.
utility The name of the utility to be invoked. If the utility operand names any of the special built-in utilities in Section 2.14 (on page 64), the results are undefined.
argument A string to pass as an argument for the invoked utility.
STDIN
Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of env:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
\begin{tabular}{lll}
13766 & NSI & NLSPATH \\
13767 & PATH & Determine the location of message catalogs for the processing of LC_MESSAGES. \\
13768 & & Determine the location of the \(u t i l i t y\), as described in the Base Definitions volume of \\
13769 & & IEEE Std 1003.1-200x, Chapter 8, Environment Variables. If PATH is specified as a \\
name=value operand to \(e n v\), the value given shall be used in the search for utility.
\end{tabular}

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

If no utility operand is specified, each name=value pair in the resulting environment shall be written in the form:
"\%s=\%s\n", <name>, <value>
If the utility operand is specified, the env utility shall not write to standard output.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

If utility is invoked, the exit status of env shall be the exit status of utility; otherwise, the env utility shall exit with one of the following values:

0 The env utility completed successfully.
1-125 An error occurred in the env utility.
126 The utility specified by utility was found but could not be invoked.
127 The utility specified by utility could not be found.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

Historical implementations of the env utility use the execvp () or \(\operatorname{execlp}()\) functions defined in the System Interfaces volume of IEEE Std 1003.1-200x to invoke the specified utility; this provides better performance and keeps users from having to escape characters with special meaning to the shell. Therefore, shell functions, special built-ins, and built-ins that are only provided by the shell are not found.

\section*{EXAMPLES}

The following command:
```

env -i PATH=/mybin mygrep xyz myfile

```
invokes the command mygrep with a new PATH value as the only entry in its environment. In this case, PATH is used to locate mygrep, which then must reside in /mybin.

\section*{RATIONALE}

As with all other utilities that invoke other utilities, this volume of IEEE Std 1003.1-200x only specifies what env does with standard input, standard output, standard error, input files, and output files. If a utility is executed, it is not constrained by the specification of input and output by env.
The -i option was added to allow the functionality of the withdrawn - option in a manner compatible with the Utility Syntax Guidelines. It is possible to create a non-conforming environment using the -i option, as it may remove environment variables required by the implementation for conformance. The following will preserve these environment variables as well as preserve the PATH for conforming utilities:
```

IFS='
r

# The preceding value should be <space><tab><newline>.

# Set IFS to its default value.

set -f

# disable pathname expansion

\unalias -a

# Unset all possible aliases.

# Note that unalias is escaped to prevent an alias

# being used for unalias.

# This step is not strictly necessary, since aliases are not inherited,

# and the ENV environment variable is only used by interactive shells,

# the only way any aliases can exist in a script is if it defines them

# itself.

unset -f env getconf

# Ensure env and getconf are not user functions.

env -i $(getconf V7_ENV) PATH="$(getconf PATH)" command

```

Some have suggested that env is redundant since the same effect is achieved by:
```

name=value ... utility [ argument ... ]

```

The example is equivalent to env when an environment variable is being added to the environment of the command, but not when the environment is being set to the given value. The env utility also writes out the current environment if invoked without arguments. There is sufficient functionality beyond what the example provides to justify inclusion of env.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{Issue 7}

Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying the behavior if the first argument is \({ }^{\prime}-{ }^{\prime}\).
Austin Group Interpretation 1003.1-2001 \#047 is applied, providing RATIONALE on how to use the env utiilty to preserve a conforming environment.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

\section*{NAME}
ex - text editor

\section*{SYNOPSIS}

UP ex [-rR] [-s|-v] [-c command] [-t tagstring] [-w size] [file...]

\section*{DESCRIPTION}

The \(e x\) utility is a line-oriented text editor. There are two other modes of the editor-open and visual-in which screen-oriented editing is available. This is described more fully by the ex open and visual commands and in \(v i\).
If an operand is ' - ', the results are unspecified.
This section uses the term edit buffer to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.
Certain terminals do not have all the capabilities necessary to support the complete ex definition, such as the full-screen editing commands (visual mode or open mode). When these commands cannot be supported on such terminals, this condition shall not produce an error message such as "not an editor command" or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of IEEE Std 1003.1-200x or report an error describing the terminal-related deficiency.

\section*{OPTIONS}

The \(e x\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for the unspecified usage of ' - ', and that ' + ' may be recognized as an option deliminter as well as \({ }^{\prime}{ }^{\prime}\).
The following options shall be supported:
-c command Specify an initial command to be executed in the first edit buffer loaded from an existing file (see the EXTENDED DESCRIPTION section). Implementations may support more than a single -c option. In such implementations, the specified commands shall be executed in the order specified on the command line.
-r Recover the named files (see the EXTENDED DESCRIPTION section). Recovery information for a file shall be saved during an editor or system crash (for example, when the editor is terminated by a signal which the editor can catch), or after the use of an ex preserve command.
A crash in this context is an unexpected failure of the system or utility that requires restarting the failed system or utility. A system crash implies that any utilities running at the time also crash. In the case of an editor or system crash, the number of changes to the edit buffer (since the most recent preserve command) that will be recovered is unspecified.
If no file operands are given and the \(-\mathbf{t}\) option is not specified, all other options, the EXINIT variable, and any .exrc files shall be ignored; a list of all recoverable files available to the invoking user shall be written, and the editor shall exit normally without further action.
-R Set readonly edit option.

-s Prepare ex for batch use by taking the following actions:
- Suppress writing prompts and informational (but not diagnostic) messages.
- Ignore the value of TERM and any implementation default terminal type and assume the terminal is a type incapable of supporting open or visual modes; see the visual command and the description of \(v i\).
- Suppress the use of the EXINIT environment variable and the reading of any .exrc file; see the EXTENDED DESCRIPTION section.
- Suppress autoindentation, ignoring the value of the autoindent edit option.
\(-\mathbf{t}\) tagstring Edit the file containing the specified tagstring; see ctags. The tags feature represented by \(-\mathbf{t}\) tagstring and the tag command is optional. It shall be provided on any system that also provides a conforming implementation of ctags; otherwise, the use of \(-\mathbf{t}\) produces undefined results. On any system, it shall be an error to specify more than a single \(-\mathbf{t}\) option.
-v Begin in visual mode (see vi).
\(-\mathbf{w}\) size \(\quad\) Set the value of the window editor option to size.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a file to be edited.

\section*{STDIN}

The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section. The implementation may limit each line of standard input to a length of \{LINE_MAX\}.
If the standard input is not a terminal device, it shall be as if the \(-\mathbf{s}\) option had been specified.
If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

\section*{INPUT FILES}

Input files shall be text files or files that would be text files except for an incomplete last line that is not longer than \{LINE_MAX\}-1 bytes in length and contains no NUL characters. By default, any incomplete last line shall be treated as if it had a trailing <newline>. The editing of other forms of files may optionally be allowed by ex implementations.
The .exrc files and source files shall be text files consisting of ex commands; see the EXTENDED DESCRIPTION section.
By default, the editor shall read lines from the files to be edited without interpreting any of those lines as any form of editor command.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(e x\) :
COLUMNS Override the system-selected horizontal screen size. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.
EXINIT Determine a list of ex commands that are executed on editor start-up. See the EXTENDED DESCRIPTION section for more details of the initialization phase.
HOME Determine a pathname of a directory that shall be searched for an editor start-up file named .exrc; see the EXTENDED DESCRIPTION section.
\begin{tabular}{|c|c|c|c|}
\hline 13943 & & \multirow[t]{4}{*}{LANG} & Provide a default value for the internationalization variables that are unset or null. \\
\hline 13944 & & & (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, \\

\hline 13962 & & & \\
\hline 13963 & & & \\
\hline 13964 & XSI & NLSPATH & Determine the location of message catalogs for the processing of LC_MESSAGES. \\
\hline 13965 & & \multirow[t]{3}{*}{PATH} & \multirow[t]{3}{*}{Determine the search path for the shell command specified in the ex editor commands !, shell, read, and write, and the open and visual mode command !; see the description of command search and execution in Section 2.9.1.1 (on page 48).} \\
\hline 13966 & & & \\
\hline \multicolumn{2}{|l|}{13967} & & \\
\hline 13968 & & \multirow[t]{4}{*}{SHELL} & \multirow[t]{2}{*}{Determine the preferred command line interpreter for use as the default value of the shell edit option.} \\
\hline 13969 & & & \\
\hline 13970 & & & Determine the name of the terminal type. If this variable is unset or null, an \\
\hline 13971 & & & unspecified default terminal type shall be used. \\
\hline
\end{tabular}

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.

Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions. characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, the classification of characters as uppercase or lowercase letters, the case conversion of letters, and the detection of word boundaries.

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

\section*{ASYNCHRONOUS EVENTS}

The following term is used in this and following sections to specify command and asynchronous event actions:
complete write
A complete write is a write of the entire contents of the edit buffer to a file of a type other than a terminal device, or the saving of the edit buffer caused by the user executing the ex preserve command. Writing the contents of the edit buffer to a temporary file that will be removed when the editor exits shall not be considered a complete write.

The following actions shall be taken upon receipt of signals:
SIGINT If the standard input is not a terminal device, \(e x\) shall not write the file or return to command or text input mode, and shall exit with a non-zero exit status.

Otherwise, if executing an open or visual text input mode command, ex in receipt of SIGINT shall behave identically to its receipt of the \(<\) ESC \(>\) character.
Otherwise:
1. If executing an ex text input mode command, all input lines that have been completely entered shall be resolved into the edit buffer, and any partially entered line shall be discarded.
2. If there is a currently executing command, it shall be aborted and a message displayed. Unless otherwise specified by the ex or vi command descriptions, it is unspecified whether any lines modified by the executing command appear modified, or as they were before being modified by the executing command, in the buffer.

If the currently executing command was a motion command, its associated command shall be discarded.
3. If in open or visual command mode, the terminal shall be alerted.
4. The editor shall then return to command mode.

SIGCONT
SIGHUP
The screen shall be refreshed if in open or visual mode.
If the edit buffer has been modified since the last complete write, ex shall attempt to save the edit buffer so that it can be recovered later using the -r option or the ex recover command. The editor shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

SIGTERM
Refer to SIGHUP.

The action taken for all other signals is unspecified.

\section*{STDOUT}

The standard output shall be used only for writing prompts to the user, for informational messages, and for writing lines from the file.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

The output from ex shall be text files.

\section*{EXTENDED DESCRIPTION}

Only the ex mode of the editor is described in this section. See vi for additional editing capabilities available in \(e x\).

When an error occurs, ex shall write a message. If the terminal supports a standout mode (such as inverse video), the message shall be written in standout mode. If the terminal does not support a standout mode, and the edit option errorbells is set, an alert action shall precede the error message.
By default, ex shall start in command mode, which shall be indicated by a : prompt; see the prompt command. Text input mode can be entered by the append, insert, or change commands; it can be exited (and command mode re-entered) by typing a period \(\left({ }^{\prime} .^{\prime}\right)\) alone at the beginning of a line.

\section*{Initialization in ex and vi}

The following symbols are used in this and following sections to specify locations in the edit buffer:

\section*{alternate and current pathnames}

Two pathnames, named current and alternate, are maintained by the editor. Any ex commands that take filenames as arguments shall set them as follows:
1. If a file argument is specified to the ex edit, ex, or recover commands, or if an ex tag 14031 command replaces the contents of the edit buffer.
a. If the command replaces the contents of the edit buffer, the current pathname shall be set to the file argument or the file indicated by the tag, and the alternate pathname shall be set to the previous value of the current pathname.
b. Otherwise, the alternate pathname shall be set to the file argument.
2. If a file argument is specified to the ex next command:
a. If the command replaces the contents of the edit buffer, the current pathname shall be set to the first file argument, and the alternate pathname shall be set to the previous value of the current pathname.
3. If a file argument is specified to the \(e x\) file command, the current pathname shall be set to the file argument, and the alternate pathname shall be set to the previous value of the current pathname.
4. If a file argument is specified to the ex read and write commands (that is, when reading or writing a file, and not to the program named by the shell edit option), or a file argument is specified to the ex xit command:
a. If the current pathname has no value, the current pathname shall be set to the file argument.
b. Otherwise, the alternate pathname shall be set to the file argument.

If the alternate pathname is set to the previous value of the current pathname when the current pathname had no previous value, then the alternate pathname shall have no value as a result.
current line
The line of the edit buffer referenced by the cursor. Each command description specifies the current line after the command has been executed, as the current line value. When the edit buffer contains no lines, the current line shall be zero; see Addressing in ex (on page 363).
current column
The current display line column occupied by the cursor. (The columns shall be numbered beginning at 1.) Each command description specifies the current column after the command has been executed, as the current column value. This column is an ideal column that is remembered over the lifetime of the editor. The actual display line column upon which the cursor rests may be different from the current column; see the cursor positioning discussion in Command Descriptions in vi (on page 994).
set to non-<blank>
A description for a current column value, meaning that the current column shall be set to the last display line column on which is displayed any part of the first non-<blank> of the line. If the line has no non-<blank> non-<newline>s, the current column shall be set to the last display line column on which is displayed any part of the last non-<newline> in the line. If the line is empty, the current column shall be set to column position 1.
The length of lines in the edit buffer may be limited to \{LINE_MAX\} bytes. In open and visual mode, the length of lines in the edit buffer may be limited to the number of characters that will fit in the display. If either limit is exceeded during editing, an error message shall be written. If either limit is exceeded by a line read in from a file, an error message shall be written and the edit session may be terminated.
If the editor stops running due to any reason other than a user command, and the edit buffer has been modified since the last complete write, it shall be equivalent to a SIGHUP asynchronous event. If the system crashes, it shall be equivalent to a SIGHUP asynchronous event.

During initialization (before the first file is copied into the edit buffer or any user commands from the terminal are processed) the following shall occur:
1. If the environment variable EXINIT is set, the editor shall execute the ex commands contained in that variable.
2. If the EXINIT variable is not set, and all of the following are true:
a. The HOME environment variable is not null and not empty.
b. The file .exrc in the directory referred to by the HOME environment variable:
1. Exists
2. Is owned by the same user ID as the real user ID of the process or the process has appropriate privileges
3. Is not writable by anyone other than the owner
the editor shall execute the ex commands contained in that file.
3. If and only if all of the following are true:
a. The current directory is not referred to by the HOME environment variable.
b. A command in the EXINIT environment variable or a command in the .exrc file in the directory referred to by the HOME environment variable sets the editor option exrc.
c. The .exrc file in the current directory:
1. Exists
2. Is owned by the same user ID as the real user ID of the process, or by one of a set of implementation-defined user IDs
3. Is not writable by anyone other than the owner
the editor shall attempt to execute the ex commands contained in that file.
Lines in any exrc file that are blank lines shall be ignored. If any .exrc file exists, but is not read for ownership or permission reasons, it shall be an error.

After the EXINIT variable and any .exrc files are processed, the first file specified by the user shall be edited, as follows:
1. If the user specified the -t option, the effect shall be as if the \(e x\) tag command was entered with the specified argument, with the exception that if tag processing does not result in a file to edit, the effect shall be as described in step 3. below.
2. Otherwise, if the user specified any command line file arguments, the effect shall be as if the ex edit command was entered with the first of those arguments as its file argument.
3. Otherwise, the effect shall be as if the ex edit command was entered with a nonexistent filename as its file argument. It is unspecified whether this action shall set the current pathname. In an implementation where this action does not set the current pathname, any editor command using the current pathname shall fail until an editor command sets the current pathname.

If the \(-\mathbf{r}\) option was specified, the first time a file in the initial argument list or a file specified by the \(-\mathbf{t}\) option is edited, if recovery information has previously been saved about it, that information shall be recovered and the editor shall behave as if the contents of the edit buffer have already been modified. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. If no recovery information about a file
is available, an informational message to this effect shall be written, and the edit shall proceed as usual.

If the -c option was specified, the first time a file that already exists (including a file that might not exist but for which recovery information is available, when the \(-\mathbf{r}\) option is specified) replaces or initializes the contents of the edit buffer, the current line shall be set to the last line of the edit buffer, the current column shall be set to non-<blank>, and the ex commands specified with the -c option shall be executed. In this case, the current line and current column shall not be set as described for the command associated with the replacement or initialization of the edit buffer contents. However, if the \(-\mathbf{t}\) option or a tag command is associated with this action, the -c option commands shall be executed and then the movement to the tag shall be performed.

The current argument list shall initially be set to the filenames specified by the user on the command line. If no filenames are specified by the user, the current argument list shall be empty. If the \(-\mathbf{t}\) option was specified, it is unspecified whether any filename resulting from tag processing shall be prepended to the current argument list. In the case where the filename is added as a prefix to the current argument list, the current argument list reference shall be set to that filename. In the case where the filename is not added as a prefix to the current argument list, the current argument list reference shall logically be located before the first of the filenames specified on the command line (for example, a subsequent ex next command shall edit the first filename from the command line). If the \(-\mathbf{t}\) option was not specified, the current argument list reference shall be to the first of the filenames on the command line.

\section*{Addressing in ex}

Addressing in ex relates to the current line and the current column; the address of a line is its 1-based line number, the address of a column is its 1-based count from the beginning of the line. Generally, the current line is the last line affected by a command. The current line number is the address of the current line. In each command description, the effect of the command on the current line number and the current column is described.

Addresses are constructed as follows:
1. The character \({ }^{\prime}\) (period) shall address the current line.
2. The character ' \$ shall address the last line of the edit buffer.
3. The positive decimal number \(n\) shall address the \(n\)th line of the edit buffer.
4. The address "' x " refers to the line marked with the mark name character ' x ', which shall be a lowercase letter from the portable character set or one of the characters ' ' ' or \(\prime^{\prime \prime}\). It shall be an error if the line that was marked is not currently present in the edit buffer or the mark has not been set. Lines can be marked with the ex mark or \(\mathbf{k}\) commands, or the \(v i \mathrm{~m}\) command.
5. A regular expression enclosed by slashes ( \(\prime^{\prime}\) ) shall address the first line found by searching forwards from the line following the current line toward the end of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. As stated in Regular Expressions in ex (on page 392), an address consisting of a null regular expression delimited by slashes "//" shall address the next line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second slash can be omitted at the end of a command line. If the wrapscan edit option is set, the search shall wrap around to the beginning of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence " \(\backslash /\) " shall represent a literal slash instead of the regular expression delimiter.
6. A regular expression enclosed in question marks (' \({ }^{\prime}\) ') shall address the first line found by searching backwards from the line preceding the current line toward the beginning of the edit buffer and stopping at the first line for which the line excluding the terminating <newline> matches the regular expression. An address consisting of a null regular expression delimited by question marks "??" shall address the previous line for which the line excluding the terminating <newline> matches the last regular expression encountered. In addition, the second question mark can be omitted at the end of a command line. If the wrapscan edit option is set, the search shall wrap around from the beginning of the edit buffer to the end of the edit buffer and continue up to and including the current line, so that the entire edit buffer is searched. Within the regular expression, the sequence " \(\backslash\) ? " shall represent a literal question mark instead of the RE delimiter.
7. A plus sign \(\left(\prime^{\prime}+^{\prime}\right)\) or a minus sign \(\left(\prime^{\prime}\right)\) followed by a decimal number shall address the current line plus or minus the number. \(A^{\prime}+{ }^{\prime}\) or \({ }^{\prime}-^{\prime}\) not followed by a decimal number shall address the current line plus or minus 1.
Addresses can be followed by zero or more address offsets, optionally <blank>-separated. Address offsets are constructed as follows:
1. A \({ }^{\prime}+{ }^{\prime}\) or \({ }^{\prime} \mathbf{I}^{\prime}\) immediately followed by a decimal number shall add (subtract) the indicated number of lines to (from) the address. \(\mathrm{A}^{\prime}+^{\prime}\) or \({ }^{\prime}-^{\prime}\) not followed by a decimal number shall add (subtract) 1 to (from) the address.
2. A decimal number shall add the indicated number of lines to the address.

It shall not be an error for an intermediate address value to be less than zero or greater than the last line in the edit buffer. It shall be an error for the final address value to be less than zero or greater than the last line in the edit buffer.
Commands take zero, one, or two addresses; see the descriptions of \(1 a d d r\) and \(2 a d d r\) in Command Descriptions in ex (on page 370). If more than the required number of addresses are provided to a command that requires zero addresses, it shall be an error. Otherwise, if more than the required number of addresses are provided to a command, the addresses specified first shall be evaluated and then discarded until the maximum number of valid addresses remain.

Addresses shall be separated from each other by a comma ( \({ }^{\prime}, \prime^{\prime}\) ) or a semicolon ( \({ }^{\prime} ;^{\prime}\) ). If no address is specified before or after a comma or semicolon separator, it shall be as if the address of the current line was specified before or after the separator. In the case of a semicolon separator, the current line \(\left({ }^{\prime} .{ }^{\prime}\right)\) shall be set to the first address, and only then will the next address be calculated. This feature can be used to determine the starting line for forwards and backwards searches (see rules 5. and 6.).
A percent sign ( \(\prime^{\circ \prime \prime}\) ) shall be equivalent to entering the two addresses " \(1, \$\).
Any delimiting <blank>s between addresses, address separators, or address offsets shall be discarded.

\section*{Command Line Parsing in ex}

The following symbol is used in this and following sections to describe parsing behavior:
escape If a character is referred to as "backslash-escaped" or "<control>-V-escaped," it shall mean that the character acquired or lost a special meaning by virtue of being preceded, respectively, by a backslash or <control>-V character. Unless otherwise specified, the escaping character shall be discarded at that time and shall not be further considered for any purpose.
Command-line parsing shall be done in the following steps. For each step, characters already evaluated shall be ignored; that is, the phrase "leading character" refers to the next character that has not yet been evaluated.
1. Leading colon characters shall be skipped.
2. Leading <blank>s shall be skipped.
3. If the leading character is a double-quote character, the characters up to and including the next non-backslash-escaped <newline> shall be discarded, and any subsequent characters shall be parsed as a separate command.
4. Leading characters that can be interpreted as addresses shall be evaluated; see Addressing in ex (on page 363).
5. Leading <blank>s shall be skipped.
6. If the next character is a vertical-line character or a <newline>:
a. If the next character is a <newline>:
1. If \(e x\) is in open or visual mode, the current line shall be set to the last address specified, if any.
2. Otherwise, if the last command was terminated by a vertical-line character, no action shall be taken; for example, the command " ||<newline>" shall execute two implied commands, not three.
3. Otherwise, step 6.b. shall apply.
b. Otherwise, the implied command shall be the print command. The last \#, p, and \(\mathbf{l}\) flags specified to any ex command shall be remembered and shall apply to this implied command. Executing the ex number, print, or list command shall set the remembered flags to \#, nothing, and 1, respectively, plus any other flags specified for that execution of the number, print, or list command.
If \(e x\) is not currently performing a global or \(\mathbf{v}\) command, and no address or count is specified, the current line shall be incremented by 1 before the command is executed. If incrementing the current line would result in an address past the last line in the edit buffer, the command shall fail, and the increment shall not happen.
c. The <newline> or vertical-line character shall be discarded and any subsequent characters shall be parsed as a separate command.
7. The command name shall be comprised of the next character (if the character is not alphabetic), or the next character and any subsequent alphabetic characters (if the character is alphabetic), with the following exceptions:
a. Commands that consist of any prefix of the characters in the command name delete, followed immediately by any of the characters ' \(l^{\prime},{ }^{\prime} \mathrm{p}^{\prime},{ }^{\prime}++^{\prime}, \prime^{\prime}\), or \({ }^{\prime} \#\) ' shall be interpreted as a delete command, followed by a <blank>, followed by the characters that were not part of the prefix of the delete command. The maximum number of characters shall be matched to the command name delete; for example, "del" shall not be treated as "de" followed by the flag 1.
b. Commands that consist of the character ' \(\mathrm{k}^{\prime}\), followed by a character that can be used as the name of a mark, shall be equivalent to the mark command followed by a <blank>, followed by the character that followed the ' \(\mathrm{k}^{\prime}\).
c. Commands that consist of the character ' \(s\) ', followed by characters that could be interpreted as valid options to the scommand, shall be the equivalent of the s command, without any pattern or replacement values, followed by a <blank>, followed by the characters after the ' \(s\) '.
8. The command name shall be matched against the possible command names, and a command name that contains a prefix matching the characters specified by the user shall be the executed command. In the case of commands where the characters specified by the
user could be ambiguous, the executed command shall be as follows:
\begin{tabular}{|l|l||l|l||l|l|}
\hline \(\mathbf{a}\) & append & n & next & \(\mathbf{t}\) & \(\mathbf{t}\) \\

ma & mark & s & s & & \\
\hline
\end{tabular}

Implementation extensions with names causing similar ambiguities shall not be checked for a match until all possible matches for commands specified by IEEE Std 1003.1-200x have been checked.
9. If the command is a! command, or if the command is a read command followed by zero or more <blank>s and a !, or if the command is a write command followed by one or more <blank>s and a !, the rest of the command shall include all characters up to a non-backslash-escaped <newline>. The <newline> shall be discarded and any subsequent characters shall be parsed as a separate ex command.
10. Otherwise, if the command is an edit, ex, or next command, or a visual command while in open or visual mode, the next part of the command shall be parsed as follows:
a. Any ' !' character immediately following the command shall be skipped and be part of the command.
b. Any leading <blank>s shall be skipped and be part of the command.
c. If the next character is a ' + ', characters up to the first non-backslash-escaped <newline> or non-backslash-escaped <blank> shall be skipped and be part of the command.
d. The rest of the command shall be determined by the steps specified in paragraph 12.
11. Otherwise, if the command is a global, open, s, or \(\mathbf{v}\) command, the next part of the command shall be parsed as follows:
a. Any leading <blank>s shall be skipped and be part of the command.
b. If the next character is not an alphanumeric, double-quote, <newline>, backslash, or vertical-line character:
1. The next character shall be used as a command delimiter.
2. If the command is a global, open, or \(\mathbf{v}\) command, characters up to the first non-backslash-escaped <newline>, or first non-backslash-escaped delimiter character, shall be skipped and be part of the command.
3. If the command is an s command, characters up to the first non-backslashescaped <newline>, or second non-backslash-escaped delimiter character, shall be skipped and be part of the command.
c. If the command is a global or \(\mathbf{v}\) command, characters up to the first non-backslashescaped <newline> shall be skipped and be part of the command.
d. Otherwise, the rest of the command shall be determined by the steps specified in paragraph 12.
12. Otherwise:
a. If the command was a map, unmap, abbreviate, or unabbreviate command, characters up to the first non-<control>-V-escaped <newline>, vertical-line, or double-quote character shall be skipped and be part of the command.
b. Otherwise, characters up to the first non-backslash-escaped <newline>, verticalline, or double-quote character shall be skipped and be part of the command.
c. If the command was an append, change, or insert command, and the step 12.b. ended at a vertical-line character, any subsequent characters, up to the next non-backslash-escaped <newline> shall be used as input text to the command.
d. If the command was ended by a double-quote character, all subsequent characters, up to the next non-backslash-escaped <newline>, shall be discarded.
e. The terminating <newline> or vertical-line character shall be discarded and any subsequent characters shall be parsed as a separate ex command.

Command arguments shall be parsed as described by the Synopsis and Description of each individual ex command. This parsing shall not be <blank>-sensitive, except for the ! argument, which must follow the command name without intervening <blank>s, and where it would otherwise be ambiguous. For example, count and flag arguments need not be <blank>-separated because "d22p" is not ambiguous, but file arguments to the ex next command must be separated by one or more <blank>s. Any <blank> in command arguments for the abbreviate, unabbreviate, map, and unmap commands can be <control>-V-escaped, in which case the <blank> shall not be used as an argument delimiter. Any <blank> in the command argument for any other command can be backslash-escaped, in which case that <blank> shall not be used as an argument delimiter.

Within command arguments for the abbreviate, unabbreviate, map, and unmap commands, any character can be <control>-V-escaped. All such escaped characters shall be treated literally and shall have no special meaning. Within command arguments for all other ex commands that are not regular expressions or replacement strings, any character that would otherwise have a special meaning can be backslash-escaped. Escaped characters shall be treated literally, without special meaning as shell expansion characters or \({ }^{\prime}\) !', \(\prime^{\prime} \circ\), and \({ }^{\prime} \#^{\prime}\) expansion characters. See Regular Expressions in ex and Replacement Strings in ex for descriptions of command arguments that are regular expressions or replacement strings.
Non-backslash-escaped \({ }^{\prime} \circ^{\prime}\) characters appearing in file arguments to any ex command shall be replaced by the current pathname; unescaped \({ }^{\prime} \#^{\prime}\) characters shall be replaced by the alternate pathname. It shall be an error if \({ }^{\prime} \%{ }^{\prime}\) or \({ }^{\prime} \#^{\prime}\) characters appear unescaped in an argument and their corresponding values are not set.

Non-backslash-escaped ' !' characters in the arguments to either the ex! command or the open and visual mode ! command, or in the arguments to the ex read command, where the first non-<blank> after the command name is a '!' character, or in the arguments to the ex write command where the command name is followed by one or more <blank>s and the first non-<blank> after the command name is a '!' character, shall be replaced with the arguments to the last of those three commands as they appeared after all unescaped \({ }^{\prime} \%{ }^{\prime}\), ' \#', and ' ! ' characters were replaced. It shall be an error if ' !' characters appear unescaped in one of these commands and there has been no previous execution of one of these commands.

If an error occurs during the parsing or execution of an ex command:
- An informational message to this effect shall be written. Execution of the ex command shall stop, and the cursor (for example, the current line and column) shall not be further modified.
- If the ex command resulted from a map expansion, all characters from that map expansion shall be discarded, except as otherwise specified by the map command.
- Otherwise, if the ex command resulted from the processing of an EXINIT environment variable, a .exrc file, a :source command, a -c option, or a +command specified to an ex edit, ex, next, or visual command, no further commands from the source of the commands shall be executed.
- Otherwise, if the \(e x\) command resulted from the execution of a buffer or a global or \(\mathbf{v}\) command, no further commands caused by the execution of the buffer or the global or \(\mathbf{v}\) command shall be executed.
- Otherwise, if the ex command was not terminated by a <newline>, all characters up to and including the next non-backslash-escaped <newline> shall be discarded.

\section*{Input Editing in ex}

The following symbol is used in this and the following sections to specify command actions:
word In the POSIX locale, a word consists of a maximal sequence of letters, digits, and underscores, delimited at both ends by characters other than letters, digits, or underscores, or by the beginning or end of a line or the edit buffer.
When accepting input characters from the user, in either ex command mode or ex text input mode, ex shall enable canonical mode input processing, as defined in the System Interfaces volume of IEEE Std 1003.1-200x.

If in \(e x\) text input mode:
1. If the number edit option is set, ex shall prompt for input using the line number that would be assigned to the line if it is entered, in the format specified for the ex number command.
2. If the autoindent edit option is set, ex shall prompt for input using autoindent characters, as described by the autoindent edit option. autoindent characters shall follow the line number, if any.
If in ex command mode:
1. If the prompt edit option is set, input shall be prompted for using a single ' :' character; otherwise, there shall be no prompt.
The input characters in the following sections shall have the following effects on the input line.

\section*{Scroll \\ Synopsis: eof}

See the description of the stty eof character in stty.
If in ex command mode:
If the eof character is the first character entered on the line, the line shall be evaluated as if it contained two characters: a <control>-D and a <newline>.
Otherwise, the eof character shall have no special meaning.
If in ex text input mode:

If the cursor follows an autoindent character, the autoindent characters in the line shall be modified so that a part of the next text input character will be displayed on the first column in the line after the previous shiftwidth edit option column boundary, and the user shall be prompted again for input for the same line.
Otherwise, if the cursor follows a ' 0 ', which follows an autoindent character, and the ' 0 ' was the previous text input character, the ' 0 ' and all autoindent characters in the line shall be discarded, and the user shall be prompted again for input for the same line.
Otherwise, if the cursor follows a \({ }^{\prime} \times\), which follows an autoindent character, and the \(\quad\) ' \(/\) ' was the previous text input character, the ' \(\quad\) ' and all autoindent characters in the line shall be discarded, and the user shall be prompted again for input for the same line. In addition, the autoindent level for the next input line shall be derived from the same line from which the autoindent level for the current input line was derived.
Otherwise, if there are no autoindent or text input characters in the line, the eof character shall be discarded.

Otherwise, the eof character shall have no special meaning.
<newline>
Synopsis: <newline>
<control>-J
If in ex command mode:
Cause the command line to be parsed; <control>-J shall be mapped to the <newline> for this purpose.

If in \(e x\) text input mode:
Terminate the current line. If there are no characters other than autoindent characters on the line, all characters on the line shall be discarded.

Prompt for text input on a new line after the current line. If the autoindent edit option is set, an appropriate number of autoindent characters shall be added as a prefix to the line as described by the ex autoindent edit option.
<backslash>
Synopsis: <backslash>
Allow the entry of a subsequent <newline> or <control>-J as a literal character, removing any special meaning that it may have to the editor during text input mode. The backslash character shall be retained and evaluated when the command line is parsed, or retained and included when the input text becomes part of the edit buffer.
```

<control>-V
Synopsis: <control>-V

```

Allow the entry of any subsequent character as a literal character, removing any special meaning that it may have to the editor during text input mode. The <control>-V character shall be discarded before the command line is parsed or the input text becomes part of the edit buffer.
If the "literal next" functionality is performed by the underlying system, it is implementationdefined whether a character other than <control>-V performs this function.
<control>-W
Synopsis: <control>-W
Discard the <control>-W, and the word previous to it in the input line, including any <blank>s following the word and preceding the <control>-W. If the "word erase" functionality is performed by the underlying system, it is implementation-defined whether a character other than <control>-W performs this function.

\section*{Command Descriptions in ex}

The following symbols are used in this section to represent command modifiers. Some of these modifiers can be omitted, in which case the specified defaults shall be used.
1addr A single line address, given in any of the forms described in Addressing in ex (on page 363 ); the default shall be the current line ( \(\left.{ }^{\prime} .^{\prime}\right)\), unless otherwise specified.
If the line address is zero, it shall be an error, unless otherwise specified in the following command descriptions.
If the edit buffer is empty, and the address is specified with a command other than \(=\), append, insert, open, put, read, or visual, or the address is not zero, it shall be an error.

2addr Two addresses specifying an inclusive range of lines. If no addresses are specified, the default for \(2 a d d r\) shall be the current line only (".,."), unless otherwise specified in the following command descriptions. If one address is specified, \(2 a d d r\) shall specify that line only, unless otherwise specified in the following command descriptions.
It shall be an error if the first address is greater than the second address.
If the edit buffer is empty, and the two addresses are specified with a command other than the!, write, wq, or xit commands, or either address is not zero, it shall be an error.
count A positive decimal number. If count is specified, it shall be equivalent to specifying an additional address to the command, unless otherwise specified by the following command descriptions. The additional address shall be equal to the last address specified to the command (either explicitly or by default) plus count-1.

If this would result in an address greater than the last line of the edit buffer, it shall be corrected to equal the last line of the edit buffer.
 can be <blank>-separated, and in any order or combination. The characters ' \#', ' \(p^{\prime}\), and ' \(l^{\prime}\) shall cause lines to be written in the format specified by the print command with the specified flags.
The lines to be written are as follows:
1. All edit buffer lines written during the execution of the ex \& , ~, list, number, open, print, s, visual, and z commands shall be written as specified by flags.
2. After the completion of an ex command with a flag as an argument, the current line shall be written as specified by flags, unless the current line was the last line written by the command.

The characters \({ }^{\prime}+{ }^{\prime}\) and \({ }^{\prime}-^{\prime}\) cause the value of the current line after the execution of the ex command to be adjusted by the offset address as described in Addressing in ex (on page 363). This adjustment shall occur before the current line is written as described in 2 . above.
\begin{tabular}{|c|c|c|}
\hline 14470 & & The default for flags shall be none. \\
\hline 471 & \multirow[t]{8}{*}{buffer} & One of a number of named areas for holding text. The named buffers are specified \\
\hline 14472 & & by the alphanumeric characters of the POSIX locale. There shall also be one \\
\hline 14473 & & "unnamed" buffer. When no buffer is specified for editor commands that use a \\
\hline 14474 & & buffer, the unnamed buffer shall be used. Commands that store text into buffers \\
\hline 14475 & & shall store the text as it was before the command took effect, and shall store text \\
\hline 14476 & & occurring earlier in the file before text occurring later in the file, regardless of how \\
\hline 14477 & & the text region was specified. Commands that store text into buffers shall store the \\
\hline 14478 & & text into the unnamed buffer as well as any specified buffer. \\
\hline 14479 & & In \(e x\) commands, buffer names are specified as the name by itself. In open or visual \\
\hline 14480 & & mode commands the name is preceded by a double quote ( \({ }^{\prime \prime}\) ') character. \\
\hline 14481 & & If the specified buffer name is an uppercase character, and the buffer contents are \\
\hline 14482 & & to be modified, the buffer shall be appended to rather than being overwritten. If \\
\hline 14483 & & the buffer is not being modified, specifying the buffer name in lowercase and \\
\hline 14484 & & uppercase shall have identical results. \\
\hline 14485 & & There shall also be buffers named by the numbers 1 through 9. In open and visual \\
\hline 14486 & & mode, if a region of text including characters from more than a single line is being \\
\hline 14487 & & modified by the vic ord commands, the motion character associated with the cor \\
\hline 14488 & & d commands specifies that the buffer text shall be in line mode, or the commands \\
\hline 14489 & & \%, \({ }^{\prime}, I, ?,(),, \mathbf{N}, \mathbf{n},\{\) or \(\}\) are used to define a region of text for the \(\mathbf{c}\) or \(\mathbf{d}\) commands, \\
\hline 14490 & & the contents of buffers 1 through 8 shall be moved into the buffer named by the \\
\hline 14491 & & next numerically greater value, the contents of buffer 9 shall be discarded, and the \\
\hline 14492 & & region of text shall be copied into buffer 1. This shall be in addition to copying the \\
\hline 14493 & & text into a user-specified buffer or unnamed buffer, or both. Numeric buffers can \\
\hline 14494 & & be specified as a source buffer for open and visual mode commands; however, \\
\hline 14495 & & specifying a numeric buffer as the write target of an open or visual mode \\
\hline 14496 & & command shall have unspecified results. \\
\hline 14497 & & The text of each buffer shall have the characteristic of being in either line or \\
\hline 14498 & & character mode. Appending text to a non-empty buffer shall set the mode to match \\
\hline 14499 & & the characteristic of the text being appended. Appending text to a buffer shall \\
\hline 14500 & & cause the creation of at least one additional line in the buffer. All text stored into \\
\hline 14501 & & buffers by ex commands shall be in line mode. The ex commands that use buffers \\
\hline 14502 & & as the source of text specify individually how buffers of different modes are \\
\hline 14503 & & handled. Each open or visual mode command that uses buffers for any purpose \\
\hline 14504 & & specifies individually the mode of the text stored into the buffer and how buffers \\
\hline 14505 & & of different modes are handled. \\
\hline 14506 & \multirow[t]{12}{*}{file} & Command text used to derive a pathname. The default shall be the current \\
\hline 14507 & & pathname, as defined previously, in which case, if no current pathname has yet \\
\hline 14508 & & been established it shall be an error, except where specifically noted in the \\
\hline 14509 & & individual command descriptions that follow. If the command text contains any of \\
\hline 14510 & &  \\
\hline 14511 & & subjected to the process of "shell expansions", as described below; if more than a \\
\hline 1451 & & single pathname results and the command expects only one, it shall be an error. \\
\hline 14513 & & The process of shell expansions in the editor shall be done as follows. The ex utility \\
\hline 14514 & & shall pass two arguments to the program named by the shell edit option; the first \\
\hline 14515 & & shall be -c, and the second shall be the string "echo" and the command text as a \\
\hline 14516 & & single argument. The standard output and standard error of that command shall \\
\hline 14517 & & replace the command text. \\
\hline
\end{tabular}
! A character that can be appended to the command name to modify its operation, as detailed in the individual command descriptions. With the exception of the ex read, write, and ! commands, the '!' character shall only act as a modifier if there are no <blank>s between it and the command name.

\section*{remembered search direction}

The vi commands \(\mathbf{N}\) and \(\mathbf{n}\) begin searching in a forwards or backwards direction in the edit buffer based on a remembered search direction, which is initially unset, and is set by the ex global, \(\mathbf{v}, \mathbf{s}\), and tag commands, and the \(v i /\) and ? commands.

\section*{Abbreviate}

Synopsis: ab[breviate][lhs rhs]
If \(l h s\) and \(r h s\) are not specified, write the current list of abbreviations and do nothing more.
Implementations may restrict the set of characters accepted in \(l h s\) or \(r h s\), except that printable characters and <blank>s shall not be restricted. Additional restrictions shall be implementationdefined.

In both \(l h s\) and \(r h s\), any character may be escaped with a <control>-V, in which case the character shall not be used to delimit \(l h s\) from \(r h s\), and the escaping <control>-V shall be discarded.

In open and visual text input mode, if a non-word or \(<\mathrm{ESC}>\) character that is not escaped by a <control>-V character is entered after a word character, a check shall be made for a set of characters matching lhs, in the text input entered during this command. If it is found, the effect shall be as if \(r\) hs was entered instead of \(l h s\).

The set of characters that are checked is defined as follows:
1. If there are no characters inserted before the word and non-word or <ESC> characters that triggered the check, the set of characters shall consist of the word character.
2. If the character inserted before the word and non-word or <ESC> characters that triggered the check is a word character, the set of characters shall consist of the characters inserted immediately before the triggering characters that are word characters, plus the triggering word character.
3. If the character inserted before the word and non-word or \(<E S C>\) characters that triggered the check is not a word character, the set of characters shall consist of the characters that were inserted before the triggering characters that are neither <blank>s nor word characters, plus the triggering word character.
It is unspecified whether the lhs argument entered for the ex abbreviate and unabbreviate commands is replaced in this fashion. Regardless of whether or not the replacement occurs, the effect of the command shall be as if the replacement had not occurred.
Current line: Unchanged.
Current column: Unchanged.

\section*{Append}

Synopsis: [1addr] a[ppend][!]
Enter ex text input mode; the input text shall be placed after the specified line. If line zero is specified, the text shall be placed at the beginning of the edit buffer.
This command shall be affected by the number and autoindent edit options; following the command name with '!' shall cause the autoindent edit option setting to be toggled for the duration of this command only.
Current line: Set to the last input line; if no lines were input, set to the specified line, or to the first
line of the edit buffer if a line of zero was specified, or zero if the edit buffer is empty.
Current column: Set to non-<blank>.

\section*{Arguments}

Synopsis: \(\quad \operatorname{ar}[g s]\)
Write the current argument list, with the current argument-list entry, if any, between ' [' and ' ]' characters.

Current line: Unchanged.
Current column: Unchanged.
Change
Synopsis: [2addr] c[hange][!][count]
Enter ex text input mode; the input text shall replace the specified lines. The specified lines shall be copied into the unnamed buffer, which shall become a line mode buffer.

This command shall be affected by the number and autoindent edit options; following the command name with ' !' shall cause the autoindent edit option setting to be toggled for the duration of this command only.
Current line: Set to the last input line; if no lines were input, set to the line before the first address, or to the first line of the edit buffer if there are no lines preceding the first address, or to zero if the edit buffer is empty.
Current column: Set to non-<blank>.
Change Directory
Synopsis: chd[ir][!][directory] cd[!][directory]

Change the current working directory to directory.
If no directory argument is specified, and the HOME environment variable is set to a non-null and non-empty value, directory shall default to the value named in the HOME environment variable. If the \(H O M E\) environment variable is empty or is undefined, the default value of directory is implementation-defined.
If no ' !' is appended to the command name, and the edit buffer has been modified since the last complete write, and the current pathname does not begin with a' \(/\), it shall be an error.
Current line: Unchanged.
Current column: Unchanged.
Copy
Synopsis: [2addr] co[py] laddr [flags] [2addr] t laddr [flags]

Copy the specified lines after the specified destination line; line zero specifies that the lines shall be placed at the beginning of the edit buffer.

Current line: Set to the last line copied.
Current column: Set to non-<blank>.
\begin{tabular}{|c|c|}
\hline 14600 & Delete \\
\hline 14601 & Synopsis: [2addr] d[elete][buffer][count][flags] \\

\hline 14627 & Current column: Set to non-<blank>. \\
\hline 14628 & Otherwise, if file is omitted or results in the current pathname: \\
\hline 14629 & Current line: Set to the first line of the edit buffer. \\
\hline 14630 & Current column: Set to non-<blank>. \\
\hline 14631
14632 & Otherwise, if file is the same as the last file edited, the line and column shall be set as follows; if the file was previously edited, the line and column may be set as follows: \\
\hline 14633 & \multirow[t]{2}{*}{Current line: Set to the last value held when that file was last edited. If this value is not a valid line in the new edit buffer, set to the first line of the edit buffer.} \\
\hline 14634 & \\
\hline 14635 & \multirow[t]{3}{*}{Current column: If the current line was set to the last value held when the file was last edited, set to the last value held when the file was last edited. Otherwise, or if the last value is not a valid column in the new edit buffer, set to non-<blank>.} \\
\hline 14636 & \\
\hline 14637 & \\
\hline 14638 & Otherwise: \\
\hline 14639 & Current line: Set to the first line of the edit buffer. \\
\hline 14640 & Current column: Set to non-<blank>. \\
\hline
\end{tabular}

File
Synopsis: f[ile][file]
If a file argument is specified, the alternate pathname shall be set to the current pathname, and the current pathname shall be set to file.

Write an informational message. If the file has a current pathname, it shall be included in this message; otherwise, the message shall indicate that there is no current pathname. If the edit buffer contains lines, the current line number and the number of lines in the edit buffer shall be included in this message; otherwise, the message shall indicate that the edit buffer is empty. If the edit buffer has been modified since the last complete write, this fact shall be included in this message. If the readonly edit option is set, this fact shall be included in this message. The message may contain other unspecified information.
Current line: Unchanged.
Current column: Unchanged.
Global
Synopsis: [2addr] g[lobal] /pattern/ [commands]
[2addr] v /pattern/ [commands]
The optional '!' character after the global command shall be the same as executing the \(\mathbf{v}\) command.

If pattern is empty (for example, "//") or not specified, the last regular expression used in the editor command shall be used as the pattern. The pattern can be delimited by slashes (shown in the Synopsis), as well as any non-alphanumeric or non-<blank> other than backslash, vertical line, double quote, or <newline>.
If no lines are specified, the lines shall default to the entire file.
The global and \(\mathbf{v}\) commands are logically two-pass operations. First, mark the lines within the specified lines for which the line excluding the terminating <newline> matches (global) or does not match (v or global!) the specified pattern. Second, execute the ex commands given by commands, with the current line (' \({ }^{\prime}\) ) set to each marked line. If an error occurs during this process, or the contents of the edit buffer are replaced (for example, by the ex :edit command) an error message shall be written and no more commands resulting from the execution of this command shall be processed.
Multiple ex commands can be specified by entering multiple commands on a single line using a vertical line to delimit them, or one per line, by escaping each <newline> with a backslash.
If no commands are specified:
1. If in \(e x\) command mode, it shall be as if the print command were specified.
2. Otherwise, no command shall be executed.

For the append, change, and insert commands, the input text shall be included as part of the command, and the terminating period can be omitted if the command ends the list of commands. The open and visual commands can be specified as one of the commands, in which case each marked line shall cause the editor to enter open or visual mode. If open or visual mode is exited using the \(v i \mathbf{Q}\) command, the current line shall be set to the next marked line, and open or visual mode reentered, until the list of marked lines is exhausted.
The global, \(\mathbf{v}\), and undo commands cannot be used in commands. Marked lines may be deleted by commands executed for lines occurring earlier in the file than the marked lines. In this case, no commands shall be executed for the deleted lines.
If the remembered search direction is not set, the global and \(\mathbf{v}\) commands shall set it to forward.

The autoprint and autoindent edit options shall be inhibited for the duration of the \(\mathbf{g}\) or \(\mathbf{v}\) command.

Current line: If no commands executed, set to the last marked line. Otherwise, as specified for the executed ex commands.

Current column: If no commands are executed, set to non-<blank>; otherwise, as specified for the individual ex commands.

\section*{Insert}

Synopsis: [1addr] i[nsert][!]
Enter ex text input mode; the input text shall be placed before the specified line. If the line is zero or 1 , the text shall be placed at the beginning of the edit buffer.
This command shall be affected by the number and autoindent edit options; following the command name with '!' shall cause the autoindent edit option setting to be toggled for the duration of this command only.
Current line: Set to the last input line; if no lines were input, set to the line before the specified line, or to the first line of the edit buffer if there are no lines preceding the specified line, or zero if the edit buffer is empty.

Current column: Set to non-<blank>.
Join
Synopsis: [2addr] j[oin][!][count][flags]
If count is specified:
If no address was specified, the join command shall behave as if 2addr were the current line and the current line plus count (., + + count \()\).
If one address was specified, the join command shall behave as if \(2 a d d r\) were the specified address and the specified address plus count (addr, addr + count ).
If two addresses were specified, the join command shall behave as if an additional address, equal to the last address plus count -1 (addr1,addr2,addr2 + count -1 ), was specified.

If this would result in a second address greater than the last line of the edit buffer, it shall be corrected to be equal to the last line of the edit buffer.

If no count is specified:
If no address was specified, the join command shall behave as if \(2 a d d r\) were the current line and the next line (.,,+1 ).
If one address was specified, the join command shall behave as if \(2 a d d r\) were the specified address and the next line ( \(a d d r, a d d r+1\) ).

Join the text from the specified lines together into a single line, which shall replace the specified lines.

If a '!' character is appended to the command name, the join shall be without modification of any line, independent of the current locale.
Otherwise, in the POSIX locale, set the current line to the first of the specified lines, and then, for each subsequent line, proceed as follows:
1. Discard leading <space>s from the line to be joined.
2. If the line to be joined is now empty, delete it, and skip steps 3 through 5 .
3. If the current line ends in a <blank>, or the first character of the line to be joined is a ' )' character, join the lines without further modification.
4. If the last character of the current line is a \({ }^{\prime} . .^{\prime}\), join the lines with two <space>s between them.
5. Otherwise, join the lines with a single <space> between them.

Current line: Set to the first line specified.
Current column: Set to non-<blank>.

\section*{List}

Synopsis: [2addr] l[ist][count][flags]
This command shall be equivalent to the ex command:
[2addr] p[rint][count] l[flags]
See Print (on page 381).
Map
Synopsis: map[!][lhs rhs]
If \(l h s\) and \(r h s\) are not specified:
1. If '!' is specified, write the current list of text input mode maps.
2. Otherwise, write the current list of command mode maps.
3. Do nothing more.

Implementations may restrict the set of characters accepted in lhs or rhs, except that printable characters and <blank>s shall not be restricted. Additional restrictions shall be implementationdefined. In both lhs and rhs, any character can be escaped with a <control>-V, in which case the character shall not be used to delimit lhs from rhs, and the escaping <control>-V shall be discarded.

If the character ' ! ' is appended to the map command name, the mapping shall be effective during open or visual text input mode rather than open or visual command mode. This allows lhs to have two different map definitions at the same time: one for command mode and one for text input mode.
For command mode mappings:

When the lhs is entered as any part of a vi command in open or visual mode (but not as part of the arguments to the command), the action shall be as if the corresponding rhs had been entered.

If any character in the command, other than the first, is escaped using a <control>-V character, that character shall not be part of a match to an lhs.

It is unspecified whether implementations shall support map commands where the \(l h s\) is more than a single character in length, where the first character of the lhs is printable.
If \(l h s\) contains more than one character and the first character is ' \(\#\) ', followed by a sequence of digits corresponding to a numbered function key, then when this function key is typed it shall be mapped to rhs. Characters other than digits following a '\#' character also represent the function key named by the characters in the lhs following the ' \#' and may be mapped to \(r\) hs. It is unspecified how function keys are named or what function keys are supported.

For text input mode mappings:
When the lhs is entered as any part of text entered in open or visual text input modes, the action shall be as if the corresponding rhs had been entered.

If any character in the input text is escaped using a <control>-V character, that character shall not be part of a match to an lhs.

It is unspecified whether the lhs text entered for subsequent map or unmap commands is replaced with the rhs text for the purposes of the screen display; regardless of whether or not the display appears as if the corresponding rhs text was entered, the effect of the command shall be as if the lhs text was entered.

If only part of the Ths is entered, it is unspecified how long the editor will wait for additional, possibly matching characters before treating the already entered characters as not matching the lhs.

The rhs characters shall themselves be subject to remapping, unless otherwise specified by the remap edit option, except that if the characters in lhs occur as prefix characters in rhs, those characters shall not be remapped.
On block-mode terminals, the mapping need not occur immediately (for example, it may occur after the terminal transmits a group of characters to the system), but it shall achieve the same results as if it occurred immediately.
Current line: Unchanged.
Current column: Unchanged.
Mark
Synopsis: [laddr] ma[rk] character
[laddr] k character
Implementations shall support character values of a single lowercase letter of the POSIX locale and the characters ' ' and \({ }^{\prime \prime}\) ' ; support of other characters is implementation-defined.
If executing the \(v i \mathbf{m}\) command, set the specified mark to the current line and 1-based numbered character referenced by the current column, if any; otherwise, column position 1.
Otherwise, set the specified mark to the specified line and 1-based numbered first non-<blank> non-<newline> in the line, if any; otherwise, the last non-<newline> in the line, if any; otherwise, column position 1 .
The mark shall remain associated with the line until the mark is reset or the line is deleted. If a
deleted line is restored by a subsequent undo command, any marks previously associated with the line, which have not been reset, shall be restored as well. Any use of a mark not associated with a current line in the edit buffer shall be an error.

The marks ' and ' shall be set as described previously, immediately before the following events occur in the editor:
1. The use of ' \(\$\) ' as an ex address
2. The use of a positive decimal number as an ex address
3. The use of a search command as an \(e x\) address
4. The use of a mark reference as an \(e x\) address
5. The use of the following open and visual mode commands: <control>-], \%, (, ), [, ], \{, \}
6. The use of the following open and visual mode commands: ' \(, \mathbf{G}, \mathbf{H}, \mathbf{L}, \mathbf{M}, \mathbf{z}\) if the current line will change as a result of the command
7. The use of the open and visual mode commands: /, ?, \(\mathbf{N},{ }^{\prime}, \mathbf{n}\) if the current line or column will change as a result of the command
8. The use of the ex mode commands: \(\mathbf{z}\), undo, global, \(\mathbf{v}\)

For rules 1., 2., 3., and 4., the ' and ' marks shall not be set if the ex command is parsed as specified by rule 6.a. in Command Line Parsing in ex (on page 364).

For rules 5., 6., and 7., the ' and ' marks shall not be set if the commands are used as motion commands in open and visual mode.
For rules 1., 2., 3., 4., 5., 6., 7., and 8., the ' and 'marks shall not be set if the command fails.
The ' and ' marks shall be set as described previously, each time the contents of the edit buffer are replaced (including the editing of the initial buffer), if in open or visual mode, or if in ex mode and the edit buffer is not empty, before any commands or movements (including commands or movements specified by the - \(\mathbf{c}\) or \(-\mathbf{t}\) options or the + command argument) are executed on the edit buffer. If in open or visual mode, the marks shall be set as if executing the vi \(\mathbf{m}\) command; otherwise, as if executing the ex mark command.

When changing from ex mode to open or visual mode, if the ' and ' marks are not already set, the ' and 'marks shall be set as described previously.

Current line: Unchanged.
Current column: Unchanged.

\section*{Move}

Synopsis: [2addr] m[ove] laddr [flags]
Move the specified lines after the specified destination line. A destination of line zero specifies that the lines shall be placed at the beginning of the edit buffer. It shall be an error if the destination line is within the range of lines to be moved.

Current line: Set to the last of the moved lines.
Current column: Set to non-<blank>.

\section*{Next}
```

Synopsis: n [ext][!][+Command][file ...]
If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the autowrite option.
If one or more files is specified:

1. Set the argument list to the specified filenames.
2. Set the current argument list reference to be the first entry in the argument list.
3. Set the current pathname to the first filename specified.
Otherwise:
4. It shall be an error if there are no more filenames in the argument list after the filename currently referenced.
5. Set the current pathname and the current argument list reference to the filename after the filename currently referenced in the argument list.
Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.
This command shall be affected by the autowrite and writeany edit options.
The +command option shall be <blank>-delimited; <blank>s can be escaped by preceding them with a backslash character. The +command shall be interpreted as an ex command immediately after the contents of the edit buffer have been replaced and the current line and column have been set.
Current line: Set as described for the edit command.
Current column: Set as described for the edit command.
```

\section*{Number}
```

Synopsis: [2addr] nu[mber][count][flags] [2addr] \#[count][flags]
These commands shall be equivalent to the ex command:
[2addr] p[rint][count] \#[flags]
See Print (on page 381).

```

\section*{Open}
```

Synopsis: [laddr] o[pen] /pattern/ [flags]
This command need not be supported on block-mode terminals or terminals with insufficient capabilities. If standard input, standard output, or standard error are not terminal devices, the results are unspecified.
Enter open mode.
The trailing delimiter can be omitted from pattern at the end of the command line. If pattern is empty (for example, "//") or not specified, the last regular expression used in the editor shall be used as the pattern. The pattern can be delimited by slashes (shown in the Synopsis), as well as any alphanumeric, or non-<blank> other than backslash, vertical line, double quote, or <newline>.

```

Current line: Set to the specified line.
Current column: Set to non-<blank>.

\section*{Preserve}

Synopsis: pre[serve]
Save the edit buffer in a form that can later be recovered by using the -r option or by using the ex recover command. After the file has been preserved, a mail message shall be sent to the user. This message shall be readable by invoking the mailx utility. The message shall contain the name of the file, the time of preservation, and an ex command that could be used to recover the file. Additional information may be included in the mail message.
Current line: Unchanged.
Current column: Unchanged.

\section*{Print}

Synopsis: [2addr] p[rint][count][flags]
Write the addressed lines. The behavior is unspecified if the number of columns on the display is less than the number of columns required to write any single character in the lines being written.
Non-printable characters, except for the <tab>, shall be written as implementation-defined multi-character sequences.
If the \# flag is specified or the number edit option is set, each line shall be preceded by its line number in the following format:
"\%6d \(\Delta \Delta "\) ", <line number>
If the \(\mathbf{1}\) flag is specified or the list edit option is set:
1. The characters listed in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions shall be written as the corresponding escape sequence.
2. Non-printable characters not in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first).
3. The end of each line shall be marked with a ' \(\$\) ', and literal \({ }^{\prime} \$ \prime\) characters within the line shall be written with a preceding backslash.
Long lines shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output terminal, considering the number of columns of the terminal.
If a line is folded, and the 1 flag is not specified and the list edit option is not set, it is unspecified whether a multi-column character at the folding position is separated; it shall not be discarded.
Current line: Set to the last written line.
Current column: Unchanged if the current line is unchanged; otherwise, set to non-<blank>.

Put
Synopsis: [1addr] pu[t][buffer]
Append text from the specified buffer (by default, the unnamed buffer) to the specified line; line zero specifies that the text shall be placed at the beginning of the edit buffer. Each portion of a line in the buffer shall become a new line in the edit buffer, regardless of the mode of the buffer.

Current line: Set to the last line entered into the edit buffer.
Current column: Set to non-<blank>.

\section*{Quit}

Synopsis: \(\quad\) [uit][!]
If no ' \(!\) ' is appended to the command name:
1. If the edit buffer has been modified since the last complete write, it shall be an error.
2. If there are filenames in the argument list after the filename currently referenced, and the last command was not a quit, wq, xit, or ZZ (see Exit (on page 1026)) command, it shall be an error.

Otherwise, terminate the editing session.

\section*{Read}

Synopsis: [1addr] r[ead][!][file]
If ' !' is not the first non-<blank> to follow the command name, a copy of the specified file shall be appended into the edit buffer after the specified line; line zero specifies that the copy shall be placed at the beginning of the edit buffer. The number of lines and bytes read shall be written. If no file is named, the current pathname shall be the default. If there is no current pathname, then file shall become the current pathname. If there is no current pathname or file operand, it shall be an error. Specifying a file that is not of type regular shall have unspecified results.

Otherwise, if file is preceded by ' ! ' , the rest of the line after the ' !' shall have \({ }^{\prime} \%\) ', ' \#', and '!' characters expanded as described in Command Line Parsing in ex (on page 364).

The ex utility shall then pass two arguments to the program named by the shell edit option; the first shall be -c and the second shall be the expanded arguments to the read command as a single argument. The standard input of the program shall be set to the standard input of the ex program when it was invoked. The standard error and standard output of the program shall be appended into the edit buffer after the specified line.
Each line in the copied file or program output (as delimited by <newline>s or the end of the file or output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline>s.

The special meaning of the '!' following the read command can be overridden by escaping it with a backslash character.

Current line: If no lines are added to the edit buffer, unchanged. Otherwise, if in open or visual mode, set to the first line entered into the edit buffer. Otherwise, set to the last line entered into the edit buffer.

Current column: Set to non-<blank>.

Recover
Synopsis: rec[over][!] file
If no '!' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error.
If no file operand is specified, then the current pathname shall be used. If there is no current pathname or file operand, it shall be an error.
If no recovery information has previously been saved about file, the recover command shall behave identically to the edit command, and an informational message to this effect shall be written.
Otherwise, set the current pathname to file, and replace the current contents of the edit buffer with the recovered contents of file. If there are multiple instances of the file to be recovered, the one most recently saved shall be recovered, and an informational message that there are previous versions of the file that can be recovered shall be written. The editor shall behave as if the contents of the edit buffer have already been modified.
Current file: Set as described for the edit command.
Current column: Set as described for the edit command.

\section*{Rewind}

Synopsis: rew[ind][!]
If no ' !' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the autowrite option.
If the argument list is empty, it shall be an error.
The current argument list reference and the current pathname shall be set to the first filename in the argument list.
Replace the contents of the edit buffer with the contents of the file named by the current pathname. If for any reason the contents of the file cannot be accessed, the edit buffer shall be empty.
This command shall be affected by the autowrite and writeany edit options.
Current line: Set as described for the edit command.
Current column: Set as described for the edit command.
Set
Synopsis: se[t][option[=[value]] ...][nooption ...][option? ...][all]
When no arguments are specified, write the value of the term edit option and those options whose values have been changed from the default settings; when the argument all is specified, write all of the option values.
Giving an option name followed by the character ' ?' shall cause the current value of that option to be written. The ' ?' can be separated from the option name by zero or more <blank>s. The '?' shall be necessary only for Boolean valued options. Boolean options can be given values by the form set option to turn them on or set nooption to turn them off; string and numeric options can be assigned by the form set option=value. Any <blank>s in strings can be included as is by preceding each <blank> with an escaping backslash. More than one option can be set or listed by a single set command by specifying multiple arguments, each separated from the next by one or more <blank>s.

\begin{abstract}
See Edit Options in ex for details about specific options.
Current line: Unchanged.
Current column: Unchanged.

\section*{Shell}

Synopsis: \(\quad \mathrm{sh}[\mathrm{ell}]\)
Invoke the program named in the shell edit option with the single argument \(-\mathbf{i}\) (interactive mode). Editing shall be resumed when the program exits.
Current line: Unchanged.
Current column: Unchanged.

\section*{Source}

Synopsis: so[urce] file
Read and execute ex commands from file. Lines in the file that are blank lines shall be ignored.
Current line: As specified for the individual ex commands.
Current column: As specified for the individual ex commands.

\section*{Substitute}

Synopsis: [2addr] s[ubstitute][/pattern/repl/[options][count][flags]]
[2addr] \&[options][count][flags]]
[2addr] ~[options][count][flags]]
Replace the first instance of the pattern pattern by the string repl on each specified line. (See Regular Expressions in ex and Replacement Strings in ex (on page 392).) Any non-alphabetic, non-<blank> delimiter other than ' \(\backslash \prime\) ' \(\gamma\) ', double quote, or <newline> can be used instead of '/'. Backslash characters can be used to escape delimiters, backslash characters, and other special characters.
The trailing delimiter can be omitted from pattern or from repl at the end of the command line. If both pattern and repl are not specified or are empty (for example, "//"), the last s command shall be repeated. If only pattern is not specified or is empty, the last regular expression used in the editor shall be used as the pattern. If only repl is not specified or is empty, the pattern shall be replaced by nothing. If the entire replacement pattern is \({ }^{\prime} \% \prime\), the last replacement pattern to an s command shall be used.
Entering a <carriage-return> in repl (which requires an escaping backslash in ex mode and an escaping <control>-V in open or vi mode) shall split the line at that point, creating a new line in the edit buffer. The <carriage-return> shall be discarded.
If options includes the letter ' g ' (global), all non-overlapping instances of the pattern in the line shall be replaced.

If options includes the letter ' \(c^{\prime}\) (confirm), then before each substitution the line shall be written; the written line shall reflect all previous substitutions. On the following line, <space>s shall be written beneath the characters from the line that are before the pattern to be replaced, and " \({ }^{\prime \prime}\) characters written beneath the characters included in the pattern to be replaced. The ex utility shall then wait for a response from the user. An affirmative response shall cause the substitution to be done, while any other input shall not make the substitution. An affirmative response shall consist of a line with the affirmative response (as defined by the current locale) at the beginning of the line. This line shall be subject to editing in the same way as the ex command line.
\end{abstract}

If interrupted (see the ASYNCHRONOUS EVENTS section), any modifications confirmed by the
user shall be preserved in the edit buffer after the interrupt.
If the remembered search direction is not set, the \(\boldsymbol{s}\) command shall set it to forward.
In the second Synopsis, the \& command shall repeat the previous substitution, as if the \& command were replaced by:
s/pattern/repl/
where pattern and repl are as specified in the previous \(\mathbf{s}, \&\), or \(\sim\) command.
In the third Synopsis, the \(\sim\) command shall repeat the previous substitution, as if the \({ }^{\prime \sim}{ }^{\prime}\) were replaced by:
s/pattern/repl/
where pattern shall be the last regular expression specified to the editor, and repl shall be from the previous substitution (including \& and \({ }^{\sim}\) ) command.
These commands shall be affected by the LC_MESSAGES environment variable.
Current line: Set to the last line in which a substitution occurred, or, unchanged if no substitution occurred.

Current column: Set to non-<blank>.
Suspend
Synopsis: \(\quad\) su[spend] [!]
st [op] [!]
Allow control to return to the invoking process; ex shall suspend itself as if it had received the SIGTSTP signal. The suspension shall occur only if job control is enabled in the invoking shell (see the description of set -m ).
These commands shall be affected by the autowrite and writeany edit options.
The current susp character (see stty) shall be equivalent to the suspend command.
Tag
Synopsis: ta[g][!] tagstring
The results are unspecified if the format of a tags file is not as specified by the ctags utility (see ctags) description.
The tag command shall search for tagstring in the tag files referred to by the tag edit option, in the order they are specified, until a reference to tagstring is found. Files shall be searched from beginning to end. If no reference is found, it shall be an error and an error message to this effect shall be written. If the reference is not found, or if an error occurs while processing a file referred to in the tag edit option, it shall be an error, and an error message shall be written at the first occurrence of such an error.

Otherwise, if the tags file contained a pattern, the pattern shall be treated as a regular expression used in the editor; for example, for the purposes of the s command.
If the tagstring is in a file with a different name than the current pathname, set the current pathname to the name of that file, and replace the contents of the edit buffer with the contents of that file. In this case, if no ' !' is appended to the command name, and the edit buffer has been modified since the last complete write, it shall be an error, unless the file is successfully written as specified by the autowrite option.
This command shall be affected by the autowrite, tag, taglength, and writeany edit options.
Current line: If the tags file contained a line number, set to that line number. If the line number is
larger than the last line in the edit buffer, an error message shall be written and the current line shall be set as specified for the edit command.
If the tags file contained a pattern, set to the first occurrence of the pattern in the file. If no matching pattern is found, an error message shall be written and the current line shall be set as specified for the edit command.

Current column: If the tags file contained a line-number reference and that line-number was not larger than the last line in the edit buffer, or if the tags file contained a pattern and that pattern was found, set to non-<blank>. Otherwise, set as specified for the edit command.

\section*{Unabbreviate}

Synopsis: una[bbrev] Ihs
If \(l h s\) is not an entry in the current list of abbreviations (see Abbreviate (on page 372)), it shall be an error. Otherwise, delete lhs from the list of abbreviations.

Current line: Unchanged.
Current column: Unchanged.

\section*{Undo}

Synopsis: u[ndo]
Reverse the changes made by the last command that modified the contents of the edit buffer, including undo. For this purpose, the global, \(\mathbf{v}\), open, and visual commands, and commands resulting from buffer executions and mapped character expansions, are considered single commands.

If no action that can be undone preceded the undo command, it shall be an error.
If the undo command restores lines that were marked, the mark shall also be restored unless it was reset subsequent to the deletion of the lines.

\section*{Current line:}
1. If lines are added or changed in the file, set to the first line added or changed.
2. Set to the line before the first line deleted, if it exists.
3. Set to 1 if the edit buffer is not empty.
4. Set to zero.

Current column: Set to non-<blank>.

\section*{Unmap}

Synopsis: unm[ap][!] Ihs
If '!' is appended to the command name, and if lhs is not an entry in the list of text input mode map definitions, it shall be an error. Otherwise, delete lhs from the list of text input mode map definitions.

If no '!' is appended to the command name, and if lhs is not an entry in the list of command mode map definitions, it shall be an error. Otherwise, delete lhs from the list of command mode map definitions.
Current line: Unchanged.
Current column: Unchanged.

Version
Synopsis: ve[rsion]
Write a message containing version information for the editor. The format of the message is unspecified.
Current line: Unchanged.
Current column: Unchanged.
Visual
Synopsis: [1addr] vi[sual][type][count][flags]
If \(e x\) is currently in open or visual mode, the Synopsis and behavior of the visual command shall be the same as the edit command, as specified by Edit (on page 374).
Otherwise, this command need not be supported on block-mode terminals or terminals with insufficient capabilities. If standard input, standard output, or standard error are not terminal devices, the results are unspecified.
If count is specified, the value of the window edit option shall be set to count (as described in window (on page 399)). If the ' ^' type character was also specified, the window edit option shall be set before being used by the type character.
Enter visual mode. If type is not specified, it shall be as if a type of '+' was specified. The type shall cause the following effects:
+ Place the beginning of the specified line at the top of the display.
- Place the end of the specified line at the bottom of the display.
- Place the beginning of the specified line in the midale of the display.
- If the specified line is less than or equal to the value of the window edit option, set the line to 1; otherwise, decrement the line by the value of the window edit option minus 1. Place the beginning of this line as close to the bottom of the displayed lines as possible, while still displaying the value of the window edit option number of lines.
Current line: Set to the specified line.
Current column: Set to non-<blank>.
Write
Synopsis:
[2addr] w[rite][!][>>][file]
[2addr] w[rite][!][file]
[2addr] wq[!][>>][file]
If no lines are specified, the lines shall default to the entire file.
The command \(\mathbf{w q}\) shall be equivalent to a write command followed by a quit command; wq! shall be equivalent to write! followed by quit. In both cases, if the write command fails, the quit shall not be attempted.
If the command name is not followed by one or more <blank>s, or file is not preceded by a '!' character, the write shall be to a file.
1. If the >> argument is specified, and the file already exists, the lines shall be appended to the file instead of replacing its contents. If the >> argument is specified, and the file does not already exist, it is unspecified whether the write shall proceed as if the >> argument had not been specified or if the write shall fail.
2. If the readonly edit option is set (see readonly (on page 396)), the write shall fail.
3. If file is specified, and is not the current pathname, and the file exists, the write shall fail.
4. If file is not specified, the current pathname shall be used. If there is no current pathname, the write command shall fail.
5. If the current pathname is used, and the current pathname has been changed by the file or read commands, and the file exists, the write shall fail. If the write is successful, subsequent writes shall not fail for this reason (unless the current pathname is changed again).
6. If the whole edit buffer is not being written, and the file to be written exists, the write shall fail.

For rules 1., 2., 4., and 5., the write can be forced by appending the character '!' to the command name.
For rules \(2 ., 4\). , and 5. , the write can be forced by setting the writeany edit option.
Additional, implementation-defined tests may cause the write to fail.
If the edit buffer is empty, a file without any contents shall be written.
An informational message shall be written noting the number of lines and bytes written.
Otherwise, if the command is followed by one or more <blank>s, and the file is preceded by '!', the rest of the line after the '!' shall have '\%', '\#' and '!' characters expanded as described in Command Line Parsing in ex (on page 364).
The \(e x\) utility shall then pass two arguments to the program named by the shell edit option; the first shall be -c and the second shall be the expanded arguments to the write command as a single argument. The specified lines shall be written to the standard input of the command. The standard error and standard output of the program, if any, shall be written as described for the print command. If the last character in that output is not a <newline>, a <newline> shall be written at the end of the output.
The special meaning of the ! ! following the write command can be overridden by escaping it with a backslash character.
Current line: Unchanged.
Current column: Unchanged.
Write and Exit
Synopsis: [2addr] \(\times\) [it][!][file]
If the edit buffer has not been modified since the last complete write, xit shall be equivalent to the quit command, or if a '!' is appended to the command name, to quit!.
Otherwise, xit shall be equivalent to the \(\mathbf{w q}\) command, or if a '!' is appended to the command name, to wq!.
Current line: Unchanged.
Current column: Unchanged.

Yank
Synopsis: [2addr] ya[nk][buffer][count]
Copy the specified lines to the specified buffer (by default, the unnamed buffer), which shall become a line-mode buffer.

Current line: Unchanged.
Current column: Unchanged.

\section*{Adjust Window}

Synopsis: [laddr] z[!][type ...][count][flags]
If no line is specified, the current line shall be the default; if type is omitted as well, the current line value shall first be incremented by 1 . If incrementing the current line would cause it to be greater than the last line in the edit buffer, it shall be an error.
If there are <blank>s between the type argument and the preceding \(\mathbf{z}\) command name or optional '!' character, it shall be an error.

If count is specified, the value of the window edit option shall be set to count (as described in window (on page 399)). If count is omitted, it shall default to 2 times the value of the scroll edit option, or if! was specified, the number of lines in the display minus 1.
If type is omitted, then count lines starting with the specified line shall be written. Otherwise, count lines starting with the line specified by the type argument shall be written.
The type argument shall change the lines to be written. The possible values of type are as follows:
- The specified line shall be decremented by the following value:
```

(((number of '\'' characters) x count) -1)

```

If the calculation would result in a number less than 1 , it shall be an error. Write lines from the edit buffer, starting at the new value of line, until count lines or the last line in the edit buffer has been written.
\(+\quad\) The specified line shall be incremented by the following value:
```

(((number of ''+'( characters) -1) x count) +1

```

If the calculation would result in a number greater than the last line in the edit buffer, it shall be an error. Write lines from the edit buffer, starting at the new value of line, until count lines or the last line in the edit buffer has been written.
\(=\), . If more than a single.\(^{\prime}\) or \({ }^{\prime}=\) is specified, it shall be an error. The following steps shall be taken:
1. If count is zero, nothing shall be written.
2. Write as many of the \(N\) lines before the current line in the edit buffer as exist. If count or ' !' was specified, \(N\) shall be:
```

(count -1) /2

```

Otherwise, \(N\) shall be:
```

(count -3) /2

```

If \(N\) is a number less than 3 , no lines shall be written.
3. If \({ }^{\prime}={ }^{\prime}\) was specified as the type character, write a line consisting of the smaller of the number of columns in the display divided by two, or \(40^{\prime} \mathbf{- '}^{\prime}\) characters.
4. Write the current line.
5. Repeat step 3.
6. Write as many of the \(N\) lines after the current line in the edit buffer as exist. \(N\) shall be defined as in step 2 . If \(N\) is a number less than 3 , no lines shall be written. If count is less than 3 , no lines shall be written.
- The specified line shall be decremented by the following value:
```

(((number of ```'' characters) +1) x count) -1

```

If the calculation would result in a number less than 1 , it shall be an error. Write lines from the edit buffer, starting at the new value of line, until count lines or the last line in the edit buffer has been written.

Current line: Set to the last line written, unless the type is \(=\), in which case, set to the specified line.

Current column: Set to non-<blank>.

\section*{Escape}

Synopsis: ! command
[addr]! command
The contents of the line after the '!' shall have '\%', ' \#', and '!' characters expanded as described in Command Line Parsing in ex (on page 364). If the expansion causes the text of the line to change, it shall be redisplayed, preceded by a single '!' character.
The \(e x\) utility shall execute the program named by the shell edit option. It shall pass two arguments to the program; the first shall be \(-\mathbf{c}\), and the second shall be the expanded arguments to the! command as a single argument.
If no lines are specified, the standard input, standard output, and standard error of the program shall be set to the standard input, standard output, and standard error of the ex program when it was invoked. In addition, a warning message shall be written if the edit buffer has been modified since the last complete write, and the warn edit option is set.

If lines are specified, they shall be passed to the program as standard input, and the standard output and standard error of the program shall replace those lines in the edit buffer. Each line in the program output (as delimited by <newline>s or the end of the output if it is not immediately preceded by a <newline>), shall be a separate line in the edit buffer. Any occurrences of <carriage-return> and <newline> pairs in the output shall be treated as single <newline>s. The specified lines shall be copied into the unnamed buffer before they are replaced, and the unnamed buffer shall become a line-mode buffer.

If in ex mode, a single ' ' character shall be written when the program completes.
This command shall be affected by the shell and warn edit options. If no lines are specified, this command shall be affected by the autowrite and writeany edit options. If lines are specified, this command shall be affected by the autoprint edit option.

\section*{Current line:}
1. If no lines are specified, unchanged.
2. Otherwise, set to the last line read in, if any lines are read in.
3. Otherwise, set to the line before the first line of the lines specified, if that line exists.
4. Otherwise, set to the first line of the edit buffer if the edit buffer is not empty.
5. Otherwise, set to zero.

Current column: If no lines are specified, unchanged. Otherwise, set to non-<blank>.

\section*{Shift Left}

Synopsis: [2addr] \(<\) [ \(<.].[\) count] [flags]
Shift the specified lines to the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the shiftwidth edit option. Only leading <blank>s shall be deleted or changed into other <blank>s in shifting; other characters shall not be affected.

Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the autoprint edit option.
Current line: Set to the last line in the lines specified.
Current column: Set to non-<blank>.

\section*{Shift Right}

Synopsis: [2addr] >[> ...][count][flags]
Shift the specified lines away from the start of the line; the number of column positions to be shifted shall be the number of command characters times the value of the shiftwidth edit option. The shift shall be accomplished by adding <blank>s as a prefix to the line or changing leading <blank>s into other <blank>s. Empty lines shall not be changed.
Lines to be shifted shall be copied into the unnamed buffer, which shall become a line-mode buffer.

This command shall be affected by the autoprint edit option.
Current line: Set to the last line in the lines specified.
Current column: Set to non-<blank>.
<control>-D
Synopsis: <control>-D
Write the next \(n\) lines, where \(n\) is the minimum of the values of the scroll edit option and the number of lines after the current line in the edit buffer. If the current line is the last line of the edit buffer it shall be an error.
Current line: Set to the last line written.
Current column: Set to non-<blank>.

\section*{Write Line Number}
\[
\text { Synopsis: } \quad[1 \mathrm{addr}]=[\text { flags }]
\]

If line is not specified, it shall default to the last line in the edit buffer. Write the line number of the specified line.
Current line: Unchanged.
Current column: Unchanged.

\section*{Execute}

Synopsis: [2addr] @ buffer [2addr] * buffer

If no buffer is specified or is specified as \({ }^{\prime} @^{\prime}\) or \(\boldsymbol{\prime}^{\star \prime \prime}\), the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

For each line specified by the addresses, set the current line ('.') to the specified line, and execute the contents of the named buffer (as they were at the time the @ command was executed) as ex commands. For each line of a line-mode buffer, and all but the last line of a character-mode buffer, the ex command parser shall behave as if the line was terminated by a <newline>.

If an error occurs during this process, or a line specified by the addresses does not exist when the current line would be set to it, or more than a single line was specified by the addresses, and the contents of the edit buffer are replaced (for example, by the ex :edit command) an error message shall be written, and no more commands resulting from the execution of this command shall be processed.
Current line: As specified for the individual ex commands.
Current column: As specified for the individual ex commands.

\section*{Regular Expressions in ex}

The ex utility shall support regular expressions that are a superset of the basic regular expressions described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. A null regular expression ("//") shall be equivalent to the last regular expression encountered.
Regular expressions can be used in addresses to specify lines and, in some commands (for example, the substitute command), to specify portions of a line to be substituted.
The following constructs can be used to enhance the basic regular expressions:
\(\backslash<\) Match the beginning of a word. (See the definition of word at the beginning of Command Descriptions in ex (on page 370).)
\> Match the end of a word.
~ Match the replacement part of the last substitute command. The tilde ( \({ }^{\prime} \sim \prime\) ) character can be escaped in a regular expression to become a normal character with no special meaning. The backslash shall be discarded.
When the editor option magic is not set, the only characters with special meanings shall be \(\quad\) ^r at the beginning of a pattern, ' \(\$^{\prime}\) at the end of a pattern, and ' \(\backslash\) '. The characters ' \({ }^{\prime} \prime^{\prime},{ }^{\prime \prime}\) ', ' [', and ' \(\sim\) ' shall be treated as ordinary characters unless preceded by a ' \(\backslash\) '; when preceded by a ' \(\backslash\) ' they shall regain their special meaning, or in the case of backslash, be handled as a single backslash. Backslashes used to escape other characters shall be discarded.

\section*{Replacement Strings in ex}

The character \({ }^{\prime}{ }^{\prime}{ }^{\prime}\left({ }^{\prime} \backslash{ }^{\prime}{ }^{\prime}\right.\) if the editor option magic is not set) in the replacement string shall stand for the text matched by the pattern to be replaced. The character \(\boldsymbol{\prime}^{\prime \prime}(\prime \backslash \sim\) ' if magic is not set) shall be replaced by the replacement part of the previous substitute command. The sequence ' \(\backslash \mathrm{n}\) ', where \(n\) is an integer, shall be replaced by the text matched by the corresponding back-reference expression. If the corresponding back-reference expression does not match, then the characters ' \(\backslash \mathrm{n}\) ' shall be replaced by the empty string.
The strings ' \(\backslash 1^{\prime} \prime^{\prime} \backslash \mathbf{u}^{\prime},^{\prime} \backslash \mathrm{L}^{\prime}\), and \({ }^{\prime} \backslash \mathrm{U}^{\prime}\) can be used to modify the case of elements in the replacement string (using the \({ }^{\prime} \backslash \varepsilon^{\prime}\) ' or " \(\backslash\) "digit) notation. The string \({ }^{\prime} \backslash l^{\prime}\left({ }^{\prime} \backslash u^{\prime}\right)\) shall cause the character that follows to be converted to lowercase (uppercase). The string ' \(\backslash \mathrm{L}^{\prime}{ }^{\prime}\left({ }^{\prime} \backslash \mathrm{U}^{\prime}\right)\) shall
cause all characters subsequent to it to be converted to lowercase (uppercase) as they are inserted by the substitution until the string ' \(\backslash e^{\prime}\) or ' \(\backslash E^{\prime}\), or the end of the replacement string, is encountered.
Otherwise, any character following a backslash shall be treated as that literal character, and the escaping backslash shall be discarded.

An example of case conversion with the \(\mathbf{s}\) command is as follows:
: p
The cat sat on the mat.
:s/\<.at\>/\u\&/gp
The Cat Sat on the Mat.
:s/S\\(.*\\)M/S\U\1\eM/p
The Cat SAt ON the Mat.

\section*{Edit Options in ex}

The ex utility has a number of options that modify its behavior. These options have default settings, which can be changed using the set command.

Options are Boolean unless otherwise specified.
autoindent, ai
[Default unset]
If autoindent is set, each line in input mode shall be indented (using first as many <tab>s as possible, as determined by the editor option tabstop, and then using <space>s) to align with another line, as follows:
1. If in open or visual mode and the text input is part of a line-oriented command (see the EXTENDED DESCRIPTION in vi), align to the first column.
2. Otherwise, if in open or visual mode, indentation for each line shall be set as follows:
a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the <control>-D character in Input Mode Commands in vi (on page 1026).
b. Otherwise, it shall be set to the indentation of the previous current line, if any; otherwise, to the first column.
3. For the ex \(\mathbf{a}, \mathbf{i}\), and \(\mathbf{c}\) commands, indentation for each line shall be set as follows:
a. If a line was previously inserted as part of this command, it shall be set to the indentation of the last inserted line by default, or as otherwise specified for the eof character in Scroll (on page 368).
b. Otherwise, if the command is the ex a command, it shall be set to the line appended after, if any; otherwise to the first column.
c. Otherwise, if the command is the \(e x \mathbf{i}\) command, it shall be set to the line inserted before, if any; otherwise to the first column.
d. Otherwise, if the command is the exccommand, it shall be set to the indentation of the line replaced.
autoprint, ap
[Default set]
If autoprint is set, the current line shall be written after each ex command that modifies the contents of the current edit buffer, and after each tag command for which the tag search pattern was found or tag line number was valid, unless:
1. The command was executed while in open or visual mode.
2. The command was executed as part of a global or \(\mathbf{v}\) command or @ buffer execution.
3. The command was the form of the read command that reads a file into the edit buffer.
4. The command was the append, change, or insert command.
5. The command was not terminated by a <newline>.
6. The current line shall be written by a flag specified to the command; for example, delete \# shall write the current line as specified for the flag modifier to the delete command, and not as specified by the autoprint edit option.

\section*{autowrite, aw}
[Default unset]
If autowrite is set, and the edit buffer has been modified since it was last completely written to any file, the contents of the edit buffer shall be written as if the ex write command had been specified without arguments, before each command affected by the autowrite edit option is executed. Appending the character '!' to the command name of any of the ex commands except '!' shall prevent the write. If the write fails, it shall be an error and the command shall not be executed.

\section*{beautify, bf}
[Default unset]
If beautify is set, all non-printable characters, other than <tab>s, <newline>s, and <form-feed>s, shall be discarded from text read in from files.

\section*{directory, dir}
[Default implementation-defined]
The value of this option specifies the directory in which the editor buffer is to be placed. If this directory is not writable by the user, the editor shall quit.
edcompatible, ed
[Default unset]
Causes the presence of \(\mathbf{g}\) and \(\mathbf{c}\) suffixes on substitute commands to be remembered, and toggled by repeating the suffixes.
errorbells, eb
[Default unset]
If the editor is in \(e x\) mode, and the terminal does not support a standout mode (such as inverse video), and errorbells is set, error messages shall be preceded by alerting the terminal.
exrc
[Default unset]
If exrc is set, \(e x\) shall access any .exrc file in the current directory, as described in Initialization in ex and vi (on page 360). If exrc is not set, ex shall ignore any .exrc file in the current directory during initialization, unless the current directory is that named by the HOME environment variable.
ignorecase, ic
[Default unset]
If ignorecase is set, characters that have uppercase and lowercase representations shall have those representations considered as equivalent for purposes of regular expression comparison.

The ignorecase edit option shall affect all remembered regular expressions; for example, unsetting the ignorecase edit option shall cause a subsequent vi \(\mathbf{n}\) command to search for the last basic regular expression in a case-sensitive fashion.

\section*{list}
[Default unset]
If list is set, edit buffer lines written while in ex command mode shall be written as specified for the print command with the 1 flag specified. In open or visual mode, each edit buffer line shall be displayed as specified for the ex print command with the 1 flag specified. In open or visual text input mode, when the cursor does not rest on any character in the line, it shall rest on the ' \$' marking the end of the line.

\section*{magic}
[Default set]
If magic is set, modify the interpretation of characters in regular expressions and substitution replacement strings (see Regular Expressions in ex and Replacement Strings in ex (on page 392)).
mesg
[Default set]
If mesg is set, the permission for others to use the write or talk commands to write to the terminal shall be turned on while in open or visual mode. The shell-level command mesg \(\mathbf{n}\) shall take precedence over any setting of the ex mesg option; that is, if mesg \(y\) was issued before the editor started (or in a shell escape), such as:
```

:!mesg y

```
the mesg option in \(e x\) shall suppress incoming messages, but the mesg option shall not enable incoming messages if mesg \(\mathbf{n}\) was issued.

\section*{number, nu}
```

[Default unset]
If number is set, edit buffer lines written while in ex command mode shall be written with line numbers, in the format specified by the print command with the \# flag specified. In ex text input mode, each line shall be preceded by the line number it will have in the file.
In open or visual mode, each edit buffer line shall be displayed with a preceding line number, in the format specified by the ex print command with the \# flag specified. This line number shall not be considered part of the line for the purposes of evaluating the current column; that is, column position 1 shall be the first column position after the format specified by the print command.

```

\section*{paragraphs, para}
```

[Default in the POSIX locale IPLPPPQPP LIpplpipbp]
The paragraphs edit option shall define additional paragraph boundaries for the open and visual mode commands. The paragraphs edit option can be set to a character string consisting of zero or more character pairs. It shall be an error to set it to an odd number of characters.

```

\section*{prompt}
```

[Default set]
If prompt is set, ex command mode input shall be prompted for with a colon (' ${ }^{\prime}$ ); when unset, no prompt shall be written.
readonly
[Default see text]
If the readonly edit option is set, read-only mode shall be enabled (see Write (on page 387)). The readonly edit option shall be initialized to set if either of the following conditions are true:

- The command-line option -R was specified.
- Performing actions equivalent to the access() function called with the following arguments indicates that the file lacks write permission:

1. The current pathname is used as the path argument.
2. The constant $\mathbf{W}$ _OK is used as the amode argument.
The readonly edit option may be initialized to set for other, implementation-defined reasons. The readonly edit option shall not be initialized to unset based on any special privileges of the user or process. The readonly edit option shall be reinitialized each time that the contents of the edit buffer are replaced (for example, by an edit or next command) unless the user has explicitly set it, in which case it shall remain set until the user explicitly unsets it. Once unset, it shall again be reinitialized each time that the contents of the edit buffer are replaced.
```

\section*{redraw}
```

[Default unset]
The editor simulates an intelligent terminal on a dumb terminal. (Since this is likely to require a large amount of output to the terminal, it is useful only at high transmission speeds.)

```
remap
[Default set]
If remap is set, map translation shall allow for maps defined in terms of other maps; translation shall continue until a final product is obtained. If unset, only a one-step translation shall be done.

\section*{report}
[Default 5]
The value of this report edit option specifies what number of lines being added, copied, deleted, or modified in the edit buffer will cause an informational message to be written to the user. The following conditions shall cause an informational message. The message shall contain the number of lines added, copied, deleted, or modified, but is otherwise unspecified.
- An \(e x\) or \(v i\) editor command, other than open, undo, or visual, that modifies at least the value of the report edit option number of lines, and which is not part of an ex global or \(\mathbf{v}\) command, or \(e x\) or \(v i\) buffer execution, shall cause an informational message to be written.
- An ex yank or vi \(\mathbf{y}\) or \(\mathbf{Y}\) command, that copies at least the value of the report edit option plus 1 number of lines, and which is not part of an ex global or \(\mathbf{v}\) command, or ex or \(v i\) buffer execution, shall cause an informational message to be written.
- An ex global, \(\mathbf{v}\), open, undo, or visual command or ex or vi buffer execution, that adds or deletes a total of at least the value of the report edit option number of lines, and which is not part of an ex global or \(\mathbf{v}\) command, or ex or vi buffer execution, shall cause an informational message to be written. (For example, if 3 lines were added and 8 lines deleted during an ex visual command, 5 would be the number compared against the report edit option after the command completed.)
scroll, scr
[Default (number of lines in the display -1)/2]
The value of the scroll edit option shall determine the number of lines scrolled by the ex <control>-D and \(\mathbf{z}\) commands. For the \(v i\) <control>-D and <control>-U commands, it shall be the initial number of lines to scroll when no previous <control>-D or <control>-U command has been executed.

\section*{sections}
[Default in the POSIX locale NHSHH HUnhsh]
The sections edit option shall define additional section boundaries for the open and visual mode commands. The sections edit option can be set to a character string consisting of zero or more character pairs; it shall be an error to set it to an odd number of characters.
shell, sh
[Default from the environment variable SHELL]
The value of this option shall be a string. The default shall be taken from the SHELL environment variable. If the SHELL environment variable is null or empty, the sh (see sh) utility shall be the default.

\section*{shiftwidth, sw}
[Default 8]
The value of this option shall give the width in columns of an indentation level used during autoindentation and by the shift commands (< and >).

\section*{showmatch, sm}
[Default unset]
The functionality described for the showmatch edit option need not be supported on blockmode terminals or terminals with insufficient capabilities.

If showmatch is set, in open or visual mode, when a' \()^{\prime}\) or ' \}' is typed, if the matching ' (' or ' \(\{\) ' is currently visible on the display, the matching ' (' or ' \(\{\) ' shall be flagged moving the cursor to its location for an unspecified amount of time.

\section*{showmode}
[Default unset]
If showmode is set, in open or visual mode, the current mode that the editor is in shall be displayed on the last line of the display. Command mode and text input mode shall be differentiated; other unspecified modes and implementation-defined information may be displayed.

\section*{slowopen}
[Default unset]
If slowopen is set during open and visual text input modes, the editor shall not update portions of the display other than those display line columns that display the characters entered by the user (see Input Mode Commands in vi (on page 1026)).

\section*{tabstop, ts}
[Default 8]
The value of this edit option shall specify the column boundary used by a <tab> in the display (see autoprint, ap and Input Mode Commands in vi (on page 1026)).

\section*{taglength, tl}
[Default zero]
The value of this edit option shall specify the maximum number of characters that are considered significant in the user-specified tag name and in the tag name from the tags file. If the value is zero, all characters in both tag names shall be significant.

\section*{tags}

\section*{[Default see text]}

The value of this edit option shall be a string of <blank>-delimited pathnames of files used by the \(\boldsymbol{t a g}\) command. The default value is unspecified.

\section*{term}
[Default from the environment variable TERM]
The value of this edit option shall be a string. The default shall be taken from the TERM variable in the environment. If the TERM environment variable is empty or null, the default is unspecified. The editor shall use the value of this edit option to determine the type of the display device.

The results are unspecified if the user changes the value of the term edit option after editor initialization.

\section*{terse}
[Default unset]
If terse is set, error messages may be less verbose. However, except for this caveat, error messages are unspecified. Furthermore, not all error messages need change for different settings of this option.
warn
[Default set]
If warn is set, and the contents of the edit buffer have been modified since they were last completely written, the editor shall write a warning message before certain! commands (see Escape (on page 390)).

\section*{window}
[Default see text]
A value used in open and visual mode, by the <control>-B and <control>-F commands, and, in visual mode, to specify the number of lines displayed when the screen is repainted.
If the \(-\mathbf{w}\) command-line option is not specified, the default value shall be set to the value of the LINES environment variable. If the LINES environment variable is empty or null, the default shall be the number of lines in the display minus 1 .
Setting the window edit option to zero or to a value greater than the number of lines in the display minus 1 (either explicitly or based on the -w option or the LINES environment variable) shall cause the window edit option to be set to the number of lines in the display minus 1.
The baud rate of the terminal line may change the default in an implementation-defined manner.
wrapmargin, wm
[Default 0]
If the value of this edit option is zero, it shall have no effect.
If not in the POSIX locale, the effect of this edit option is implementation-defined.
Otherwise, it shall specify a number of columns from the ending margin of the terminal.
During open and visual text input modes, for each character for which any part of the character is displayed in a column that is less than wrapmargin columns from the ending margin of the display line, the editor shall behave as follows:
1. If the character triggering this event is a <blank>, it, and all immediately preceding <blank>s on the current line entered during the execution of the current text input command, shall be discarded, and the editor shall behave as if the user had entered a single <newline> instead. In addition, if the next user-entered character is a <space>, it
shall be discarded as well.
2. Otherwise, if there are one or more <blank>s on the current line immediately preceding the last group of inserted non-<blank>s which was entered during the execution of the current text input command, the <blank>s shall be replaced as if the user had entered a single <newline> instead.

If the autoindent edit option is set, and the events described in 1. or 2. are performed, any <blank>s at or after the cursor in the current line shall be discarded.

The ending margin shall be determined by the system or overridden by the user, as described for COLUMNS in the ENVIRONMENT VARIABLES section and the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

\section*{wrapscan, ws}
[Default set]
If wrapscan is set, searches (the ex / or ? addresses, or open and visual mode /, ?, \(\mathbf{N}\), and \(\mathbf{n}\) commands) shall wrap around the beginning or end of the edit buffer; when unset, searches shall stop at the beginning or end of the edit buffer.

\section*{writeany, wa}
[Default unset]
If writeany is set, some of the checks performed when executing the ex write commands shall be inhibited, as described in editor option autowrite.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

When any error is encountered and the standard input is not a terminal device file, ex shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered, it shall be equivalent to a SIGHUP asynchronous event.
Otherwise, when an error is encountered, the editor shall behave as specified in Command Line Parsing in ex (on page 364).

\section*{APPLICATION USAGE}

If a SIGSEGV signal is received while \(e x\) is saving a file, the file might not be successfully saved.
The next command can accept more than one file, so usage such as:
```

next 'ls [abc]*`

```
is valid; it would not be valid for the edit or read commands, for example, because they expect only one file and unspecified results occur.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The \(e x / v i\) specification is based on the historical practice found in the 4 BSD and System V implementations of \(e x\) and \(v i\).

A restricted editor (both the historical red utility and modifications to ex) were considered and rejected for inclusion. Neither option provided the level of security that users might expect.

It is recognized that ex visual mode and related features would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing; thus, it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that an ex implementation should provide the full set of capabilities on all terminals capable of supporting them.

\section*{Options}

The -c replacement for +command was inspired by the -e option of sed. Historically, all such commands (see edit and next as well) were executed from the last line of the edit buffer. This meant, for example, that "+/pattern" would fail unless the wrapscan option was set. IEEE Std 1003.1-200x requires conformance to historical practice. The +command option is no longer specified by this standard but may be present in some implementations. Historically, some implementations restricted the ex commands that could be listed as part of the command line arguments. For consistency, IEEE Std 1003.1-200x does not permit these restrictions.

In historical implementations of the editor, the \(-\mathbf{R}\) option (and the readonly edit option) only prevented overwriting of files; appending to files was still permitted, mapping loosely into the csh noclobber variable. Some implementations, however, have not followed this semantic, and readonly does not permit appending either. IEEE Std 1003.1-200x follows the latter practice, believing that it is a more obvious and intuitive meaning of readonly.
The -s option suppresses all interactive user feedback and is useful for editing scripts in batch jobs. The list of specific effects is historical practice. The terminal type "incapable of supporting open and visual modes" has historically been named "dumb".

The \(-\mathbf{t}\) option was required because the ctags utility appears in IEEE Std 1003.1-200x and the option is available in all historical implementations of ex.

Historically, the ex and vi utilities accepted a -x option, which did encryption based on the algorithm found in the historical crypt utility. The \(-\mathbf{x}\) option for encryption, and the associated crypt utility, were omitted because the algorithm used was not specifiable and the export control laws of some nations make it difficult to export cryptographic technology. In addition, it did not historically provide the level of security that users might expect.

\section*{Standard Input}

An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically an ex command.
There was no maximum line length in historical implementations of ex. Specifically, as it was parsed in chunks, the addresses had a different maximum length than the filenames. Further, the maximum line buffer size was declared as BUFSIZ, which was different lengths on different systems. This version selected the value of \{LINE_MAX\} to impose a reasonable restriction on portable usage of \(e x\) and to aid test suite writers in their development of realistic tests that exercise this limit.

\section*{Input Files}

It was an explicit decision by the standard developers that a <newline> be added to any file lacking one. It was believed that this feature of \(e x\) and \(v i\) was relied on by users in order to make text files lacking a trailing <newline> more portable. It is recognized that this will require a userspecified option or extension for implementations that permit \(e x\) and \(v i\) to edit files of type other than text if such files are not otherwise identified by the system. It was agreed that the ability to edit files of arbitrary type can be useful, but it was not considered necessary to mandate that an ex or vi implementation be required to handle files other than text files.

The paragraph in the INPUT FILES section, "By default, ...", is intended to close a longstanding security problem in ex and vi; that of the "modeline" or "modelines" edit option. This feature allows any line in the first or last five lines of the file containing the strings "ex: " or "vi:" (and, apparently, "ei:" or "vx:") to be a line containing editor commands, and ex interprets all the text up to the next ' \(:^{\prime}\) or <newline> as a command. Consider the consequences, for example, of an unsuspecting user using ex or \(v i\) as the editor when replying to a mail message in which a line such as:
ex: ! rm -rf :
appeared in the signature lines. The standard developers believed strongly that an editor should not by default interpret any lines of a file. Vendors are strongly urged to delete this feature from their implementations of \(e x\) and \(v i\).

\section*{Asynchronous Events}

The intention of the phrase "complete write" is that the entire edit buffer be written to stable storage. The note regarding temporary files is intended for implementations that use temporary files to back edit buffers unnamed by the user.
Historically, SIGQUIT was ignored by ex, but was the equivalent of the \(\mathbf{Q}\) command in visual mode; that is, it exited visual mode and entered ex mode. IEEE Std 1003.1-200x permits, but does not require, this behavior. Historically, SIGINT was often used by vi users to terminate text input mode (<control>-C is often easier to enter than \(<E S C>\) ). Some implementations of \(v i\) alerted the terminal on this event, and some did not. IEEE Std 1003.1-200x requires that SIGINT behave identically to \(<\mathrm{ESC}>\), and that the terminal not be alerted.
Historically, suspending the ex editor during text input mode was similar to SIGINT, as completed lines were retained, but any partial line discarded, and the editor returned to command mode. IEEE Std 1003.1-200x is silent on this issue; implementations are encouraged to follow historical practice, where possible.
Historically, the vi editor did not treat SIGTSTP as an asynchronous event, and it was therefore impossible to suspend the editor in visual text input mode. There are two major reasons for this. The first is that SIGTSTP is a broadcast signal on UNIX systems, and the chain of events where the shell execs an application that then execs vi usually caused confusion for the terminal state if SIGTSTP was delivered to the process group in the default manner. The second was that most implementations of the UNIX curses package are not reentrant, and the receipt of SIGTSTP at the wrong time will cause them to crash. IEEE Std 1003.1-200x is silent on this issue; implementations are encouraged to treat suspension as an asynchronous event if possible.

Historically, modifications to the edit buffer made before SIGINT interrupted an operation were retained; that is, anywhere from zero to all of the lines to be modified might have been modified by the time the SIGINT arrived. These changes were not discarded by the arrival of SIGINT. IEEE Std 1003.1-200x permits this behavior, noting that the undo command is required to be able to undo these partially completed commands.
The action taken for signals other than SIGINT, SIGCONT, SIGHUP, and SIGTERM is unspecified because some implementations attempt to save the edit buffer in a useful state when
other signals are received.

\section*{Standard Error}

For ex/vi, diagnostic messages are those messages reported as a result of a failed attempt to invoke ex or vi, such as invalid options or insufficient resources, or an abnormal termination condition. Diagnostic messages should not be confused with the error messages generated by inappropriate or illegal user commands.

\section*{Initialization in ex and vi}

If an ex command (other than cd, chdir, or source) has a filename argument, one or both of the alternate and current pathnames will be set. Informally, they are set as follows:
1. If the ex command is one that replaces the contents of the edit buffer, and it succeeds, the current pathname will be set to the filename argument (the first filename argument in the case of the next command) and the alternate pathname will be set to the previous current pathname, if there was one.
2. In the case of the file read/write forms of the read and write commands, if there is no current pathname, the current pathname will be set to the filename argument.
3. Otherwise, the alternate pathname will be set to the filename argument.

For example, :edit foo and :recover foo, when successful, set the current pathname, and, if there was a previous current pathname, the alternate pathname. The commands :write, !command, and :edit set neither the current or alternate pathnames. If the :edit foo command were to fail for some reason, the alternate pathname would be set. The read and write commands set the alternate pathname to their file argument, unless the current pathname is not set, in which case they set the current pathname to their file arguments. The alternate pathname was not historically set by the :source command. IEEE Std 1003.1-200x requires conformance to historical practice. Implementations adding commands that take filenames as arguments are encouraged to set the alternate pathname as described here.
Historically, ex and vi read the .exrc file in the \$HOME directory twice, if the editor was executed in the \(\$ H O M E\) directory. IEEE Std 1003.1-200x prohibits this behavior.

Historically, the 4 BSD \(e x\) and vi read the \(\$ H O M E\) and local .exrc files if they were owned by the real ID of the user, or the sourceany option was set, regardless of other considerations. This was a security problem because it is possible to put normal UNIX system commands inside a .exrc file. IEEE Std 1003.1-200x does not specify the sourceany option, and historical implementations are encouraged to delete it.
The .exrc files must be owned by the real ID of the user, and not writable by anyone other than the owner. The appropriate privileges exception is intended to permit users to acquire special privileges, but continue to use the .exrc files in their home directories.
System V Release 3.2 and later vi implementations added the option [no]exrc. The behavior is that local .exrc files are read-only if the exrc option is set. The default for the exrc option was off, so by default, local .exrc files were not read. The problem this was intended to solve was that System V permitted users to give away files, so there is no possible ownership or writeability test to ensure that the file is safe. This is still a security problem on systems where users can give away files, but there is nothing additional that IEEE Std 1003.1-200x can do. The implementation-defined exception is intended to permit groups to have local .exrc files that are shared by users, by creating pseudo-users to own the shared files.

IEEE Std 1003.1-200x does not mention system-wide \(e x\) and \(v i\) start-up files. While they exist in several implementations of \(e x\) and \(v i\), they are not present in any implementations considered historical practice by IEEE Std 1003.1-200x. Implementations that have such files should use them only if they are owned by the real user ID or an appropriate user (for example, root on

UNIX systems) and if they are not writable by any user other than their owner. System-wide start-up files should be read before the EXINIT variable, \$HOME/.exrc, or local .exrc files are evaluated.

Historically, any ex command could be entered in the EXINIT variable or the .exrc file, although ones requiring that the edit buffer already contain lines of text generally caused historical implementations of the editor to drop core. IEEE Std 1003.1-200x requires that any ex command be permitted in the EXINIT variable and .exrc files, for simplicity of specification and consistency, although many of them will obviously fail under many circumstances.
The initialization of the contents of the edit buffer uses the phrase "the effect shall be" with regard to various ex commands. The intent of this phrase is that edit buffer contents loaded during the initialization phase not be lost; that is, loading the edit buffer should fail if the .exrc file read in the contents of a file and did not subsequently write the edit buffer. An additional intent of this phrase is to specify that the initial current line and column is set as specified for the individual ex commands.

Historically, the -t option behaved as if the tag search were a +command; that is, it was executed from the last line of the file specified by the tag. This resulted in the search failing if the pattern was a forward search pattern and the wrapscan edit option was not set. IEEE Std 1003.1-200x does not permit this behavior, requiring that the search for the tag pattern be performed on the entire file, and, if not found, that the current line be set to a more reasonable location in the file.

Historically, the empty edit buffer presented for editing when a file was not specified by the user was unnamed. This is permitted by IEEE Std 1003.1-200x; however, implementations are encouraged to provide users a temporary filename for this buffer because it permits them the use of ex commands that use the current pathname during temporary edit sessions.
Historically, the file specified using the \(-\mathbf{t}\) option was not part of the current argument list. This practice is permitted by IEEE Std 1003.1-200x; however, implementations are encouraged to include its name in the current argument list for consistency.
Historically, the -c command was generally not executed until a file that already exists was edited. IEEE Std 1003.1-200x requires conformance to this historical practice. Commands that could cause the -c command to be executed include the ex commands edit, next, recover, rewind, and tag, and the vi commands <control>-^ and <control>-]. Historically, reading a file into an edit buffer did not cause the -c command to be executed (even though it might set the current pathname) with the exception that it did cause the -c command to be executed if: the editor was in ex mode, the edit buffer had no current pathname, the edit buffer was empty, and no read commands had yet been attempted. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.
Historically, the \(-r\) option was the same as a normal edit session if there was no recovery information available for the file. This allowed users to enter:
vi -r *.c
and recover whatever files were recoverable. In some implementations, recovery was attempted only on the first file named, and the file was not entered into the argument list; in others, recovery was attempted for each file named. In addition, some historical implementations ignored \(-\mathbf{r}\) if \(-\mathbf{t}\) was specified or did not support command line file arguments with the \(-\mathbf{t}\) option. For consistency and simplicity of specification, IEEE Std 1003.1-200x disallows these special cases, and requires that recovery be attempted the first time each file is edited.
Historically, vi initialized the ' and 'marks, but ex did not. This meant that if the first command in \(e x\) mode was visual or if an \(e x\) command was executed first (for example, vi+10 file), vi was entered without the marks being initialized. Because the standard developers believed the marks to be generally useful, and for consistency and simplicity of specification, IEEE Std 1003.1-200x requires that they always be initialized if in open or visual mode, or if in ex mode and the edit
buffer is not empty. Not initializing it in ex mode if the edit buffer is empty is historical practice; however, it has always been possible to set (and use) marks in empty edit buffers in open and visual mode edit sessions.

\section*{Addressing}

Historically, ex and vi accepted the additional addressing forms ' \(\backslash /{ }^{\prime}\) and \({ }^{\prime} \backslash ?^{\prime}\). They were equivalent to "//" and "??", respectively. They are not required by IEEE Std 1003.1-200x, mostly because nobody can remember whether they ever did anything different historically.
Historically, ex and vi permitted an address of zero for several commands, and permitted the \% address in empty files for others. For consistency, IEEE Std 1003.1-200x requires support for the former in the few commands where it makes sense, and disallows it otherwise. In addition, because IEEE Std 1003.1-200x requires that \% be logically equivalent to " \(1, \$\) ", it is also supported where it makes sense and disallowed otherwise.
Historically, the \% address could not be followed by further addresses. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that additional addresses be supported.
All of the following are valid addresses:
\(++\quad\) Three lines after the current line.
/re/- One line before the next occurrence of \(r\).
-2 Two lines before the current line.
3 ---- 2 Line one (note intermediate negative address).
123 Line six.
Any number of addresses can be provided to commands taking addresses; for example, " \(1,2,3,4,5\) p" prints lines 4 and 5 , because two is the greatest valid number of addresses accepted by the print command. This, in combination with the semicolon delimiter, permits users to create commands based on ordered patterns in the file. For example, the command 3;/foo/;+2print will display the first line after line 3 that contains the pattern foo, plus the next two lines. Note that the address 3; must be evaluated before being discarded because the search origin for the /foo/ command depends on this.
Historically, values could be added to addresses by including them after one or more <blank>s; for example, \(3-5 p\) wrote the seventh line of the file, and /foo/ 5 was the same as \(/ \mathrm{foo} /+5\). However, only absolute values could be added; for example, 5 /foo/ was an error. IEEE Std 1003.1-200x requires conformance to historical practice. Address offsets are separately specified from addresses because they could historically be provided to visual mode search commands.

Historically, any missing addresses defaulted to the current line. This was true for leading and trailing comma-delimited addresses, and for trailing semicolon-delimited addresses. For consistency, IEEE Std 1003.1-200x requires it for leading semicolon addresses as well.

Historically, ex and vi accepted the \({ }^{\prime \times \prime}\) character as both an address and as a flag offset for commands. In both cases it was identical to the \({ }^{\prime}{ }^{\prime}\) character. IEEE Std 1003.1-200x does not require or prohibit this behavior.
Historically, the enhancements to basic regular expressions could be used in addressing; for example, \(\quad \sim^{\prime}, \quad \backslash \ll^{\prime}\), and \(\quad \backslash>^{\prime}\). IEEE Std 1003.1-200x requires conformance to historical practice; that is, that regular expression usage be consistent, and that regular expression enhancements be supported wherever regular expressions are used.

\section*{Command Line Parsing in ex}

Historical ex command parsing was even more complex than that described here. IEEE Std 1003.1-200x requires the subset of the command parsing that the standard developers believed was documented and that users could reasonably be expected to use in a portable fashion, and that was historically consistent between implementations. (The discarded functionality is obscure, at best.) Historical implementations will require changes in order to comply with IEEE Std 1003.1-200x; however, users are not expected to notice any of these changes. Most of the complexity in ex parsing is to handle three special termination cases:
1. The !, global, \(\mathbf{v}\), and the filter versions of the read and write commands are delimited by <newline>s (they can contain vertical-line characters that are usually shell pipes).
2. The ex, edit, next, and visual in open and visual mode commands all take ex commands, optionally containing vertical-line characters, as their first arguments.
3. The \(\mathbf{s}\) command takes a regular expression as its first argument, and uses the delimiting characters to delimit the command.

Historically, vertical-line characters in the +command argument of the ex, edit, next, vi, and visual commands, and in the pattern and replacement parts of the s command, did not delimit the command, and in the filter cases for read and write, and the !, global, and \(\mathbf{v}\) commands, they did not delimit the command at all. For example, the following commands are all valid:
```

:edit +25 | s/abc/ABC/ file.c
:s/ | /PIPE/
:read !spell % | columnate
:global/pattern/p | l
:s/a/b/ | s/c/d | set

```

Historically, empty or <blank> filled lines in .exrc files and sourced files (as well as EXINIT variables and ex command scripts) were treated as default commands; that is, print commands. IEEE Std 1003.1-200x specifically requires that they be ignored when encountered in .exrc and sourced files to eliminate a common source of new user error.

Historically, ex commands with multiple adjacent (or <blank>-separated) vertical lines were handled oddly when executed from ex mode. For example, the command I I I <carriage-return>, when the cursor was on line 1, displayed lines 2,3 , and 5 of the file. In addition, the command I would only display the line after the next line, instead of the next two lines. The former worked more logically when executed from vi mode, and displayed lines 2, 3, and 4. IEEE Std 1003.1-200x requires the vi behavior; that is, a single default command and line number increment for each command separator, and trailing <newline>s after vertical-line separators are discarded.
Historically, ex permitted a single extra colon as a leading command character; for example, :g/pattern/:p was a valid command. IEEE Std 1003.1-200x generalizes this to require that any number of leading colon characters be stripped.
Historically, any prefix of the delete command could be followed without intervening <blank>s by a flag character because in the command \(\mathbf{d} \mathbf{p}, p\) is interpreted as the buffer \(p\). IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, the \(\mathbf{k}\) command could be followed by the mark name without intervening <blank>s. IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, the s command could be immediately followed by flag and option characters; for example, \(\mathbf{s} / \mathbf{e} / \mathrm{E} / \mathrm{l} \mid \operatorname{sgc} 3 \mathrm{p}\) was a valid command. However, flag characters could not stand alone; for example, the commands \(\mathbf{s p}\) and s 1 would fail, while the command sgp and s gl would succeed. (Obviously, the '\#' flag character was used as a delimiter character if it followed the command.) Another issue was that option characters had to precede flag characters even when
the command was fully specified; for example, the command s/e/E/pg would fail, while the command s/e/E/gp would succeed. IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, the first command name that had a prefix matching the input from the user was the executed command; for example, ve, ver, and vers all executed the version command. Commands were in a specific order, however, so that a matched append, not abbreviate. IEEE Std 1003.1-200x requires conformance to historical practice. The restriction on command search order for implementations with extensions is to avoid the addition of commands such that the historical prefixes would fail to work portably.
Historical implementations of \(e x\) and vi did not correctly handle multiple ex commands, separated by vertical-line characters, that entered or exited visual mode or the editor. Because implementations of \(v i\) exist that do not exhibit this failure mode, IEEE Std 1003.1-200x does not permit it.
The requirement that alphabetic command names consist of all following alphabetic characters up to the next non-alphabetic character means that alphabetic command names must be separated from their arguments by one or more non-alphabetic characters, normally a <blank> or '!' character, except as specified for the exceptions, the delete, \(\mathbf{k}\), and \(\mathbf{s}\) commands.

Historically, the repeated execution of the ex default print commands (<control>-D, eof, <newline>, <carriage-return>) erased any prompting character and displayed the next lines without scrolling the terminal; that is, immediately below any previously displayed lines. This provided a cleaner presentation of the lines in the file for the user. IEEE Std 1003.1-200x does not require this behavior because it may be impossible in some situations; however, implementations are strongly encouraged to provide this semantic if possible.
Historically, it was possible to change files in the middle of a command, and have the rest of the command executed in the new file; for example:
: edit +25 file.c s/abc/ABC \(/ 1\)
was a valid command, and the substitution was attempted in the newly edited file. IEEE Std 1003.1-200x requires conformance to historical practice. The following commands are examples that exercise the ex parser:
```

echo 'foo bar' > file1; echo 'foo/bar' > file2;
vi
: edit +1 $\mid$ s $/ /$ PIPE/ | w file1 | e file2 | $1 \mid \mathrm{s} / \backslash / /$ SLASH/ | wq

```

Historically, there was no protection in editor implementations to avoid ex global, v, @, or * commands changing edit buffers during execution of their associated commands. Because this would almost invariably result in catastrophic failure of the editor, and implementations exist that do exhibit these problems, IEEE Std 1003.1-200x requires that changing the edit buffer during a global or \(\mathbf{v}\) command, or during a @ or * command for which there will be more than a single execution, be an error. Implementations supporting multiple edit buffers simultaneously are strongly encouraged to apply the same semantics to switching between buffers as well.
The \(e x\) command quoting required by IEEE Std 1003.1-200x is a superset of the quoting in historical implementations of the editor. For example, it was not historically possible to escape a <blank> in a filename; for example, :edit foo \\\\bar would report that too many filenames had been entered for the edit command, and there was no method of escaping a <blank> in the first argument of an edit, ex, next, or visual command at all. IEEE Std 1003.1-200x extends historical practice, requiring that quoting behavior be made consistent across all ex commands, except for the map, unmap, abbreviate, and unabbreviate commands, which historically used <control>-V instead of backslashes for quoting. For those four commands, IEEE Std 1003.1-200x requires conformance to historical practice.
Backslash quoting in \(e x\) is non-intuitive. Backslash escapes are ignored unless they escape a
special character; for example, when performing file argument expansion, the string " \(\backslash \backslash \%\) " is equivalent to ' \\%', not " \(\backslash\) <current pathname>". This can be confusing for users because backslash is usually one of the characters that causes shell expansion to be performed, and therefore shell quoting rules must be taken into consideration. Generally, quoting characters are only considered if they escape a special character, and a quoting character must be provided for each layer of parsing for which the character is special. As another example, only a single backslash is necessary for the \(' \backslash l^{\prime}\) sequence in substitute replacement patterns, because the character ' \(l^{\prime}\) ' is not special to any parsing layer above it.
<control>-V quoting in ex is slightly different from backslash quoting. In the four commands where <control>-V quoting applies (abbreviate, unabbreviate, map, and unmap), any character may be escaped by a <control>-V whether it would have a special meaning or not. IEEE Std 1003.1-200x requires conformance to historical practice.
Historical implementations of the editor did not require delimiters within character classes to be escaped; for example, the command \(: s /[/] / / /\) on the string "xxx/yyy" would delete the \({ }^{\prime} /{ }^{\prime}\) from the string. IEEE Std 1003.1-200x disallows this historical practice for consistency and because it places a large burden on implementations by requiring that knowledge of regular expressions be built into the editor parser.

Historically, quoting <newline>s in ex commands was handled inconsistently. In most cases, the <newline> always terminated the command, regardless of any preceding escape character, because backslash characters did not escape <newline>s for most ex commands. However, some ex commands (for example, s, map, and abbreviation) permitted <newline>s to be escaped (although in the case of map and abbreviation, <control>-V characters escaped them instead of backslashes). This was true in not only the command line, but also .exrc and sourced files. For example, the command:
map \(=\) foo<control-V><newline>bar
would succeed, although it was sometimes difficult to get the <control>-V and the inserted <newline> passed to the ex parser. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that it be possible to escape <newline>s in \(e x\) commands at all times, using backslashes for most ex commands, and using <control>-V characters for the map and abbreviation commands. For example, the command print<newline>list is required to be parsed as the single command print<newline \(>\) list. While this differs from historical practice, IEEE Std 1003.1-200x developers believed it unlikely that any script or user depended on the historical behavior.

Historically, an error in a command specified using the -c option did not cause the rest of the -c commands to be discarded. IEEE Std 1003.1-200x disallows this for consistency with mapped keys, the @, global, source, and v commands, the EXINIT environment variable, and the .exrc files.

\section*{Input Editing in ex}

One of the common uses of the historical ex editor is over slow network connections. Editors that run in canonical mode can require far less traffic to and from, and far less processing on, the host machine, as well as more easily supporting block-mode terminals. For these reasons, IEEE Std 1003.1-200x requires that ex be implemented using canonical mode input processing, as was done historically.

IEEE Std 1003.1-200x does not require the historical 4 BSD input editing characters "word erase" or "literal next". For this reason, it is unspecified how they are handled by ex, although they must have the required effect. Implementations that resolve them after the line has been ended using a <newline> or <control>-M character, and implementations that rely on the underlying system terminal support for this processing, are both conforming. Implementations are strongly urged to use the underlying system functionality, if at all possible, for compatibility with other
system text input interfaces.
Historically, when the eof character was used to decrement the autoindent level, the cursor moved to display the new end of the autoindent characters, but did not move the cursor to a new line, nor did it erase the <control>-D character from the line. IEEE Std 1003.1-200x does not specify that the cursor remain on the same line or that the rest of the line is erased; however, implementations are strongly encouraged to provide the best possible user interface; that is, the cursor should remain on the same line, and any <control>-D character on the line should be erased.

IEEE Std 1003.1-200x does not require the historical 4 BSD input editing character "reprint", traditionally <control>-R, which redisplayed the current input from the user. For this reason, and because the functionality cannot be implemented after the line has been terminated by the user, IEEE Std 1003.1-200x makes no requirements about this functionality. Implementations are strongly urged to make this historical functionality available, if possible.
Historically, <control>-Q did not perform a literal next function in \(e x\), as it did in vi. IEEE Std 1003.1-200x requires conformance to historical practice to avoid breaking historical ex scripts and .exrc files.

\section*{eof}

Whether the eof character immediately modifies the autoindent characters in the prompt is left unspecified so that implementations can conform in the presence of systems that do not support this functionality. Implementations are encouraged to modify the line and redisplay it immediately, if possible.

The specification of the handling of the eof character differs from historical practice only in that eof characters are not discarded if they follow normal characters in the text input. Historically, they were always discarded.

\section*{Command Descriptions in ex}

Historically, several commands (for example, global, v, visual, s, write, wq, yank, !, <, >, \& , and ~) were executable in empty files (that is, the default address(es) were 0 ), or permitted explicit addresses of 0 (for example, 0 was a valid address, or 0,0 was a valid range). Addresses of 0 , or command execution in an empty file, make sense only for commands that add new text to the edit buffer or write commands (because users may wish to write empty files). IEEE Std 1003.1-200x requires this behavior for such commands and disallows it otherwise, for consistency and simplicity of specification.
A count to an ex command has been historically corrected to be no greater than the last line in a file; for example, in a five-line file, the command 1,6print would fail, but the command 1print300 would succeed. IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, the use of flags in ex commands could be obscure. General historical practice was as described by IEEE Std 1003.1-200x, but there were some special cases. For instance, the list, number, and print commands ignored trailing address offsets; for example, \(3 p+++\#\) would display line 3 , and 3 would be the current line after the execution of the command. The open and visual commands ignored both the trailing offsets and the trailing flags. Also, flags specified to the open and visual commands interacted badly with the list edit option, and setting and then unsetting it during the open/visual session would cause vi to stop displaying lines in the specified format. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit any of these exceptions to the general rule.
IEEE Std 1003.1-200x uses the word copy in several places when discussing buffers. This is not intended to imply implementation.
Historically, ex users could not specify numeric buffers because of the ambiguity this would
cause; for example, in the command 3 delete 2 , it is unclear whether 2 is a buffer name or a count. IEEE Std 1003.1-200x requires conformance to historical practice by default, but does not preclude extensions.
Historically, the contents of the unnamed buffer were frequently discarded after commands that did not explicitly affect it; for example, when using the edit command to switch files. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

The \(e x\) utility did not historically have access to the numeric buffers, and, furthermore, deleting lines in ex did not modify their contents. For example, if, after doing a delete in \(v i\), the user switched to \(e x\), did another delete, and then switched back to vi, the contents of the numeric buffers would not have changed. IEEE Std 1003.1-200x requires conformance to historical practice. Numeric buffers are described in the ex utility in order to confine the description of buffers to a single location in IEEE Std 1003.1-200x.
The metacharacters that trigger shell expansion in file arguments match historical practice, as does the method for doing shell expansion. Implementations wishing to provide users with the flexibility to alter the set of metacharacters are encouraged to provide a shellmeta string edit option.

Historically, ex commands executed from vi refreshed the screen when it did not strictly need to do so; for example, :!date >/dev/null does not require a screen refresh because the output of the UNIX date command requires only a single line of the screen. IEEE Std 1003.1-200x requires that the screen be refreshed if it has been overwritten, but makes no requirements as to how an implementation should make that determination. Implementations may prompt and refresh the screen regardless.

\section*{Abbreviate}

Historical practice was that characters that were entered as part of an abbreviation replacement were subject to map expansions, the showmatch edit option, further abbreviation expansions, and so on; that is, they were logically pushed onto the terminal input queue, and were not a simple replacement. IEEE Std 1003.1-200x requires conformance to historical practice. Historical practice was that whenever a non-word character (that had not been escaped by a <control>-V) was entered after a word character, vi would check for abbreviations. The check was based on the type of the character entered before the word character of the word/non-word pair that triggered the check. The word character of the word/non-word pair that triggered the check and all characters entered before the trigger pair that were of that type were included in the check, with the exception of <blank>s, which always delimited the abbreviation.
This means that, for the abbreviation to work, the lhs must end with a word character, there can be no transitions from word to non-word characters (or vice versa) other than between the last and next-to-last characters in the lhs, and there can be no <blank>s in the lhs. In addition, because of the historical quoting rules, it was impossible to enter a literal <control>-V in the lhs. IEEE Std 1003.1-200x requires conformance to historical practice. Historical implementations did not inform users when abbreviations that could never be used were entered; implementations are strongly encouraged to do so.

For example, the following abbreviations will work:
```

:ab (p REPLACE
:ab p REPLACE
:ab ((p REPLACE

```

The following abbreviations will not work:
```

:ab ( REPLACE
:ab (pp REPLACE

```

Historical practice is that words on the vi colon command line were subject to abbreviation
expansion, including the arguments to the abbrev (and more interestingly) the unabbrev command. Because there are implementations that do not do abbreviation expansion for the first argument to those commands, this is permitted, but not required, by IEEE Std 1003.1-200x. However, the following sequence:
:ab foo bar
:ab foo baz
resulted in the addition of an abbreviation of "baz" for the string "bar" in historical \(e x / v i\), and the sequence:
```

:ab fool bar
:ab foo2 bar
:unabbreviate foo2

```
deleted the abbreviation "foo1", not "foo2". These behaviors are not permitted by IEEE Std 1003.1-200x because they clearly violate the expectations of the user.
It was historical practice that <control>-V, not backslash, characters be interpreted as escaping subsequent characters in the abbreviate command. IEEE Std 1003.1-200x requires conformance to historical practice; however, it should be noted that an abbreviation containing a <blank> will never work.

\section*{Append}

Historically, any text following a vertical-line command separator after an append, change, or insert command became part of the insert text. For example, in the command:
:g/pattern/append|stuff1
a line containing the text "stufff " would be appended to each line matching pattern. It was also historically valid to enter:
```

:append|stuff1
stuff2
.

```
and the text on the ex command line would be appended along with the text inserted after it. There was an historical bug, however, that the user had to enter two terminating lines (the ' .' lines) to terminate text input mode in this case. IEEE Std 1003.1-200x requires conformance to historical practice, but disallows the historical need for multiple terminating lines.

\section*{Change}

See the RATIONALE for the append command. Historical practice for cursor positioning after the change command when no text is input, is as described in IEEE Std 1003.1-200x. However, one System V implementation is known to have been modified such that the cursor is positioned on the first address specified, and not on the line before the first address. IEEE Std 1003.1-200x disallows this modification for consistency.
Historically, the change command did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by IEEE Std 1003.1-200x.

\section*{Change Directory}

A common extension in ex implementations is to use the elements of a cdpath edit option as prefix directories for path arguments to chdir that are relative pathnames and that do not have '.' or ". ." as their first component. Elements in the cdpath edit option are colon-separated. The initial value of the cdpath edit option is the value of the shell CDPATH environment variable. This feature was not included in IEEE Std 1003.1-200x because it does not exist in any of the implementations considered historical practice.

\section*{Copy}

Historical implementations of ex permitted copies to lines inside of the specified range; for example, :2,5copy3 was a valid command. IEEE Std 1003.1-200x requires conformance to historical practice.

\section*{Delete}

IEEE Std 1003.1-200x requires support for the historical parsing of a delete command followed by flags, without any intervening <blank>s. For example:
1dp Deletes the first line and prints the line that was second.
1delep As for 1dp.
1d Deletes the first line, saving it in buffer \(p\).
1d p11 (Pee-one-ell.) Deletes the first line, saving it in buffer \(p\), and listing the line that was second.

\section*{Edit}

Historically, any ex command could be entered as a +command argument to the edit command, although some (for example, insert and append) were known to confuse historical implementations. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that any command be supported as an argument to the edit command.

Historically, the command argument was executed with the current line set to the last line of the file, regardless of whether the edit command was executed from visual mode or not. IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, the +command specified to the edit and next commands was delimited by the first <blank>, and there was no way to quote them. For consistency, IEEE Std 1003.1-200x requires that the usual ex backslash quoting be provided.
Historically, specifying the +command argument to the edit command required a filename to be specified as well; for example, :edit \(+\mathbf{1 0 0}\) would always fail. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this usage to fail for that reason.
Historically, only the cursor position of the last file edited was remembered by the editor. IEEE Std 1003.1-200x requires that this be supported; however, implementations are permitted to remember and restore the cursor position for any file previously edited.

\section*{File}

Historical versions of the ex editor file command displayed a current line and number of lines in the edit buffer of 0 when the file was empty, while the \(v i<c o n t r o l>-G\) command displayed a current line and number of lines in the edit buffer of 1 in the same situation. IEEE Std 1003.1-200x does not permit this discrepancy, instead requiring that a message be displayed indicating that the file is empty.

\section*{Global}

The two-pass operation of the global and \(\mathbf{v}\) commands is not intended to imply implementation, only the required result of the operation.
The current line and column are set as specified for the individual \(e x\) commands. This requirement is cumulative; that is, the current line and column must track across all the commands executed by the global or \(\mathbf{v}\) commands.

\section*{Insert}

See the RATIONALE for the append command.
Historically, insert could not be used with an address of zero; that is, not when the edit buffer was empty. IEEE Std 1003.1-200x requires that this command behavula 4 Twq

:map ab abcd
the characters "ab" were used as is and were not remapped, but the characters "cd" were mapped if appropriate. This can cause infinite loops in the vi mapping mechanisms. IEEE Std 1003.1-200x requires conformance to historical practice, and that such loops be interruptible.

Text input maps had the same problems with expanding the lhs for the ex map! and unmap! command as did the \(e x\) abbreviate and unabbreviate commands. See the RATIONALE for the \(e x\) abbreviate command. IEEE Std 1003.1-200x requires similar modification of some historical practice for the map and unmap commands, as described for the abbreviate and unabbreviate commands.

Historically, maps that were subsets of other maps behaved differently depending on the order in which they were defined. For example:
```

:map! ab short
:map! abc long

```
would always translate the characters "ab" to "short", regardless of how fast the characters "abc" were entered. If the entry order was reversed:
\(\begin{array}{ll}\text { :map! abc } & \text { long } \\ \text { :map! ab } & \text { short }\end{array}\)
the characters " ab " would cause the editor to pause, waiting for the completing ' c ' character, and the characters might never be mapped to "short". For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that the shortest match be used at all times.
The length of time the editor spends waiting for the characters to complete the lhs is unspecified because the timing capabilities of systems are often inexact and variable, and it may depend on other factors such as the speed of the connection. The time should be long enough for the user to be able to complete the sequence, but not long enough for the user to have to wait. Some implementations of \(v i\) have added a keytime option, which permits users to set the number of 0,1 seconds the editor waits for the completing characters. Because mapped terminal function and cursor keys tend to start with an \(<\mathrm{ESC}>\) character, and \(<\mathrm{ESC}>\) is the key ending \(v i\) text input mode, maps starting with \(<\mathrm{ESC}>\) characters are generally exempted from this timeout period, or, at least timed out differently.

\section*{Mark}

Historically, users were able to set the "previous context" marks explicitly. In addition, the ex commands " and" and the vi commands ",",", and " all referred to the same mark. In addition, the previous context marks were not set if the command, with which the address setting the mark was associated, failed. IEEE Std 1003.1-200x requires conformance to historical practice. Historically, if marked lines were deleted, the mark was also deleted, but would reappear if the change was undone. IEEE Std 1003.1-200x requires conformance to historical practice.
The description of the special events that set the ' and ' marks matches historical practice. For example, historically the command \(/ \mathbf{a} /, / \mathbf{b} /\) did not set the ' and ' marks, but the command \(/ \mathbf{a} / / / \mathbf{b} /\) delete did.

\section*{Next}

Historically, any ex command could be entered as a +command argument to the next command, although some (for example, insert and append) were known to confuse historical implementations. IEEE Std 1003.1-200x requires that any command be permitted and that it behave as specified. The next command can accept more than one file, so usage such as:
next 'ls [abc] '
is valid; it need not be valid for the edit or read commands, for example, because they expect only one filename.

Historically, the next command behaved differently from the :rewind command in that it ignored the force flag if the autowrite flag was set. For consistency, IEEE Std 1003.1-200x does not permit this behavior.
Historically, the next command positioned the cursor as if the file had never been edited before, regardless. IEEE Std 1003.1-200x does not permit this behavior, for consistency with the edit command.
Implementations wanting to provide a counterpart to the next command that edited the previous file have used the command prev[ious], which takes no file argument. IEEE Std 1003.1-200x does not require this command.

\section*{Open}

Historically, the open command would fail if the open edit option was not set. IEEE Std 1003.1-200x does not mention the open edit option and does not require this behavior. Some historical implementations do not permit entering open mode from open or visual mode, only from ex mode. For consistency, IEEE Std 1003.1-200x does not permit this behavior.
Historically, entering open mode from the command line (that is, vi +open) resulted in anomalous behaviors; for example, the ex file and set commands, and the vi command <control>-G did not work. For consistency, IEEE Std 1003.1-200x does not permit this behavior.
Historically, the open command only permitted \(/ / \prime\) characters to be used as the search pattern delimiter. For consistency, IEEE Std 1003.1-200x requires that the search delimiters used by the s, global, and \(\mathbf{v}\) commands be accepted as well.

\section*{Preserve}

The preserve command does not historically cause the file to be considered unmodified for the purposes of future commands that may exit the editor. IEEE Std 1003.1-200x requires conformance to historical practice.
Historical documentation stated that mail was not sent to the user when preserve was executed; however, historical implementations did send mail in this case. IEEE Std 1003.1-200x requires conformance to the historical implementations.

\section*{Print}

The writing of NUL by the print command is not specified as a special case because the standard developers did not want to require ex to support NUL characters. Historically, characters were displayed using the ARPA standard mappings, which are as follows:
1. Printable characters are left alone.
2. Control characters less than \(\backslash 177\) are represented as ' \(\wedge\) ' followed by the character offset from the ' \(\varrho^{\prime}\) character in the ASCII map; for example, \(\backslash 007\) is represented as \({ }^{\prime}{ }^{\wedge} \mathrm{G}^{\prime}\).
3. \177 is represented as \({ }^{\prime \wedge}\) ' followed by ' ?'.

The display of characters having their eighth bit set was less standard. Existing implementations use hex ( \(0 x 00\) ), octal ( \(\backslash 000\) ), and a meta-bit display. (The latter displayed bytes that had their eighth bit set as the two characters " \(\mathrm{M}-\) " followed by the seven-bit display as described above.) The latter probably has the best claim to historical practice because it was used for the \(-\mathbf{v}\) option of 4 BSD and 4 BSD-derived versions of the cat utility since 1980.

No specific display format is required by IEEE Std 1003.1-200x.
Explicit dependence on the ASCII character set has been avoided where possible, hence the use of the phrase an "implementation-defined multi-character sequence" for the display of nonprintable characters in preference to the historical usage of, for instance, " "I" for the <tab>. Implementations are encouraged to conform to historical practice in the absence of any strong reason to diverge.
Historically, all ex commands beginning with the letter ' p ' could be entered using capitalized versions of the commands; for example, P[rint], Pre[serve], and Pu[t] were all valid command names. IEEE Std 1003.1-200x permits, but does not require, this historical practice because capital forms of the commands are used by some implementations for other purposes.

\section*{Put}

Historically, an ex put command, executed from open or visual mode, was the same as the open or visual mode \(\mathbf{P}\) command, if the buffer was named and was cut in character mode, and the same as the \(\mathbf{p}\) command if the buffer was named and cut in line mode. If the unnamed buffer was the source of the text, the entire line from which the text was taken was usually put, and the buffer was handled as if in line mode, but it was possible to get extremely anomalous behavior. In addition, using the \(\mathbf{Q}\) command to switch into ex mode, and then doing a put often resulted in errors as well, such as appending text that was unrelated to the (supposed) contents of the buffer. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit these behaviors. All ex put commands are required to operate in line mode, and the contents of the buffers are not altered by changing the mode of the editor.

\section*{Read}

Historically, an ex read command executed from open or visual mode, executed in an empty file, left an empty line as the first line of the file. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior. Historically, a read in open or visual mode from a program left the cursor at the last line read in, not the first. For consistency, IEEE Std 1003.1-200x does not permit this behavior.
Historical implementations of ex were unable to undo read commands that read from the output of a program. For consistency, IEEE Std 1003.1-200x does not permit this behavior.
Historically, the \(e x\) and \(v i\) message after a successful read or write command specified "characters", not "bytes". IEEE Std 1003.1-200x requires that the number of bytes be displayed, not the number of characters, because it may be difficult in multi-byte implementations to determine the number of characters read. Implementations are encouraged to clarify the message displayed to the user.

Historically, reads were not permitted on files other than type regular, except that FIFO files could be read (probably only because they did not exist when \(e x\) and \(v i\) were originally written). Because the historical ex evaluated read! and read! equivalently, there can be no optional way to force the read. IEEE Std 1003.1-200x permits, but does not require, this behavior.

\section*{Recover}

Some historical implementations of the editor permitted users to recover the edit buffer contents from a previous edit session, and then exit without saving those contents (or explicitly discarding them). The intent of IEEE Std 1003.1-200x in requiring that the edit buffer be treated as already modified is to prevent this user error.

\section*{Rewind}

Historical implementations supported the rewind command when the user was editing the first file in the list; that is, the file that the rewind command would edit. IEEE Std 1003.1-200x requires conformance to historical practice.

\section*{Substitute}

Historically, ex accepted an \(\mathbf{r}\) option to the \(\mathbf{s}\) command. The effect of the \(\mathbf{r}\) option was to use the last regular expression used in any command as the pattern, the same as the \(\sim\) command. The \(\mathbf{r}\) option is not required by IEEE Std 1003.1-200x. Historically, the \(\mathbf{c}\) and \(\mathbf{g}\) options were toggled; for example, the command :s/abc/def/ was the same as s/abc/def/ccccgggg. For simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.
The tilde command is often used to replace the last search RE. For example, in the sequence:
```

s/red/blue/
/green

```
the \(\sim\) command is equivalent to:
s/green/blue/
Historically, ex accepted all of the following forms:
s/abc/def/
s/abc/def
s/abc/
s/abc
IEEE Std 1003.1-200x requires conformance to this historical practice.
The s command presumes that the character only occupies a single column in the display. Much of the ex and \(v i\) specification presumes that the <space> only occupies a single column in the display. There are no known character sets for which this is not true.
Historically, the final column position for the substitute commands was based on previous column movements, a search for a pattern followed by a substitution would leave the column position unchanged, while a 0 command followed by a substitution would change the column position to the first non-<blank>. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that the final column position always be set to the first non-<blank>.

\section*{Set}

Historical implementations redisplayed all of the options for each occurrence of the all keyword. IEEE Std 1003.1-200x permits, but does not require, this behavior.

\section*{Tag}

No requirement is made as to where \(e x\) and \(v i\) shall look for the file referenced by the tag entry. Historical practice has been to look for the path found in the tags file, based on the current directory. A useful extension found in some implementations is to look based on the directory containing the tags file that held the entry, as well. No requirement is made as to which reference for the tag in the tags file is used. This is deliberate, in order to permit extensions such as multiple entries in a tags file for a tag.

Because users often specify many different tags files, some of which need not be relevant or exist at any particular time, IEEE Std 1003.1-200x requires that error messages about problem tags files be displayed only if the requested tag is not found, and then, only once for each time that the tag edit option is changed.
The requirement that the current edit buffer be unmodified is only necessary if the file indicated by the tag entry is not the same as the current file (as defined by the current pathname). Historically, the file would be reloaded if the filename had changed, as well as if the filename was different from the current pathname. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior, requiring that the name be the only factor in the decision.

Historically, vi only searched for tags in the current file from the current cursor to the end of the file, and therefore, if the wrapscan option was not set, tags occurring before the current cursor were not found. IEEE Std 1003.1-200x considers this a bug, and implementations are required to search for the first occurrence in the file, regardless.

\section*{Undo}

The undo description deliberately uses the word "modified". The undo command is not intended to undo commands that replace the contents of the edit buffer, such as edit, next, tag, or recover.
Cursor positioning after the undo command was inconsistent in the historical \(v i\), sometimes attempting to restore the original cursor position (global, undo, and \(\mathbf{v}\) commands), and sometimes, in the presence of maps, placing the cursor on the last line added or changed instead of the first. IEEE Std 1003.1-200x requires a simplified behavior for consistency and simplicity of specification.

\section*{Version}

The version command cannot be exactly specified since there is no widely-accepted definition of what the version information should contain. Implementations are encouraged to do something reasonably intelligent.

\section*{Write}

Historically, the \(e x\) and \(v i\) message after a successful read or write command specified "characters", not "bytes". IEEE Std 1003.1-200x requires that the number of bytes be displayed, not the number of characters because it may be difficult in multi-byte implementations to determine the number of characters written. Implementations are encouraged to clarify the message displayed to the user.
Implementation-defined tests are permitted so that implementations can make additional checks; for example, for locks or file modification times.
Historically, attempting to append to a nonexistent file caused an error. It has been left unspecified in IEEE Std 1003.1-200x to permit implementations to let the write succeed, so that the append semantics are similar to those of the historical csh.
Historical vi permitted empty edit buffers to be written. However, since the way vi got around
dealing with "empty" files was to always have a line in the edit buffer, no matter what, it wrote them as files of a single, empty line. IEEE Std 1003.1-200x does not permit this behavior.
Historically, ex restored standard output and standard error to their values as of when ex was invoked, before writes to programs were performed. This could disturb the terminal configuration as well as be a security issue for some terminals. IEEE Std 1003.1-200x does not permit this, requiring that the program output be captured and displayed as if by the ex print command.

\section*{Adjust Window}

Historically, the line count was set to the value of the scroll option if the type character was end-of-file. This feature was broken on most historical implementations long ago, however, and is not documented anywhere. For this reason, IEEE Std 1003.1-200x is resolutely silent.
Historically, the \(\mathbf{z}\) command was <blank>-sensitive and \(\mathbf{z}+\) and \(\mathbf{z}\) - did different things than \(\mathbf{z +}\) and \(\mathbf{z}\) - because the type could not be distinguished from a flag. (The commands \(\mathbf{z}\). and \(\mathbf{z}=\) were historically invalid.) IEEE Std 1003.1-200x requires conformance to this historical practice.
Historically, the \(\mathbf{z}\) command was further <blank>-sensitive in that the count could not be <blank>-delimited; for example, the commands \(\mathbf{z}=5\) and \(\mathbf{z}-5\) were also invalid. Because the count is not ambiguous with respect to either the type character or the flags, this is not permitted by IEEE Std 1003.1-200x.

\section*{Escape}

Historically, ex filter commands only read the standard output of the commands, letting standard error appear on the terminal as usual. The vi utility, however, read both standard output and standard error. IEEE Std 1003.1-200x requires the latter behavior for both ex and vi, for consistency.

\section*{Shift Left and Shift Right}

Historically, it was possible to add shift characters to increase the effect of the command; for example, \(\lll\) outdented (or \(\ggg\) indented) the lines 3 levels of indentation instead of the default 1. IEEE Std 1003.1-200x requires conformance to historical practice.

\section*{<control>-D}

Historically, the <control>-D command erased the prompt, providing the user with an unbroken presentation of lines from the edit buffer. This is not required by IEEE Std 1003.1-200x; implementations are encouraged to provide it if possible. Historically, the <control>-D command took, and then ignored, a count. IEEE Std 1003.1-200x does not permit this behavior.

\section*{Write Line Number}

Historically, the \(e x=\) command, when executed in \(e x\) mode in an empty edit buffer, reported 0 , and from open or visual mode, reported 1. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

\section*{Execute}

Historically, ex did not correctly handle the inclusion of text input commands (that is, append, insert, and change) in executed buffers. IEEE Std 1003.1-200x does not permit this exclusion for consistency.
Historically, the logical contents of the buffer being executed did not change if the buffer itself were modified by the commands being executed; that is, buffer execution did not support selfmodifying code. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the @ command took a range of lines, and the @ buffer was executed once per line, with the current line \(\left({ }^{\prime} .^{\prime}\right)\) set to each specified line. IEEE Std 1003.1-200x requires conformance to historical practice.
Some historical implementations did not notice if errors occurred during buffer execution. This, coupled with the ability to specify a range of lines for the ex @ command, makes it trivial to cause them to drop core. IEEE Std 1003.1-200x requires that implementations stop buffer execution if any error occurs, if the specified line doesn't exist, or if the contents of the edit buffer itself are replaced (for example, the buffer executes the ex :edit command).

\section*{Regular Expressions in ex}

Historical practice is that the characters in the replacement part of the last s command-that is, those matched by entering \(\mathrm{a}^{\prime \sim}{ }^{\prime}\) in the regular expression-were not further expanded by the regular expression engine. So, if the characters contained the string "a., " they would match ' \(a\) ' followed by ". " " and not ' \(a\) ' followed by any character. IEEE Std 1003.1-200x requires conformance to historical practice.

\section*{Edit Options in ex}

The following paragraphs describe the historical behavior of some edit options that were not, for whatever reason, included in IEEE Std 1003.1-200x. Implementations are strongly encouraged to only use these names if the functionality described here is fully supported.
extended The extended edit option has been used in some implementations of vi to provide extended regular expressions instead of basic regular expressions This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice.
flash The flash edit option historically caused the screen to flash instead of beeping on error. This option was omitted from IEEE Std 1003.1-200x because it is not found in some historical implementations.
hardtabs The hardtabs edit option historically defined the number of columns between hardware tab settings. This option was omitted from IEEE Std 1003.1-200x because it was believed to no longer be generally useful.
modeline The modeline (sometimes named modelines) edit option historically caused ex or vi to read the five first and last lines of the file for editor commands. This option is a security problem, and vendors are strongly encouraged to delete it from historical implementations.
open The open edit option historically disallowed the ex open and visual commands. This edit option was omitted because these commands are required by IEEE Std 1003.1-200x.
optimize The optimize edit option historically expedited text throughput by setting the terminal to not do automatic <carriage-return>s when printing more than one logical line of output. This option was omitted from IEEE Std 1003.1-200x because it was intended for terminals without addressable cursors, which are rarely, if ever, still used.
ruler The ruler edit option has been used in some implementations of \(v i\) to present a current row/column ruler for the user. This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice.
sourceany The sourceany edit option historically caused \(e x\) or \(v i\) to source start-up files that were owned by users other than the user running the editor. This option is a security problem, and vendors are strongly encouraged to remove it from their implementations.
timeout The timeout edit option historically enabled the (now standard) feature of only waiting for a short period before returning keys that could be part of a macro. This feature was omitted from IEEE Std 1003.1-200x because its behavior is now standard, it is not widely useful, and it was rarely documented.
verbose The verbose edit option has been used in some implementations of \(v i\) to cause \(v i\) to output error messages for common errors; for example, attempting to move the cursor past the beginning or end of the line instead of only alerting the screen. (The historical vi only alerted the terminal and presented no message for such errors. The historical editor option terse did not select when to present error messages, it only made existing error messages more or less verbose.) This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they wish to provide error messages for naive users.
wraplen The wraplen edit option has been used in some implementations of \(v i\) to specify an automatic margin measured from the left margin instead of from the right margin. This is useful when multiple screen sizes are being used to edit a single file. This option was omitted from IEEE Std 1003.1-200x because it is not widespread historical practice; however, implementors are encouraged to use it if they add this functionality.
autoindent, ai
Historically, the command 0a did not do any autoindentation, regardless of the current indentation of line 1. IEEE Std 1003.1-200x requires that any indentation present in line 1 be used.

\section*{autoprint, ap}

Historically, the autoprint edit option was not completely consistent or based solely on modifications to the edit buffer. Exceptions were the read command (when reading from a file, but not from a filter), the append, change, insert, global, and \(\mathbf{v}\) commands, all of which were not affected by autoprint, and the tag command, which was affected by autoprint. IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, the autoprint option only applied to the last of multiple commands entered using vertical-bar delimiters; for example, delete <newline> was affected by autoprint, but deletelversion <newline> was not. IEEE Std 1003.1-200x requires conformance to historical practice.
autowrite, aw
Appending the '!' character to the ex next command to avoid performing an automatic write was not supported in historical implementations. IEEE Std 1003.1-200x requires that the behavior match the other ex commands for consistency.

\section*{ignorecase, ic}

Historical implementations of case-insensitive matching (the ignorecase edit option) lead to counterintuitive situations when uppercase characters were used in range expressions. Historically, the process was as follows:
1. Take a line of text from the edit buffer.
2. Convert uppercase to lowercase in text line.
3. Convert uppercase to lowercase in regular expressions, except in character class specifications.
4. Match regular expressions against text.

This would mean that, with ignorecase in effect, the text:
```

The cat sat on the mat

```
would be matched by
```

/^the/

```
but not by:
\[
/^{\wedge}[\mathrm{A}-\mathrm{Z}] \text { he/ }
\]

For consistency with other commands implementing regular expressions, IEEE Std 1003.1-200x does not permit this behavior.

\section*{paragraphs, para}

The ISO POSIX-2: 1993 standard made the default paragraphs and sections edit options implementation-defined, arguing they were historically oriented to the UNIX system troff text formatter, and a "portable user" could use the \(\{\},,[1] l,,(\), and ) commands in open or visual mode and have the cursor stop in unexpected places. IEEE Std 1003.1-200x specifies their values in the POSIX locale because the unusual grouping (they only work when grouped into two characters at a time) means that they cannot be used for general-purpose movement, regardless.

\section*{readonly}

Implementations are encouraged to provide the best possible information to the user as to the read-only status of the file, with the exception that they should not consider the current special privileges of the process. This provides users with a safety net because they must force the overwrite of read-only files, even when running with additional privileges.

The readonly edit option specification largely conforms to historical practice. The only difference is that historical implementations did not notice that the user had set the readonly edit option in cases where the file was already marked read-only for some reason, and would therefore reinitialize the readonly edit option the next time the contents of the edit buffer were replaced. This behavior is disallowed by IEEE Std 1003.1-200x.

\section*{report}

The requirement that lines copied to a buffer interact differently than deleted lines is historical practice. For example, if the report edit option is set to 3, deleting 3 lines will cause a report to be written, but 4 lines must be copied before a report is written.
The requirement that the \(e x\) global, \(\mathbf{v}\), open, undo, and visual commands present reports based on the total number of lines added or deleted during the command execution, and that commands executed by the global and \(\mathbf{v}\) commands not present reports, is historical practice. IEEE Std 1003.1-200x extends historical practice by requiring that buffer execution be treated similarly. The reasons for this are two-fold. Historically, only the report by the last command executed from the buffer would be seen by the user, as each new report would overwrite the last. In addition, the standard developers believed that buffer execution had more in common with global and \(\mathbf{v}\) commands than it did with other ex commands, and should behave similarly, for consistency and simplicity of specification.

\section*{showmatch, sm}

The length of time the cursor spends on the matching character is unspecified because the timing capabilities of systems are often inexact and variable. The time should be long enough for the user to notice, but not long enough for the user to become annoyed. Some implementations of \(v i\) have added a matchtime option that permits users to set the number of 0,1 second intervals the cursor pauses on the matching character.

\section*{showmode}

The showmode option has been used in some historical implementations of \(e x\) and \(v i\) to display the current editing mode when in open or visual mode. The editing modes have generally included "command" and "input", and sometimes other modes such as "replace"

\section*{tags}

The default path for tags files is left unspecified as implementations may have their own tags implementations that do not correspond to the historical ones. The default tags option value should probably at least include the file ./tags.

\section*{term}

Historical implementations of \(e x\) and \(v i\) ignored changes to the term edit option after the initial terminal information was loaded. This is permitted by IEEE Std 1003.1-200x; however, implementations are encouraged to permit the user to modify their terminal type at any time.

\section*{terse}

Historically, the terse edit option optionally provided a shorter, less descriptive error message, for some error messages. This is permitted, but not required, by IEEE Std 1003.1-200x. Historically, most common visual mode errors (for example, trying to move the cursor past the end of a line) did not result in an error message, but simply alerted the terminal. Implementations wishing to provide messages for novice users are urged to do so based on the edit option verbose, and not terse.

\section*{window}

In historical implementations, the default for the window edit option was based on the baud rate as follows:
1. If the baud rate was less than 1200 , the edit option w300 set the window value; for example, the line:
```

set w300=12

```
would set the window option to 12 if the baud rate was less than 1200 .
2. If the baud rate was equal to 1200 , the edit option w1200 set the window value.
3. If the baud rate was greater than 1200, the edit option \(\mathbf{w} 9600\) set the window value.

The w300, w1200, and w9600 options do not appear in IEEE Std 1003.1-200x because of their dependence on specific baud rates.
In historical implementations, the size of the window displayed by various commands was related to, but not necessarily the same as, the window edit option. For example, the size of the window was set by the ex command visual 10, but it did not change the value of the window edit option. However, changing the value of the window edit option did change the number of lines that were displayed when the screen was repainted. IEEE Std 1003.1-200x does not permit this behavior in the interests of consistency and simplicity of specification, and requires that all commands that change the number of lines that are displayed do it by setting the value of the window edit option.

\section*{wrapmargin, wm}

Historically, the wrapmargin option did not affect maps inserting characters that also had associated counts; for example :map K 5aABC DEF. Unfortunately, there are widely used maps that depend on this behavior. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.
Historically, wrapmargin was calculated using the column display width of all characters on the screen. For example, an implementation using " \(I\) " to represent <tab>s when the list edit option was set, where ' ' ' and ' I' each took up a single column on the screen, would calculate the wrapmargin based on a value of 2 for each <tab>. The number edit option similarly changed the effective length of the line as well. IEEE Std 1003.1-200x requires conformance to
historical practice.
Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

\section*{FUTURE DIRECTIONS}

None.

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The obsolescent SYNOPSIS is removed, removing the + command and - options.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- In the map command description, the sequence \#digit is added.
- The directory, edcompatible, redraw, and slowopen edit options are added.

The ex utility is extensively changed for alignment with the IEEE P1003.2b draft standard. This includes changes as a result of the IEEE PASC Interpretations 1003.2 \#31, \#38, \#49, \#50, \#51, \#52, \#55, \#56, \#57, \#61, \#62, \#63, \#64, \#65, and \#78.

The -1 option is removed.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/23 is applied, correcting a URL.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/8 is applied, making an editorial correction in the EXTENDED DESCRIPTION.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/9 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

\section*{Issue 7}

Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying the behavior if an operand is ' - '

Austin Group Interpretation 1003.1-2001 \#036 is applied, clarifying the behavior for BREs.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
expand - convert tabs to spaces

\section*{SYNOPSIS}
```

expand [-t tablist] [file...]

```

\section*{DESCRIPTION}

The expand utility shall write files or the standard input to the standard output with <tab>s replaced with one or more <space>s needed to pad to the next tab stop. Any <backspace>s shall be copied to the output and cause the column position count for tab stop calculations to be decremented; the column position count shall not be decremented below zero.

\section*{OPTIONS}

The expand utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-t tablist Specify the tab stops. The application shall ensure that the argument tablist consists of either a single positive decimal integer or a list of tabstops. If a single number is given, tabs shall be set that number of column positions apart instead of the default 8.

If a list of tabstops is given, the application shall ensure that it consists of a list of two or more positive decimal integers, separated by <blank>s or commas, in ascending order. The tabs shall be set at those specific column positions. Each tab stop \(N\) shall be an integer value greater than zero, and the list is in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position \(N\) shall cause the next character output to be in the \((N+1)\) th column position on that line.

In the event of expand having to process a <tab> at a position beyond the last of those specified in a multiple tab-stop list, the <tab> shall be replaced by a single <space> in the output.

\section*{OPERANDS}

The following operand shall be supported:
file The pathname of a text file to be used as input.

\section*{STDIN}

See the INPUT FILES section.

\section*{INPUT FILES}

Input files shall be text files.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of expand:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab>s and <space>s, and for the determination of the width in column positions each character would occupy on an output device.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The standard output shall be equivalent to the input files with <tab>s converted into the appropriate number of <space>s.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

The expand utility shall terminate with an error message and non-zero exit status upon encountering difficulties accessing one of the file operands.

\section*{APPLICATION USAGE}

None.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The expand utility is useful for preprocessing text files (before sorting, looking at specific columns, and so on) that contain \(<\) tab \(>\) s.
See the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.103, Column Position.
The tablist option-argument consists of integers in ascending order. Utility Syntax Guideline 8 mandates that expand shall accept the integers (within the single argument) separated using either commas or <blank>s.

Earlier versions of this standard allowed the following form in the SYNOPSIS:
expand [-tabstop][-tab1,tab2,...,tabn][file ...]
This form is no longer specified by this standard but may be present in some implementations.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
tabs, unexpand
CHANGE HISTORY
First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
The obsolescent SYNOPSIS is removed.
The LC_CTYPE environment variable description is updated to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied.
The expand utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
expr - evaluate arguments as an expression

\section*{SYNOPSIS}
```

expr operand

```

\section*{DESCRIPTION}

The expr utility shall evaluate an expression and write the result to standard output.
OPTIONS
None.
OPERANDS
The single expression evaluated by expr shall be formed from the operands, as described in the EXTENDED DESCRIPTION section. The application shall ensure that each of the expression operator symbols:
and the symbols integer and string in the table are provided as separate arguments to expr.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of expr:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions and by the string comparison operators.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The expr utility shall evaluate the expression and write the result, followed by a <newline>, to standard output.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

The formation of the expression to be evaluated is shown in the following table. The symbols expr, expr1, and expr2 represent expressions formed from integer and string symbols and the expression operator symbols (all separate arguments) by recursive application of the constructs described in the table. The expressions are listed in order of increasing precedence, with equalprecedence operators grouped between horizontal lines. All of the operators shall be leftassociative.
\begin{tabular}{|c|c|}
\hline Expression & Description \\
\hline expr1 | expr2 & Returns the evaluation of expr1 if it is neither null nor zero; otherwise, returns the evaluation of expr 2 if it is not null; otherwise, zero. \\
\hline expr 1 \& expr 2 & Returns the evaluation of expr 1 if neither expression evaluates to null or zero; otherwise, returns zero. \\
\hline \[
\begin{aligned}
& \operatorname{expr} 1=\text { expr } 2 \\
& \text { expr } 1>\operatorname{expr} 2 \\
& \text { expr } 1>=\text { expr } 2 \\
& \text { expr } 1<\operatorname{expr} 2 \\
& \text { expr } 1<=\operatorname{expr} 2 \\
& \text { expr } 1!=\operatorname{expr} 2
\end{aligned}
\] & \begin{tabular}{l}
Returns the result of a decimal integer comparison if both arguments are integers; otherwise, returns the result of a string comparison using the locale-specific collation sequence. The result of each comparison is 1 if the specified relationship is true, or 0 if the relationship is false. \\
Equal. \\
Greater than. \\
Greater than or equal. \\
Less than. \\
Less than or equal. \\
Not equal.
\end{tabular} \\
\hline \[
\begin{aligned}
& \operatorname{expr} 1+\operatorname{expr} 2 \\
& \operatorname{expr} 1-\operatorname{expr} 2
\end{aligned}
\] & Addition of decimal integer-valued arguments. Subtraction of decimal integer-valued arguments. \\
\hline \begin{tabular}{l}
expr1 * expr2 \\
expr1 / expr2 \\
expr1 \% expr2
\end{tabular} & \begin{tabular}{l}
Multiplication of decimal integer-valued arguments. Integer division of decimal integer-valued arguments, producing an integer result. \\
Remainder of integer division of decimal integer-valued arguments.
\end{tabular} \\
\hline expr1 : expr2 & Matching expression; see below. \\
\hline ( expr ) & Grouping symbols. Any expression can be placed within parentheses. Parentheses can be nested to a depth of \{EXPR_NEST_MAX\}. \\
\hline \begin{tabular}{l}
integer \\
string
\end{tabular} & \begin{tabular}{l}
An argument consisting only of an (optional) unary minus followed by digits. \\
A string argument; see below.
\end{tabular} \\
\hline
\end{tabular}

\section*{Matching Expression}

The ':' matching operator shall compare the string resulting from the evaluation of expr1 with the regular expression pattern resulting from the evaluation of expr2. Regular expression syntax shall be that defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions, except that all patterns are anchored to the beginning of the string (that is, only sequences starting at the first character of a string are matched by the regular expression) and, therefore, it is unspecified whether \({ }^{\prime}{ }^{\prime \prime}\) is a special character in that context. Usually, the matching operator shall return a string representing the number of characters matched ( \({ }^{\prime} 0^{\prime}\) on failure). Alternatively, if the pattern contains at least one regular expression subexpression " \(\ \backslash(\ldots \backslash)]\) ", the string matched by the back-reference expression " \(\backslash 1\) " shall be returned. If the back-reference expression " \(\backslash 1\) " does not match, then the null string shall be returned.

\section*{String Operand}

A string argument is an argument that cannot be identified as an integer argument or as one of the expression operator symbols shown in the OPERANDS section.
The use of string arguments length, substr, index, or match produces unspecified results.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 The expression evaluates to neither null nor zero.
1 The expression evaluates to null or zero.
2 Invalid expression.
\(>2\) An error occurred.
CONSEQUENCES OF ERRORS

\section*{Default.}

\section*{APPLICATION USAGE}

After argument processing by the shell, expr is not required to be able to tell the difference between an operator and an operand except by the value. If " \(\$\) a " is \({ }^{\prime}=\prime\), the command:
\(\operatorname{expr} \$ a=\prime=\prime\)
looks like.
\(\operatorname{expr}===\)
as the arguments are passed to expr (and they all may be taken as the \({ }^{\prime}={ }^{\prime}\) operator). The following works reliably:
```

expr X\$a = X=

```

Also note that this volume of IEEE Std 1003.1-200x permits implementations to extend utilities. The expr utility permits the integer arguments to be preceded with a unary minus. This means that an integer argument could look like an option. Therefore, the conforming application must employ the "--" construct of Guideline 10 of the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines to protect its operands if there is any chance the first operand might be a negative integer (or any string with a leading minus).

\section*{EXAMPLES}

The expr utility has a rather difficult syntax:
- Many of the operators are also shell control operators or reserved words, so they have to be escaped on the command line.
- Each part of the expression is composed of separate arguments, so liberal usage of <blank>s is required. For example:
\begin{tabular}{|c|c|}
\hline Invalid & Valid \\
\hline \[
\begin{aligned}
& \operatorname{expr} 1+2 \\
& \operatorname{expr} 11+2 \text { " } \\
& \operatorname{expr} 1+(2 \text { * } 3)
\end{aligned}
\] & \[
\begin{aligned}
& \operatorname{expr} 1+2 \\
& \operatorname{expr} 1+2 \\
& \operatorname{expr} 1+\backslash(2 \backslash * 3 \backslash)
\end{aligned}
\] \\
\hline
\end{tabular}

In many cases, the arithmetic and string features provided as part of the shell command language are easier to use than their equivalents in expr. Newly written scripts should avoid expr in favor of the new features within the shell; see Section 2.5 and Section 2.6.4 (on page 41).
The following command:
\(a=\$(\operatorname{expr} \$ \mathrm{a}+1)\)
adds 1 to the variable \(a\).
The following command, for "\$a" equal to either /usr/abc/file or just file:
```

expr \$a : '.*/$.*$' \| \$a

```
returns the last segment of a pathname (that is, file). Applications should avoid the character '/' used alone as an argument; expr may interpret it as the division operator.
The following command:
```

expr "//\$a" : '.*/$.*$'

```
is a better representation of the previous example. The addition of the "//" characters eliminates any ambiguity about the division operator and simplifies the whole expression. Also note that pathnames may contain characters contained in the IFS variable and should be quoted to avoid having "\$a" expand into multiple arguments.

The following command:
expr/"\$VAR" : '.**
returns the number of characters in VAR.

\section*{RATIONALE}

In an early proposal, EREs were used in the matching expression syntax. This was changed to BREs to avoid breaking historical applications.
The use of a leading circumflex in the BRE is unspecified because many historical implementations have treated it as a special character, despite their system documentation. For example:
expr foo : `foo expr ^foo : `foo
return 3 and 0 , respectively, on those systems; their documentation would imply the reverse. Thus, the anchoring condition is left unspecified to avoid breaking historical scripts relying on this undocumented feature.

\section*{FUTURE DIRECTIONS}

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/24 is applied, changing the STDERR section from "None." to "Not used." for alignment with Section 1.11 (on page 18).

\section*{NAME}
fc - process the command history list

\section*{SYNOPSIS}
```

UP

```
```

fc [-r] [-e editor] [first[last]]

```
fc [-r] [-e editor] [first[last]]
    fc -l [-nr] [first[last]]
    fc -l [-nr] [first[last]]
    fc -s [old=new] [first]
```

    fc -s [old=new] [first]
    ```

\section*{DESCRIPTION}

The fc utility shall list, or shall edit and re-execute, commands previously entered to an interactive sh.

The command history list shall reference commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command shall not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches an implementation-defined upper limit, which shall be no smaller than the value in HISTSIZE or 32767 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, \(f c\) shall maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32766,32767 , 1 (wrapped), and 2 as they are executed, command 32767 is considered the command previous to 1 , even though its number is higher.
When commands are edited (when the -1 option is not specified), the resulting lines shall be entered at the end of the history list and then re-executed by sh. The fc command that caused the editing shall not be entered into the history list. If the editor returns a non-zero exit status, this shall suppress the entry into the history list and the command re-execution. Any command line variable assignments or redirection operators used with \(f c\) shall affect both the \(f c\) command itself as well as the command that results; for example:
fc -s -- -1 2>/dev/null
reinvokes the previous command, suppressing standard error for both \(f c\) and the previous command.

\section*{OPTIONS}

The \(f c\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-e editor Use the editor named by editor to edit the commands. The editor string is a utility name, subject to search via the PATH variable (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables). The value in the FCEDIT variable shall be used as a default when \(-\mathbf{e}\) is not specified. If FCEDIT is null or unset, \(e d\) shall be used as the editor.
-1 (The letter ell.) List the commands rather than invoking an editor on them. The commands shall be written in the sequence indicated by the first and last operands, as affected by \(-\mathbf{r}\), with each command preceded by the command number.
Suppress command numbers when listing with \(\mathbf{- 1}\).
\begin{tabular}{lll}
17109 & \(-\mathbf{r}\) & \begin{tabular}{l} 
Reverse the order of the commands listed (with \(-\mathbf{1})\) or edited (with neither \(-\mathbf{1}\) nor \\
17110
\end{tabular} \\
17111 & \(-\mathbf{s})\). \\
Re-execute the command without invoking an editor.
\end{tabular}

\section*{OPERANDS}

The following operands shall be supported:
first, last Select the commands to list or edit. The number of previous commands that can be accessed shall be determined by the value of the HISTSIZE variable. The value of first or last or both shall be one of the following:
[+]number A positive number representing a command number; command numbers can be displayed with the -1 option.
-number
A negative decimal number representing the command that was executed number of commands previously. For example, -1 is the immediately previous command.
string A string indicating the most recently entered command that begins with that string. If the old \(=\) new operand is not also specified with -s, the string form of the first operand cannot contain an embedded equal sign.

When the synopsis form with -s is used:
- If first is omitted, the previous command shall be used.

For the synopsis forms without -s:
- If last is omitted, last shall default to the previous command when \(-\mathbf{1}\) is specified; otherwise, it shall default to first.
- If first and last are both omitted, the previous 16 commands shall be listed or the previous single command shall be edited (based on the -1 option).
- If first and last are both present, all of the commands from first to last shall be edited (without -1 ) or listed (with -1 ). Editing multiple commands shall be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If first represents a newer command than last, the commands shall be listed or edited in reverse sequence, equivalent to using -r. For example, the following commands on the first line are equivalent to the corresponding commands on the second:
\(\begin{array}{llllll}\text { fc } \\ \text { fc }\end{array} \quad-r \begin{array}{llll}10 & 20 \\ 20 & 10\end{array} \quad \begin{array}{llll}30 & 40 \\ \text { fc }-r & 40 & 30\end{array}\)
-When a range of commands is used, it shall not be an error to specify first or last values that are not in the history list; \(f c\) shall substitute the value representing the oldest or newest command in the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10 :
fc -1
fc 199
shall list and edit, respectively, all ten commands.
old=new \(\quad\) Replace the first occurrence of string old in the commands to be re-executed by the string new.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(f c\) :
FCEDIT This variable, when expanded by the shell, shall determine the default value for the -e editor option's editor option-argument. If FCEDIT is null or unset, ed shall be used as the editor.
HISTFILE Determine a pathname naming a command history file. If the HISTFILE variable is not set, the shell may attempt to access or create a file .sh_history in the directory referred to by the HOME environment variable. If the shell cannot obtain both read and write access to, or create, the history file, it shall use an unspecified mechanism that allows the history to operate properly. (References to history "file" in this section shall be understood to mean this unspecified mechanism in such cases.) An implementation may choose to access this variable only when initializing the history file; this initialization shall occur when \(f c\) or sh first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the ENV variable, or implementation-defined system start-up files. In some historical shells, the history file is initialized just after the \(E N V\) file has been processed. Therefore, it is implementation-defined whether changes made to HISTFILE after the history file has been initialized are effective. Implementations may choose to disable the history list mechanism for users with appropriate privileges who do not set HISTFILE; the specific circumstances under which this occurs are implementation-defined. If more than one instance of the shell is using the same history file, it is unspecified how updates to the history file from those shells interact. As entries are deleted from the history file, they shall be deleted oldest first. It is unspecified when history file entries are physically removed from the history file.
HISTSIZE Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 shall be used. The maximum number of commands in the history list is unspecified, but shall be at least 128. An implementation may choose to access this variable only when initializing the history file, as described under HISTFILE. Therefore, it is unspecified whether changes made to HISTSIZE after the history file has been initialized are effective.
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

When the -1 option is used to list commands, the format of each command in the list shall be as follows:
```

"%d\t%s\n", <line number>, <command>

```

If both the \(\mathbf{- l}\) and \(\mathbf{- n}\) options are specified, the format of each command shall be:
"\t\%s\n", <command>
If the <command> consists of more than one line, the lines after the first shall be displayed as:
" \(\backslash \mathrm{t} \% \mathrm{~s} \backslash \mathrm{n}\) ", <continued-command>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion of the listing.
\(>0\) An error occurred.
Otherwise, the exit status shall be that of the commands executed by \(f c\).

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

Since editors sometimes use file descriptors as integral parts of their editing, redirecting their file descriptors as part of the \(f c\) command can produce unexpected results. For example, if \(v i\) is the FCEDIT editor, the command:
fc -s | more
does not work correctly on many systems.
Users on windowing systems may want to have separate history files for each window by setting HISTFILE as follows:
HISTFILE=\$HOME/.sh_hist\$\$

\section*{EXAMPLES}

None.
RATIONALE
This utility is based on the \(f c\) built-in of the KornShell.
An early proposal specified the \(-\mathbf{e}\) option as \([-\mathbf{e}\) editor \([\) old \(=\) new \(]\) ], which is not historical practice. Historical practice in \(f c\) of either [-e editor] or [-e \(-[\) old \(=\) new \(]]\) is acceptable, but not both together. To clarify this, a new option -s was introduced replacing the [-e-]. This resolves the conflict and makes fc conform to the Utility Syntax Guidelines.

HISTFILE Some implementations of the KornShell check for the superuser and do not create a history file unless HISTFILE is set. This is done primarily to avoid creating unlinked files in the root file system when logging in during single-user mode. HISTFILE must be set for the superuser to have history.

HISTSIZE Needed to limit the size of history files. It is the intent of the standard developers that when two shells share the same history file, commands that are entered in one shell shall be accessible by the other shell. Because of the difficulties of synchronization over a network, the exact nature of the interaction is unspecified.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the settings the user has for HISTFILE and HISTSIZE. For example, function definition commands are recorded in the history file. If the system administrator includes function definitions in some system start-up file called before the \(E N V\) file, the history file is initialized before the user can influence its characteristics. In some historical shells, the history file is initialized just after the ENV file has been processed. Because of these situations, the text requires the initialization process to be implementation-defined.
Consideration was given to omitting the \(f c\) utility in favor of the command line editing feature in sh. For example, in vi editing mode, typing "<ESC> v" is equivalent to:

\section*{EDITOR=vi fc}

However, the \(f c\) utility allows the user the flexibility to edit multiple commands simultaneously (such as \(f c 1020\) ) and to use editors other than those supported by sh for command line editing.

In the KornShell, the alias \(\mathbf{r}\) ("re-do") is preset to \(f_{c}-\mathbf{e}-\) (equivalent to the POSIX \(f_{c}-\mathbf{s}\) ). This is probably an easier command name to remember than \(f_{c}\) ("fix command"), but it does not meet the Utility Syntax Guidelines. Renaming fc to hist or redo was considered, but since this description closely matches historical KornShell practice already, such a renaming was seen as gratuitous. Users are free to create aliases whenever odd historical names such as \(f c, a w k\), cat, grep, or yacc are standardized by POSIX.
Command numbers have no ordering effects; they are like serial numbers. The \(-\mathbf{r}\) option and -number operand address the sequence of command execution, regardless of serial numbers. So, for example, if the command number wrapped back to 1 at some arbitrary point, there would be no ambiguity associated with traversing the wrap point. For example, if the command history were:
```

32766: echo 1
32767: echo 2
1: echo 3

```
the number -2 refers to command 32767 because it is the second previous command, regardless of serial number.

\section*{FUTURE DIRECTIONS}

None.

sh

\section*{CHANGE HISTORY}

First released in Issue 4.
Issue 5
The FUTURE DIRECTIONS section is added.

\section*{Issue 6}

This utility is marked as part of the User Portability Utilities option.
In the ENVIRONMENT VARIABLES section, the text "user's home directory" is updated to "directory referred to by the HOME environment variable".

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

\section*{NAME}
fg - run jobs in the foreground

\section*{SYNOPSIS}

UP fg [job_id]

\section*{DESCRIPTION}

If job control is enabled (see the description of set \(-\mathbf{m}\) ), the \(f g\) utility shall move a background job from the current environment (see Section 2.12 (on page 61)) into the foreground.
Using \(f g\) to place a job into the foreground shall remove its process ID from the list of those "known in the current shell execution environment"; see Section 2.9.3.1 (on page 50).

\section*{OPTIONS}

None.
OPERANDS
The following operand shall be supported:
job_id Specify the job to be run as a foreground job. If no job_id operand is given, the job_id for the job that was most recently suspended, placed in the background, or run as a background job shall be used. The format of job_id is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(f g\) :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L \quad\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The \(f g\) utility shall write the command line of the job to standard output in the following format:
"\%s n ", <command>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

\section*{None.}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

If job control is disabled, the \(f g\) utility shall exit with an error and no job shall be placed in the foreground.

\section*{APPLICATION USAGE}

The \(f g\) utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for \(b g\). For this reason, \(f g\) is generally implemented as a shell regular built-in.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The extensions to the shell specified in this volume of IEEE Std 1003.1-200x have mostly been based on features provided by the KornShell. The job control features provided by bg, fg, and jobs are also based on the KornShell. The standard developers examined the characteristics of the \(C\) shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell Versions were selected for this volume of IEEE Std 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).

\section*{FUTURE DIRECTIONS}

None.

Section 2.9.3.1 (on page 50), Section 2.12 (on page 61), bg, kill, jobs, wait

\section*{CHANGE HISTORY}

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
The JC marking is removed from the SYNOPSIS since job control is mandatory is this issue.

\section*{NAME}
file - determine file type

\section*{SYNOPSIS}
```

file [-dh] [-M file] [-m file] file...
file -i [-h] file...

```

\section*{DESCRIPTION}

The file utility shall perform a series of tests in sequence on each specified file in an attempt to classify it:
1. If file does not exist, cannot be read, or its file status could not be determined, the output shall indicate that the file was processed, but that its type could not be determined.
2. If the file is not a regular file, its file type shall be identified. The file types directory, FIFO, socket, block special, and character special shall be identified as such. Other implementation-defined file types may also be identified. If file is a symbolic link, by default the link shall be resolved and file shall test the type of file referenced by the symbolic link. (See the \(-\mathbf{h}\) and -i options below.)
3. If the length of file is zero, it shall be identified as an empty file.
4. The file utility shall examine an initial segment of file and shall make a guess at identifying its contents based on position-sensitive tests. (The answer is not guaranteed to be correct; see the \(-\mathbf{d},-\mathbf{M}\), and \(-\mathbf{m}\) options below.)
5. The file utility shall examine file and make a guess at identifying its contents based on context-sensitive default system tests. (The answer is not guaranteed to be correct.)
6. The file shall be identified as a data file.

If file does not exist, cannot be read, or its file status could not be determined, the output shall indicate that the file was processed, but that its type could not be determined.

If file is a symbolic link, by default the link shall be resolved and file shall test the type of file referenced by the symbolic link.

\section*{OPTIONS}

The file utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the \(-\mathbf{m},-\mathbf{d}\), and \(-\mathbf{M}\) options shall be significant.
The following options shall be supported by the implementation:
-d Apply any position-sensitive default system tests and context-sensitive default system tests to the file. This is the default if no - \(\mathbf{M}\) or \(-\mathbf{m}\) option is specified.
-h When a symbolic link is encountered, identify the file as a symbolic link. If \(\mathbf{- h}\) is not specified and file is a symbolic link that refers to a nonexistent file, file shall identify the file as a symbolic link, as if -h had been specified.
-i If a file is a regular file, do not attempt to classify the type of the file further, but identify the file as specified in the STDOUT section.
-M file Specify the name of a file containing position-sensitive tests that shall be applied to a file in order to classify it (see the EXTENDED DESCRIPTION). No positionsensitive default system tests nor context-sensitive default system tests shall be applied unless the -d option is also specified.
-m file Specify the name of a file containing position-sensitive tests that shall be applied to a file in order to classify it (see the EXTENDED DESCRIPTION).
If the \(-\mathbf{m}\) option is specified without specifying the \(-\mathbf{d}\) option or the \(-\mathbf{M}\) option, positionsensitive default system tests shall be applied after the position-sensitive tests specified by the \(-\mathbf{m}\) option. If the \(-\mathbf{M}\) option is specified with the \(-\mathbf{d}\) option, the \(-\mathbf{m}\) option, or both, or the \(-\mathbf{m}\) option is specified with the -d option, the concatenation of the position-sensitive tests specified by these options shall be applied in the order specified by the appearance of these options. If a \(\mathbf{- M}\) or \(\mathbf{- m}\) file option-argument is - , the results are unspecified.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a file to be tested.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

The file can be any file type.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of file:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

In the POSIX locale, the following format shall be used to identify each operand, file specified:
"\%s: \%s\n", <file>, <type>
The values for <type> are unspecified, except that in the POSIX locale, if file is identified as one of the types listed in the following table, <type> shall contain (but is not limited to) the corresponding string, unless the file is identified by a position-sensitive test specified by a \(-\mathbf{M}\) or \(-\mathbf{m}\) option. Each space shown in the strings shall be exactly one <space>.

Table 4-8 File Utility Output Strings
\begin{tabular}{|l|l|l|}
\hline \multicolumn{1}{|c|}{ If file is: } & <type> shall contain the string: & Notes \\
\hline Nonexistent & cannot open & \\
Block special & block special & 1 \\
Character special & character special & 1 \\
Directory & directory & 1 \\
FIFO & fifo & 1 \\
Socket & socket & 1 \\
Symbolic link & symbolic link to & 1 \\
Regular file & regular file & 1,2 \\
Empty regular file & empty & 3 \\
Regular file that cannot be read & cannot open & 3 \\
Executable binary & executable & \(3,4,6\) \\
ar archive library (see ar) & archive & \(3,4,6\) \\
Extended cpio format (see pax) & cpio archive & \(3,4,6\) \\
Extended tar format (see ustar in pax) & tar archive & \(3,4,6\) \\
Shell script & commands text & \(3,5,6\) \\
C-language source & c program text \\
FORTRAN source & fortran program text & \(3,5,6\) \\
Regular file whose type cannot be determined & data & \(3,5,6\) \\
\hline
\end{tabular}

\section*{Notes:}
1. This is a file type test.
2. This test is applied only if the \(-\mathbf{i}\) option is specified.
3. This test is applied only if the -i option is not specified.
4. This is a position-sensitive default system test.
5. This is a context-sensitive default system test.
6. Position-sensitive default system tests and context-sensitive default system tests are not applied if the \(-\mathbf{M}\) option is specified unless the \(-\mathbf{d}\) option is also specified.

In the POSIX locale, if file is identified as a symbolic link (see the \(-\mathbf{h}\) option), the following alternative output format shall be used:
"\%s: \%s \%s \(\backslash n ",<t i l e>,<t y p e>,<c o n t e n t s\) of link>"
If the file named by the file operand does not exist, cannot be read, or the type of the file named by the file operand cannot be determined, this shall not be considered an error that affects the exit status.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

A file specified as an option-argument to the - \(\mathbf{m}\) or \(\mathbf{- M}\) options shall contain one positionsensitive test per line, which shall be applied to the file. If the test succeeds, the message field of the line shall be printed and no further tests shall be applied, with the exception that tests on immediately following lines beginning with a single ' \(>\) ' character shall be applied.

Each line shall be composed of the following four <tab>-separated fields. (Implementations may allow any combination of one or more white space characters other than <newline> to act as field separators.)
offset An unsigned number (optionally preceded by a single \({ }^{\prime}>{ }^{\prime}\) character) specifying the offset, in bytes, of the value in the file that is to be compared against the value field of the line. If the file is shorter than the specified offset, the test shall fail.

If the offset begins with the character \({ }^{\prime}>\) ', the test contained in the line shall not be applied to the file unless the test on the last line for which the offset did not begin with a ' >' was successful. By default, the offset shall be interpreted as an unsigned decimal number. With a leading \(0 x\) or \(0 X\), the offset shall be interpreted as a hexadecimal number; otherwise, with a leading 0 , the offset shall be interpreted as an octal number.

The type of the value in the file to be tested. The type shall consist of the type specification characters \(d, s\), and \(u\), specifying signed decimal, string, and unsigned decimal, respectively.
The type string shall be interpreted as the bytes from the file starting at the specified offset and including the same number of bytes specified by the value field. If insufficient bytes remain in the file past the offset to match the value field, the test shall fail.

The type specification characters \(d\) and \(u\) can be followed by an optional unsigned decimal integer that specifies the number of bytes represented by the type. The type specification characters \(d\) and \(u\) can be followed by an optional \(C, S, I\), or \(L\), indicating that the value is of type char, short, int, or long, respectively.
The default number of bytes represented by the type specifiers \(d, f\), and \(u\) shall correspond to their respective C-language types as follows. If the system claims conformance to the C-Language Development Utilities option, those specifiers shall correspond to the default sizes used in the c99 utility. Otherwise, the default sizes shall be implementation-defined.

For the type specifier characters \(d\) and \(u\), the default number of bytes shall correspond to the size of a basic integer type of the implementation. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the Clanguage types char, short, int, or long. These numbers can also be specified by an application as the characters \(C, S, I\), and \(L\), respectively. The byte order used when interpreting numeric values is implementation-defined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.
All type specifiers, except for \(s\), can be followed by a mask specifier of the form \&number. The mask value shall be AND'ed with the value of the input file before the comparison with the value field of the line is made. By default, the mask shall be interpreted as an unsigned decimal number. With a leading 0x or 0X, the mask shall be interpreted as an unsigned hexadecimal number; otherwise, with a leading 0 , the mask shall be interpreted as an unsigned octal number.

The strings byte, short, long, and string shall also be supported as type fields, being interpreted as \(\mathrm{dC}, \mathrm{dS}, \mathrm{dL}\), and s , respectively.
value \(\quad\) The value to be compared with the value from the file.
If the specifier from the type field is \(s\) or string, then interpret the value as a string. Otherwise, interpret it as a number. If the value is a string, then the test shall succeed only when a string value exactly matches the bytes from the file.

\section*{APPLICATION USAGE}

The file utility can only be required to guess at many of the file types because only exhaustive testing can determine some types with certainty. For example, binary data on some implementations might match the initial segment of an executable or a tar archive.

Note that the table indicates that the output contains the stated string. Systems may add text before or after the string. For executables, as an example, the machine architecture and various facts about how the file was link-edited may be included. Note also that on systems that recognize shell script files starting with "\#!" as executable files, these may be identified as executable binary files rather than as shell scripts.

\section*{EXAMPLES}

Determine whether an argument is a binary executable file:
```

file "\$1" | grep -Fq executable \&\&
printf "\%s is executable. \n" "\$1"

```

\section*{RATIONALE}

The -f option was omitted because the same effect can (and should) be obtained using the xargs utility.

Historical versions of the file utility attempt to identify the following types of files: symbolic link, directory, character special, block special, socket, tar archive, cpio archive, SCCS archive, archive library, empty, compress output, pack output, binary data, C source, FORTRAN source, assembler source, nroff/troff/eqn/tbl source troff output, shell script, C shell script, English text, ASCII text, various executables, APL workspace, compiled terminfo entries, and CURSES screen images. Only those types that are reasonably well specified in POSIX or are directly related to POSIX utilities are listed in the table.

Historical systems have used a "magic file" named /etc/magic to help identify file types. Because it is generally useful for users and scripts to be able to identify special file types, the -m flag and a portable format for user-created magic files has been specified. No requirement is made that an implementation of file use this method of identifying files, only that users be permitted to add their own classifying tests.

In addition, three options have been added to historical practice. The \(-\mathbf{d}\) flag has been added to permit users to cause their tests to follow any default system tests. The \(\mathbf{- i}\) flag has been added to permit users to test portably for regular files in shell scripts. The \(\mathbf{-} \mathbf{M}\) flag has been added to permit users to ignore any default system tests.

The IEEE Std 1003.1-200x description of default system tests and the interaction between the \(-\mathbf{d}\), \(-\mathbf{M}\), and \(-\mathbf{m}\) options did not clearly indicate that there were two types of "default system tests". The "position-sensitive tests" determine file types by looking for certain string or binary values at specific offsets in the file being examined. These position-sensitive tests were implemented in historical systems using the magic file described above. Some of these tests are now built into the file utility itself on some implementations so the output can provide more detail than can be provided by magic files. For example, a magic file can easily identify a core file on most implementations, but cannot name the program file that dropped the core. A magic file could produce output such as:
/home/dwc/core: ELF 32-bit MSB core file SPARC Version 1
but by building the test into the file utility, you could get output such as:
/home/dwc/core: ELF 32-bit MSB core file SPARC Version 1, from 'testprog'
These extended built-in tests are still to be treated as position-sensitive default system tests even if they are not listed in /etc/magic or any other magic file.
The context-sensitive default system tests were always built into the file utility. These tests looked for language constructs in text files trying to identify shell scripts, C, FORTRAN, and
other computer language source files, and even plain text files. With the addition of the \(-\mathbf{m}\) and - \(\mathbf{M}\) options the distinction between position-sensitive and context-sensitive default system tests became important because the order of testing is important. The context-sensitive system default tests should never be applied before any position-sensitive tests even if the -d option is specified before \(\mathbf{a}-\mathbf{m}\) option or \(\mathbf{- M}\) option due to the high probability that the context-sensitive system default tests will incorrectly identify arbitrary text files as text files before position-sensitive tests specified by the \(\mathbf{- m}\) or \(-\mathbf{M}\) option would be applied to give a more accurate identification.

Leaving the meaning of \(-\mathbf{M}-\) and \(\mathbf{- m}\) - unspecified allows an existing prototype of these options to continue to work in a backwards-compatible manner. (In that implementation, \(\mathbf{- M}-\) was roughly equivalent to -d in IEEE Std 1003.1-200x.)

The historical -c option was omitted as not particularly useful to users or portable shell scripts. In addition, a reasonable implementation of the file utility would report any errors found each time the magic file is read.
The historical format of the magic file was the same as that specified by the Rationale in the ISO POSIX-2: 1993 standard for the offset, value, and message fields; however, it used less precise type fields than the format specified by the current normative text. The new type field values are a superset of the historical ones.

The following is an example magic file:

The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

\section*{FUTURE DIRECTIONS}

None.

\section*{CHANGE HISTORY}

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
Options and an EXTENDED DESCRIPTION are added as specified in the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 \#192 and \#178 are applied.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/25 is applied, making major changes to address ambiguities raised in defect reports.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/26 is applied, making it clear in the OPTIONS section that the \(-\mathbf{m}, \mathbf{- d}\), and \(-\mathbf{M}\) options do not comply with Guideline 11 of the Utility Syntax Guidelines.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/10 is applied, clarifying the specification characters.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/11 is applied, allowing application writers to create portable magic files that can match characters in strings, and allowing common extensions found in existing implementations.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/12 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

\section*{Issue 7}

SD5-XCU-ERN-4 is applied, adding further entries in the Notes column in Table 4-8.
The file utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
find - find files

\section*{SYNOPSIS}
```

find [-H|-L] path... [operand_expression...]

```

\section*{DESCRIPTION}

The find utility shall recursively descend the directory hierarchy from each file specified by path, evaluating a Boolean expression composed of the primaries described in the OPERANDS section for each file encountered.
The find utility shall be able to descend to arbitrary depths in a file hierarchy and shall not fail due to path length limitations (unless a path operand specified by the application exceeds \{PATH_MAX\} requirements).
The find utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, find shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

\section*{OPTIONS}

The find utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-H Cause the file information and file type evaluated for each symbolic link encountered on the command line to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself. File information for all symbolic links not on the command line shall be that of the link itself.
-L Cause the file information and file type evaluated for each symbolic link to be those of the file referenced by the link, and not the link itself. If the referenced file does not exist, the file information and type shall be for the link itself.
Specifying more than one of the mutually-exclusive options -H and -L shall not be considered an error. The last option specified shall determine the behavior of the utility.

\section*{OPERANDS}

The following operands shall be supported:
The path operand is a pathname of a starting point in the directory hierarchy.
The first operand that starts with \(\mathrm{a}^{\prime} \mathrm{Z}^{\prime}\), or is a ' !' or a ' \(('\), and all subsequent arguments shall be interpreted as an expression made up of the following primaries and operators. In the descriptions, wherever \(n\) is used as a primary argument, it shall be interpreted as a decimal integer optionally preceded by a plus ( \({ }^{\prime}+\prime\) ) or minus ( \(\left(^{\prime}\right.\) ) sign, as follows:
```

+n More than n.

```
\(n\) Exactly \(n\).
\(-n\) Less than \(n\).
The following primaries shall be supported:
-name pattern
The primary shall evaluate as true if the basename of the filename being examined matches pattern using the pattern matching notation described in Section 2.13 (on
page 62).
-nouser The primary shall evaluate as true if the file belongs to a user ID for which the getpwuid() function defined in the System Interfaces volume of IEEE Std 1003.1-200x (or equivalent) returns NULL.
-nogroup The primary shall evaluate as true if the file belongs to a group ID for which the getgrgid() function defined in the System Interfaces volume of IEEE Std 1003.1-200x (or equivalent) returns NULL.
-xdev The primary shall always evaluate as true; it shall cause find not to continue descending past directories that have a different device ID (st_dev, see the stat () function defined in the System Interfaces volume of IEEE Std 1003.1-200x). If any \(-\mathbf{x d e v}\) primary is specified, it shall apply to the entire expression even if the \(-\mathbf{x d e v}\) primary would not normally be evaluated.
-prune The primary shall always evaluate as true; it shall cause find not to descend the current pathname if it is a directory. If the -depth primary is specified, the -prune primary shall have no effect.
-perm [-]mode
The mode argument is used to represent file mode bits. It shall be identical in format to the symbolic_mode operand described in chmod, and shall be interpreted as follows. To start, a template shall be assumed with all file mode bits cleared. An op symbol of \({ }^{\prime}+{ }^{\prime}\) shall set the appropriate mode bits in the template; ' -' shall clear the appropriate bits; \({ }^{\prime}=\prime\) shall set the appropriate mode bits, without regard to the contents of the file mode creation mask of the process. The op symbol of ' -' cannot be the first character of mode; this avoids ambiguity with the optional leading hyphen. Since the initial mode is all bits off, there are not any symbolic modes that need to use \({ }^{\prime}-^{\prime}\) as the first character.
If the hyphen is omitted, the primary shall evaluate as true when the file permission bits exactly match the value of the resulting template.
Otherwise, if mode is prefixed by a hyphen, the primary shall evaluate as true if at least all the bits in the resulting template are set in the file permission bits.
-perm I-lonum
If the hyphen is omitted, the primary shall evaluate as true when the file mode bits exactly match the value of the octal number onum (see the description of the octal mode in chmod). Otherwise, if onum is prefixed by a hyphen, the primary shall evaluate as true if at least all of the bits specified in onum are set. In both cases, the behavior is unspecified when onum exceedes 07777.
-type \(c \quad\) The primary shall evaluate as true if the type of the file is \(c\), where \(c\) is ' \(b^{\prime},{ }^{\prime} c^{\prime}\) ', ' \(d^{\prime}, ' l^{\prime}, ~ ' p ', ~ f '\), or ' \(s^{\prime}\) for block special file, character special file, directory, symbolic link, FIFO, regular file, or socket, respectively.
-links \(n \quad\) The primary shall evaluate as true if the file has \(n\) links.
-user uname The primary shall evaluate as true if the file belongs to the user uname. If uname is a decimal integer and the getpwnam() (or equivalent) function does not return a valid user name, uname shall be interpreted as a user ID.
-group gname
The primary shall evaluate as true if the file belongs to the group gname. If gname is a decimal integer and the getgrnam() (or equivalent) function does not return a valid group name, gname shall be interpreted as a group ID.
```

-size $n[\mathbf{c}] \quad$ The primary shall evaluate as true if the file size in bytes, divided by 512 and rounded up to the next integer, is $n$. If $n$ is followed by the character ' $c$ ', the size shall be in bytes.
-atime $n \quad$ The primary shall evaluate as true if the file access time subtracted from the initialization time, divided by 86400 (with any remainder discarded), is $n$.
-ctime $n$ The primary shall evaluate as true if the time of last change of file status information subtracted from the initialization time, divided by 86400 (with any remainder discarded), is $n$.
-mtime $n \quad$ The primary shall evaluate as true if the file modification time subtracted from the initialization time, divided by 86400 (with any remainder discarded), is $n$.
-exec utility_name [argument . . .];
-exec utility_name [argument ...] \{\} +
The end of the primary expression shall be punctuated by a semicolon or by a plus sign. Only a plus sign that follows an argument containing the two characters " $\}$ " shall punctuate the end of the primary expression. Other uses of the plus sign shall not be treated as special.

If the primary expression is punctuated by a semicolon, the utility utility_name shall be invoked once for each pathname and the primary shall evaluate as true if the utility returns a zero value as exit status. A utility_name or argument containing only the two characters " $\}$ " shall be replaced by the current pathname.
If the primary expression is punctuated by a plus sign, the primary shall always evaluate as true, and the pathnames for which the primary is evaluated shall be aggregated into sets. The utility utility_name shall be invoked once for each set of aggregated pathnames. Each invocation shall begin after the last pathname in the set is aggregated, and shall be completed before the find utility exits and before the first pathname in the next set (if any) is aggregated for this primary, but it is otherwise unspecified whether the invocation occurs before, during, or after the evaluations of other primaries. If any invocation returns a non-zero value as exit status, the find utility shall return a non-zero exit status. An argument containing only the two characters " $\}$ " shall be replaced by the set of aggregated pathnames, with each pathname passed as a separate argument to the invoked utility in the same order that it was aggregated. The size of any set of two or more pathnames shall be limited such that execution of the utility does not cause the system's \{ARG_MAX\} limit to be exceeded. If more than one argument containing only the two characters " $\}$ " is present, the behavior is unspecified.
If a utility_name or argument string contains the two characters " $\}$ ", but not just the two characters " $\}$ ", it is implementation-defined whether find replaces those two characters or uses the string without change. The current directory for the invocation of utility_name shall be the same as the current directory when the find utility was started. If the utility_name names any of the special built-in utilities (see Section 2.14 (on page 64)), the results are undefined.
-ok utility_name [argument ...];
The -ok primary shall be equivalent to -exec, except that the use of a plus sign to punctuate the end of the primary expression need not be supported, and find shall request affirmation of the invocation of utility_name using the current file as an argument by writing to standard error as described in the STDERR section. If the response on standard input is affirmative, the utility shall be invoked. Otherwise, the command shall not be invoked and the value of the -ok operand shall be false.
-print The primary shall always evaluate as true; it shall cause the current pathname to be written to standard output.
-newer file The primary shall evaluate as true if the modification time of the current file is more recent than the modification time of the file named by the pathname file.
-depth The primary shall always evaluate as true; it shall cause descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. If a -depth primary is not specified, all entries in a directory shall be acted on after the directory itself. If any -depth primary is specified, it shall apply to the entire expression even if the -depth primary would not normally be evaluated.

The primaries can be combined using the following operators (in order of decreasing precedence):
( expression ) True if expression is true.
! expression Negation of a primary; the unary NOT operator. expression $[-\mathbf{a}]$ expression

Conjunction of primaries; the AND operator is implied by the juxtaposition of two primaries or made explicit by the optional -a operator. The second expression shall not be evaluated if the first expression is false.
expression -o expression
Alternation of primaries; the OR operator. The second expression shall not be evaluated if the first expression is true.
If no expression is present, -print shall be used as the expression. Otherwise, if the given expression does not contain any of the primaries -exec, -ok, or -print, the given expression shall be effectively replaced by:
( given_expression) -print
The -user, -group, and -newer primaries each shall evaluate their respective arguments only once.

## STDIN

If the -ok primary is used, the response shall be read from the standard input. An entire line shall be read as the response. Otherwise, the standard input shall not be used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of find:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L \quad$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements used in the pattern matching notation for the $-\mathbf{n}$ option and in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.

LC_CTYPE This variable determines the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments), the behavior of character classes within the pattern matching notation used for the - $\mathbf{n}$ option, and the behavior of character classes within regular expressions used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the location of the utility_name for the -exec and -ok primaries, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The -print primary shall cause the current pathnames to be written to standard output. The format shall be:
"\%s\n", <path>
STDERR
The -ok primary shall write a prompt to standard error containing at least the utility_name to be invoked and the current pathname. In the POSIX locale, the last non-<blank> in the prompt shall be ' ?'. The exact format used is unspecified.
Otherwise, the standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.
EXIT STATUS
The following exit values shall be returned:
0 All path operands were traversed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

When used in operands, pattern matching notation, semicolons, opening parentheses, and closing parentheses are special to the shell and must be quoted (see Section 2.2 (on page 30)).

The bit that is traditionally used for sticky (historically 01000) is specified in the -perm primary using the octal number argument form. Since this bit is not defined by this volume of IEEE Std 1003.1-200x, applications must not assume that it actually refers to the traditional sticky bit.

## EXAMPLES

1. The following commands are equivalent:
find .
find . -print
They both write out the entire directory hierarchy from the current directory.
2. The following command:
find / <br>( -name tmp -o -name '*.xx' <br>) -atime +7 -exec rm \{\} \;
removes all files named $\mathbf{t m p}$ or ending in. $\boldsymbol{x x}$ that have not been accessed for seven or more 24-hour periods.
3. The following command:
find . -perm -o+w, +s
prints (-print is assumed) the names of all files in or below the current directory, with all of the file permission bits S_ISUID, S_ISGID, and S_IWOTH set.
4. The following command:
find . -name SCCS -prune -o -print
recursively prints pathnames of all files in the current directory and below, but skips directories named SCCS and files in them.
5. The following command:
find . -print -name SCCS -prune
behaves as in the previous example, but prints the names of the SCCS directories.
6. The following command is roughly equivalent to the $\mathbf{- n t}$ extension to test:
```
if [ -n "$(find file1 -prune -newer file2)" ]; then
    printf %s\\n "file1 is newer than file2"
fi
```

7. The descriptions of -atime, -ctime, and -mtime use the terminology $n$ " 86400 second periods (days)". For example, a file accessed at $23: 59$ is selected by:
find. -atime -1 -print
at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24 -hour calculation.
8. The following command:
```
find . ! -name . -prune -name '*.old' -exec \
    sh -c 'mv "$@" ../old/' sh {} +
```

performs the same task as:
mv ./*.old ./.*.old ../old/
while avoiding an "Argument list too long" error if there are a large number of files ending with .old (and avoiding "No such file or directory" errors if no files match . ${ }^{*}$.old or . I. ${ }^{*}$.old).
The alternative:
find . ! -name . -prune -name '*.old' -exec mv \{\} ../old/ \;
is less efficient if there are many files to move because it executes one $m v$ command per

## RATIONALE

The -a operator was retained as an optional operator for compatibility with historical shell scripts, even though it is redundant with expression concatenation.

The descriptions of the ${ }^{\prime}-^{\prime}$ modifier on the mode and onum arguments to the - perm primary agree with historical practice on BSD and System V implementations. System V and BSD documentation both describe it in terms of checking additional bits; in fact, it uses the same bits, but checks for having at least all of the matching bits set instead of having exactly the matching bits set.

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because:

- Implementations may desire more descriptive prompts than those used on historical implementations.
- Since the historical prompt strings do not terminate with <newline>s, there is no portable way for another program to interact with the prompts of this utility via pipes.

Therefore, an application using this prompting option relies on the system to provide the most suitable dialog directly with the user, based on the general guidelines specified.

The -name file operand was changed to use the shell pattern matching notation so that find is consistent with other utilities using pattern matching.

The -size operand refers to the size of a file, rather than the number of blocks it may occupy in the file system. The intent is that the st_size field defined in the System Interfaces volume of IEEE Std 1003.1-200x should be used, not the st_blocks found in historical implementations. There are at least two reasons for this:

1. In both System V and BSD, find only uses st size in size calculations for the operands specified by this volume of IEEE Std 1003.1-200x. (BSD uses st_blocks only when processing the -1s primary.)
2. Users usually think of file size in terms of bytes, which is also the unit used by the $l$ s utility for the output from the -1 option. (In both System V and BSD, $l$ s uses st_size for the -1 option size field and uses st_blocks for the $l s-s$ calculations. This volume of IEEE Std 1003.1-200x does not specify $l s-s$.)

The descriptions of -atime, -ctime, and -mtime were changed from the SVID description of $n$ "days" to $n$ being the result of the integer division of the time difference in seconds by 86400. The description is also different in terms of the exact timeframe for the $n$ case (versus the $+n$ or $-n$ ), but it matches all known historical implementations. It refers to one 86400 second period in the past, not any time from the beginning of that period to the current time. For example, -atime 2 is true if the file was accessed any time in the period from 72 hours to 48 hours ago.
Historical implementations do not modify " \{ \}" when it appears as a substring of an -exec or -ok utility_name or argument string. There have been numerous user requests for this extension, so this volume of IEEE Std 1003.1-200x allows the desired behavior. At least one recent implementation does support this feature, but encountered several problems in managing memory allocation and dealing with multiple occurrences of " $\}$ " in a string while it was being developed, so it is not yet required behavior.

Assuming the presence of -print was added to correct a historical pitfall that plagues novice users, it is entirely upwards-compatible from the historical System V find utility. In its simplest form (find directory), it could be confused with the historical BSD fast find. The BSD developers agreed that adding -print as a default expression was the correct decision and have added the fast find functionality within a new utility called locate.

Historically, the $-\mathbf{L}$ option was implemented using the primary -follow. The $-\mathbf{H}$ and $-\mathbf{L}$ options were added for two reasons. First, they offer a finer granularity of control and consistency with other programs that walk file hierarchies. Second, the -follow primary always evaluated to true. As they were historically really global variables that took effect before the traversal began, some valid expressions had unexpected results. An example is the expression -print -o -follow. Because - print always evaluates to true, the standard order of evaluation implies that -follow would never be evaluated. This was never the case. Historical practice for the -follow primary, however, is not consistent. Some implementations always follow symbolic links on the command line whether -follow is specified or not. Others follow symbolic links on the command line only if -follow is specified. Both behaviors are provided by the $-\mathbf{H}$ and $-\mathbf{L}$ options, but scripts using the current -follow primary would be broken if the -follow option is specified to work either way.

Since the -L option resolves all symbolic links and the -type $l$ primary is true for symbolic links that still exist after symbolic links have been resolved, the command:

```
find -L . -type l
```

prints a list of symbolic links reachable from the current directory that do not resolve to accessible files.

A feature of SVR4's find utility was the -exec primary's + terminator. This allowed filenames containing special characters (especially <newline>s) to be grouped together without the problems that occur if such filenames are piped to xargs. Other implementations have added other ways to get around this problem, notably a -print0 primary that wrote filenames with a null byte terminator. This was considered here, but not adopted. Using a null terminator meant that any utility that was going to process find's - print0 output had to add a new option to parse the null terminators it would now be reading.
The "-ехес ... $\}+$ " syntax adopted was a result of IEEE PASC Interpretation 1003.2 \#210. It should be noted that this is an incompatible change to the ISO/IEC 9899: 1999 standard. For example, the following command prints all files with $a^{\prime}-^{\prime}$ after their name if they are regular files, and a ${ }^{\prime}+{ }^{\prime}$ otherwise:
find / -type f -exec echo \{\}-(;' -o -exec echo \{\} + ';'
The change invalidates usage like this. Even though the previous standard stated that this usage would work, in practice many did not support it and the standard developers felt it better to now state that this was not allowable.

## FUTURE DIRECTIONS

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The-perm [-]onum primary is supported.

The find utility is aligned with the IEEE P1003.2b draft standard, to include processing of symbolic links and changes to the description of the atime, ctime, and mtime operands.

IEEE PASC Interpretation 1003.2 \#210 is applied, extending the -exec operand.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/13 is applied, updating the RATIONALE section to be consistent with the normative text.

Issue 7
SD5-XCU-ERN-48 is applied, clarifying the -L option in the case that the referenced file does not exist.

SD5-XCU-ERN-89 is applied, updating the OPERANDS section.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-117 is applied, clarifying the -perm operand.
SD5-XCU-ERN-122 is applied, adding a new EXAMPLE.

## NAME

fold - filter for folding lines
SYNOPSIS

```
fold [-bs] [-w width] [file...]
```

## DESCRIPTION

The fold utility is a filter that shall fold lines from its input files, breaking the lines to have a maximum of width column positions (or bytes, if the -b option is specified). Lines shall be broken by the insertion of a <newline> such that each output line (referred to later in this section as a segment) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line shall not be broken in the middle of a character. The behavior is undefined if width is less than the number of columns any single character in the input would occupy.
If the <carriage-return>s, <backspace>s, or <tab>s are encountered in the input, and the -b option is not specified, they shall be treated specially:
<backspace> The current count of line width shall be decremented by one, although the count never shall become negative. The fold utility shall not insert a <newline> immediately before or after any <backspace>.
<carriage-return>
The current count of line width shall be set to zero. The fold utility shall not insert a <newline> immediately before or after any <carriage-return>.
<tab> Each <tab> encountered shall advance the column position pointer to the next tab stop. Tab stops shall be at each column position $n$ such that $n$ modulo 8 equals 1 .

## OPTIONS

The fold utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-b Count width in bytes rather than column positions.
-s If a segment of a line contains a <blank> within the first width column positions (or bytes), break the line after the last such <blank> meeting the width constraints. If there is no <blank> meeting the requirements, the -s option shall have no effect for that output segment of the input line.
-w width Specify the maximum line length, in column positions (or bytes if $-\mathbf{b}$ is specified). The results are unspecified if width is not a positive decimal number. The default value shall be 80 .

## OPERANDS

The following operand shall be supported:
file A pathname of a text file to be folded. If no file operands are specified, the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

If the -b option is specified, the input files shall be text files except that the lines are not limited to \{LINE_MAX\} bytes in length. If the -b option is not specified, the input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of fold:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and for the determination of the width in column positions each character would occupy on a constant-width font output device.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.
STDOUT
The standard output shall be a file containing a sequence of characters whose order shall be preserved from the input files, possibly with inserted <newline>s.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were processed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The cut and fold utilities can be used to create text files out of files with arbitrary line lengths. The cut utility should be used when the number of lines (or records) needs to remain constant. The fold utility should be used when the contents of long lines need to be kept contiguous.
The fold utility is frequently used to send text files to printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

## EXAMPLES

An example invocation that submits a file of possibly long lines to the printer (under the assumption that the user knows the line width of the printer to be assigned by $l p$ ):

```
fold -w 132 bigfile | lp
```

## RATIONALE

Although terminal input in canonical processing mode requires the erase character (frequently set to <backspace>) to erase the previous character (not byte or column position), terminal output is not buffered and is extremely difficult, if not impossible, to parse correctly; the interpretation depends entirely on the physical device that actually displays/prints/stores the output. In all known internationalized implementations, the utilities producing output for mixed column-width output assume that a <backspace> backs up one column position and outputs enough <backspace>s to return to the start of the character when <backspace> is used to provide local line motions to support underlining and emboldening operations. Since fold without the $-\mathbf{b}$ option is dealing with these same constraints, <backspace> is always treated as backing up one column position rather than backing up one character.
Historical versions of the fold utility assumed 1 byte was one character and occupied one column position when written out. This is no longer always true. Since the most common usage of fold is believed to be folding long lines for output to limited-length output devices, this capability was preserved as the default case. The -b option was added so that applications could fold files with arbitrary length lines into text files that could then be processed by the standard utilities. Note that although the width for the $-\mathbf{b}$ option is in bytes, a line is never split in the middle of a character. (It is unspecified what happens if a width is specified that is too small to hold a single character found in the input followed by a <newline>.)
The tab stops are hardcoded to be every eighth column to meet historical practice. No new method of specifying other tab stops was invented.

## FUTURE DIRECTIONS

None.
SEE ALSO

## CHANGE HISTORY

First released in Issue 4.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

fort77 - FORTRAN compiler (FORTRAN)

## SYNOPSIS

FD fort77 [-c] [-g] [-L directory]... [-O optlevel] [-o outfile] [-s] [-w] operand...

## DESCRIPTION

The fort77 utility is the interface to the FORTRAN compilation system; it shall accept the full FORTRAN-77 language defined by the ANSI X3.9-1978 standard. The system conceptually consists of a compiler and link editor. The files referenced by operands are compiled and linked to produce an executable file. It is unspecified whether the linking occurs entirely within the operation of fort77; some implementations may produce objects that are not fully resolved until the file is executed.

If the -c option is present, for all pathname operands of the form file.f, the files:
\$(basename pathname.f).o
shall be created or overwritten as the result of successful compilation. If the -c option is not specified, it is unspecified whether such .o files are created or deleted for the file.f operands.
If there are no options that prevent link editing (such as -c) and all operands compile and link without error, the resulting executable file shall be written into the file named by the -o option (if present) or to the file a.out. The executable file shall be created as specified in the System Interfaces volume of IEEE Std 1003.1-200x, except that the file permissions shall be set to:
S_IRWXO | S_IRWXG | S_IRWXU
and that the bits specified by the umask of the process shall be cleared.

## OPTIONS

The fort77 utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that:

- The -l library operands have the format of options, but their position within a list of operands affects the order in which libraries are searched.
- The order of specifying the multiple $-\mathbf{L}$ options is significant.
- Conforming applications shall specify each option separately; that is, grouping option letters (for example, -cg ) need not be recognized by all implementations.
The following options shall be supported:
-c Suppress the link-edit phase of the compilation, and do not remove any object files that are produced.
-g Produce symbolic information in the object or executable files; the nature of this information is unspecified, and may be modified by implementation-defined interactions with other options.
-s Produce object or executable files, or both, from which symbolic and other information not required for proper execution using the exec family of functions defined in the System Interfaces volume of IEEE Std 1003.1-200x has been removed (stripped). If both $-\mathbf{g}$ and $-s$ options are present, the action taken is unspecified.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of fort77:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TMPDIR Determine the pathname that should override the default directory for temporary files, if any.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages. If more than one file operand ending in .f (or possibly other unspecified suffixes) is given, for each such file:
"\%s: \n", <file>
may be written to allow identification of the diagnostic message with the appropriate input file.
This utility may produce warning messages about certain conditions that do not warrant returning an error (non-zero) exit value.

## OUTPUT FILES

Object files, listing files, and executable files shall be produced in unspecified formats.

## EXTENDED DESCRIPTION

## Standard Libraries

The fort77 utility shall recognize the following -1 operand for the standard library:
-lf This library contains all functions referenced in the ANSI X3.9-1978 standard. This operand shall not be required to be present to cause a search of this library.

In the absence of options that inhibit invocation of the link editor, such as $-\mathbf{c}$, the fort 77 utility shall cause the equivalent of a $-\mathbf{l} \mathbf{f}$ operand to be passed to the link editor as the last $-\mathbf{l}$ operand, causing it to be searched after all other object files and libraries are loaded.

It is unspecified whether the library libf.a exists as a regular file. The implementation may accept as $\mathbf{- 1}$ operands names of objects that do not exist as regular files.

## External Symbols

The FORTRAN compiler and link editor shall support the significance of external symbols up to a length of at least 31 bytes; case folding is permitted. The action taken upon encountering symbols exceeding the implementation-defined maximum symbol length is unspecified.

The compiler and link editor shall support a minimum of 511 external symbols per source or object file, and a minimum of 4095 external symbols total. A diagnostic message is written to standard output if the implementation-defined limit is exceeded; other actions are unspecified.

## EXIT STATUS

The following exit values shall be returned:
0 Successful compilation or link edit.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

When fort77 encounters a compilation error, it shall write a diagnostic to standard error and continue to compile other source code operands. It shall return a non-zero exit status, but it is implementation-defined whether an object module is created. If the link edit is unsuccessful, a diagnostic message shall be written to standard error, and fort77 shall exit with a non-zero status.

## APPLICATION USAGE <br> None.

## EXAMPLES

The following usage example compiles xyz.f and creates the executable file foo:
fort77 -o foo xyz.f
The following example compiles xyz.f and creates the object file xyz.o.
fort77 -c xyz.f
The following example compiles xyz.f and creates the executable file a.out:
fort $77 \mathrm{xyz} . \mathrm{f}$
The following example compiles xyz.f, links it with b.o, and creates the executable a.out:
fort 77 xyz .f b.o

## RATIONALE

The name of this utility was chosen as fort77 to parallel the renaming of the $C$ compiler. The name f77 was not chosen to avoid problems with historical implementations. The ANSI X3.9-1978 standard was selected as a normative reference because the ISO/IEC version of FORTRAN-77 has been superseded by the ISO/IEC 1539: 1990 standard (Fortran-90).
The file inclusion and symbol definition \#define mechanisms used by the c99 utility were not included in this volume of IEEE Std 1003.1-200x—even though they are commonly implemented-since there is no requirement that the FORTRAN compiler use the $C$ preprocessor.

The -onetrip option was not included in this volume of IEEE Std 1003.1-200x, even though many historical compilers support it, because it is derived from FORTRAN-66; it is an anachronism that should not be perpetuated.

Some implementations produce compilation listings. This aspect of FORTRAN has been left unspecified because there was controversy concerning the various methods proposed for implementing it: a $\mathbf{- V}$ option overlapped with historical vendor practice and a naming convention of creating files with $\mathbf{l} 1$ suffixes collided with historical lex file naming practice.
There is no -I option in this version of this volume of IEEE Std 1003.1-200x to specify a directory
for file inclusion. An INCLUDE directive has been a part of the Fortran-90 discussions, but an interface supporting that standard is not in the current scope.
It is noted that many FORTRAN compilers produce an object module even when compilation errors occur; during a subsequent compilation, the compiler may patch the object module rather than recompiling all the code. Consequently, it is left to the implementor whether or not an object file is created.

A reference to MIL-STD-1753 was removed from an early proposal in response to a request from the POSIX FORTRAN-binding standard developers. It was not the intention of the standard developers to require certification of the FORTRAN compiler, and IEEE Std 1003.9-1992 does not specify the military standard or any special preprocessing requirements. Furthermore, use of that document would have been inappropriate for an international standard.

The specification of optimization has been subject to changes through early proposals. At one time, $\mathbf{- O}$ and $-\mathbf{N}$ were Booleans: optimize and do not optimize (with an unspecified default). Some historical practice led this to be changed to:
-O 0 No optimization.
-O 1 Some level of optimization.
-O $n \quad$ Other, unspecified levels of optimization.
It is not always clear whether "good code generation" is the same thing as optimization. Simple optimizations of local actions do not usually affect the semantics of a program. The $-\mathbf{O} 0$ option has been included to accommodate the very particular nature of scientific calculations in a highly optimized environment; compilers make errors. Some degree of optimization is expected, even if it is not documented here, and the ability to shut it off completely could be important when porting an application. An implementation may treat $-\mathbf{O} 0$ as "do less than normal" if it wishes, but this is only meaningful if any of the operations it performs can affect the semantics of a program. It is highly dependent on the implementation whether doing less than normal is logical. It is not the intent of the $-\mathbf{O} 0$ option to ask for inefficient code generation, but rather to assure that any semantically visible optimization is suppressed.

The specification of standard library access is consistent with the $C$ compiler specification. Implementations are not required to have/usr/lib/libf.a, as many historical implementations do, but if not they are required to recognize $\mathbf{f}$ as a token.

External symbol size limits are in normative text; conforming applications need to know these limits. However, the minimum maximum symbol length should be taken as a constraint on a conforming application, not on an implementation, and consequently the action taken for a symbol exceeding the limit is unspecified. The minimum size for the external symbol table was added for similar reasons.
The CONSEQUENCES OF ERRORS section clearly specifies the behavior of the compiler when compilation or link-edit errors occur. The behavior of several historical implementations was examined, and the choice was made to be silent on the status of the executable, or a.out, file in the face of compiler or linker errors. If a linker writes the executable file, then links it on disk with $l \operatorname{seek}() \mathrm{s}$ and write ()s, the partially linked executable file can be left on disk and its execute bits turned off if the link edit fails. However, if the linker links the image in memory before writing the file to disk, it need not touch the executable file (if it already exists) because the link edit fails. Since both approaches are historical practice, a conforming application shall rely on the exit status of fort77, rather than on the existence or mode of the executable file.

The -g and -s options are not specified as mutually-exclusive. Historically these two options have been mutually-exclusive, but because both are so loosely specified, it seemed appropriate to leave their interaction unspecified.
The requirement that conforming applications specify compiler options separately is to reserve
the multi-character option name space for vendor-specific compiler options, which are known to exist in many historical implementations. Implementations are not required to recognize, for example, $-\mathbf{g c}$ as if it were $-\mathbf{g}-\mathbf{c}$; nor are they forbidden from doing so. The SYNOPSIS shows all of the options separately to highlight this requirement on applications.
Echoing filenames to standard error is considered a diagnostic message because it would otherwise be difficult to associate an error message with the erring file. They are described with "may" to allow implementations to use other methods of identifying files and to parallel the description in c99.

## FUTURE DIRECTIONS

A compilation system based on the ISO/IEC 1539: 1990 standard (Fortran-90) may be considered for a future version; it may have a different utility name from fort77.

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the FORTRAN Development Utilities option.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
fuser - list process IDs of all processes that have one or more files open

## SYNOPSIS

xSI fuser [-cfu] file...

## DESCRIPTION

The fuser utility shall write to standard output the process IDs of processes running on the local system that have one or more named files open. For block special devices, all processes using any file on that device are listed.
The fuser utility shall write to standard error additional information about the named files indicating how the file is being used.
Any output for processes running on remote systems that have a named file open is unspecified.
A user may need appropriate privilege to invoke the fuser utility.

## OPTIONS

The fuser utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-c The file is treated as a mount point and the utility shall report on any files open in the file system.
-f The report shall be only for the named files.
-u The user name, in parentheses, associated with each process ID written to standard output shall be written to standard error.

OPERANDS
The following operand shall be supported:
file A pathname on which the file or file system is to be reported.

## STDIN

Not used.

## INPUT FILES

The user database.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of fuser:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

The fuser utility shall write the process ID for each process using each file given as an operand to standard output in the following format:
"\%d", <process_id>

## STDERR

The fuser utility shall write diagnostic messages to standard error.
The fuser utility also shall write the following to standard error:

- The pathname of each named file is written followed immediately by a colon.
- For each process ID written to standard output, the character ' $c$ ' shall be written to standard error if the process is using the file as its current directory and the character ' $r$ ' shall be written to standard error if the process is using the file as its root directory. Implementations may write other alphabetic characters to indicate other uses of files.
- When the $-\mathbf{u}$ option is specified, characters indicating the use of the file shall be followed immediately by the user name, in parentheses, corresponding to the real user ID of the process. If the user name cannot be resolved from the real user ID of the process, the real user ID of the process shall be written instead of the user name.
When standard output and standard error are directed to the same file, the output shall be interleaved so that the filename appears at the start of each line, followed by the process ID and characters indicating the use of the file. Then, if the $-\mathbf{u}$ option is specified, the user name or user ID for each process using that file shall be written.

A <newline> shall be written to standard error after the last output described above for each file operand.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

The command:

```
fuser -fu .
```

writes to standard output the process IDs of processes that are using the current directory and writes to standard error an indication of how those processes are using the directory and the user names associated with the processes that are using the current directory.

```
fuser -c <mount point>
```

writes to standard output the process IDs of processes that are using any file in the file system which is mounted on <mount point> and writes to standard error an indication of how those processes are using the files.

```
fuser <mount point>
```

writes to standard output the process IDs of processes that are using the file which is named by <mount point> and writes to standard error an indication of how those processes are using the file.

```
fuser <block device>
```

writes to standard output the process IDs of processes that are using any file which is on the device named by <block device> and writes to standard error an indication of how those processes are using the file.

```
fuser --f <block device>
```

writes to standard output the process IDs of processes that are using the file <block device> itself and writes to standard error an indication of how those processes are using the file.

## RATIONALE

The definition of the fuser utility follows existing practice.

## FUTURE DIRECTIONS

None.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME gencat - generate a formatted message catalog

## SYNOPSIS

```
gencat catfile msgfile...
```

## DESCRIPTION

The gencat utility shall merge the message text source file msgfile into a formatted message catalog catfile. The file catfile shall be created if it does not already exist. If catfile does exist, its messages shall be included in the new catfile. If set and message numbers collide, the new message text defined in msgfile shall replace the old message text currently contained in catfile.

## OPTIONS

None.

## OPERANDS

The following operands shall be supported:
catfile A pathname of the formatted message catalog. If ${ }^{\prime}{ }^{\prime}$ ' is specified, standard output shall be used. The format of the message catalog produced is unspecified.
msgfile A pathname of a message text source file. If $\prime^{\prime \prime}$ is specified for an instance of $m s g$ file, standard input shall be used. The format of message text source files is defined in the EXTENDED DESCRIPTION section.

## STDIN

The standard input shall not be used unless a msgfile operand is specified as ' - '.

## INPUT FILES

The input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of gencat:
$L A N G \quad$ Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L \quad$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall not be used unless the catfile operand is specified as ${ }^{\prime}-{ }^{\prime}$.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

## EXTENDED DESCRIPTION

The content of a message text file shall be in the format defined as follows. Note that the fields of a message text source line are separated by a single <blank>. Any other <blank>s are considered to be part of the subsequent field.

## \$set $n$ comment

This line specifies the set identifier of the following messages until the next \$set or end-of-file appears. The $n$ denotes the set identifier, which is defined as a number in the range [1, \{NL_SETMAX\}] (see the <limits.h> header defined in the Base Definitions volume of IEEE Std 1003.1-200x). The application shall ensure that set identifiers are presented in ascending order within a single source file, but need not be contiguous. Any string following the set identifier shall be treated as a comment. If no \$set directive is specified in a message text source file, all messages shall be located in an implementation-defined default message set NL_SETD (see the <nl_types.h> header defined in the Base Definitions volume of IEEE Std 1003.1-200x).
\$delset $n$ comment
This line deletes message set $n$ from an existing message catalog. The $n$ denotes the set number [1, \{NL_SETMAX\}]. Any string following the set number shall be treated as a comment.
$\$$ comment A line beginning with '\$' followed by a <blank> shall be treated as a comment.
$m$ message-text
The $m$ denotes the message identifier, which is defined as a number in the range [1, [NL_MSGMAX\}] (see the <limits.h> header). The message-text shall be stored in the message catalog with the set identifier specified by the last \$set directive, and with message identifier $m$. If the message-text is empty, and a <blank> field separator is present, an empty string shall be stored in the message catalog. If a message source line has a message number, but neither a field separator nor message-text, the existing message with that number (if any) shall be deleted from the catalog. The application shall ensure that message identifiers are in ascending order within a single set, but need not be contiguous. The application shall ensure that the length of message-text is in the range [0, \{NL_TEXTMAX\}] (see the <limits.h> header).
\$quote $n \quad$ This line specifies an optional quote character $c$, which can be used to surround message-text so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty \$quote directive is supplied, no quoting of message-text shall be recognized.

Empty lines in a message text source file shall be ignored. The effects of lines starting with any character other than those defined above are implementation-defined.

Text strings can contain the special characters and escape sequences defined in the following table:

| Description | Symbol | Sequence |
| :--- | :--- | :--- |
| <newline> | NL(LF) | $\backslash \mathrm{n}$ |
| Horizontal-tab | HT | $\backslash t$ |
| <vertical-tab> | VT | $\backslash \mathrm{v}$ |
| <backspace> | BS | $\backslash \mathrm{b}$ |
| <carriage-return> | CR | $\backslash r$ |
| <form-feed> | FF | $\backslash \mathrm{f}$ |
| Backslash | $\backslash$ | $\backslash \backslash$ |
| Bit pattern | ddd | $\backslash d d d$ |

The escape sequence " $\backslash$ ddd" consists of backslash followed by one, two, or three octal digits, which shall be taken to specify the value of the desired character. If the character following a backslash is not one of those specified, the backslash shall be ignored.
Backslash ( ${ }^{\prime} \backslash$ ) followed by a <newline> is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

1 This line continues \}
to the next line
which shall be equivalent to:
1 This line continues to the next line

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Message catalogs produced by gencat are binary encoded, meaning that their portability cannot be guaranteed between different types of machine. Thus, just as C programs need to be recompiled for each type of machine, so message catalogs must be recreated via gencat.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

## CHANGE HISTORY

First released in Issue 3.

## Issue 6

The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
The gencat utility is moved from the XSI option to the Base.

NAME
get - get a version of an SCCS file (DEVELOPMENT)

## SYNOPSIS

XSI get [-begkmnlLpst] [-c cutoff] [-i list] [-r SID] [-x list] file...

## DESCRIPTION

The get utility shall generate a text file from each named SCCS file according to the specifications given by its options.

The generated text shall normally be written into a file called the g-file whose name is derived from the SCCS filename by simply removing the leading "s.".

## OPTIONS

The get utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-r SID Indicate the SCCS Identification String (SID) of the version (delta) of an SCCS file to be retrieved. The table shows, for the most useful cases, what version of an SCCS file is retrieved (as well as the SID of the version to be eventually created by delta if the -e option is also used), as a function of the SID specified.
-c cutoff Indicate the cutoff date-time, in the form:
$Y Y[M M[D D[H H[M M[S S]]]]$
For the $Y Y$ component, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range [00,68] shall refer to years 2000 to 2068 inclusive.
Note: It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2-digit year will change. (This would apply to all commands accepting a 2-digit year as input.)
No changes (deltas) to the SCCS file that were created after the specified cutoff date-time shall be included in the generated text file. Units omitted from the datetime default to their maximum possible values; for example, -c 7502 is equivalent to -c 750228235959 .
Any number of non-numeric characters may separate the various 2-digit pieces of the cutoff date-time. This feature allows the user to specify a cutoff date in the form: -c "77/2/2 9:22:25".
-e Indicate that the get is for the purpose of editing or making a change (delta) to the SCCS file via a subsequent use of delta. The -e option used in a get for a particular version (SID) of the SCCS file shall prevent further get commands from editing on the same SID until delta is executed or the $\mathbf{j}$ (joint edit) flag is set in the SCCS file. Concurrent use of get -e for different SIDs is always allowed.
If the g-file generated by get with a -e option is accidentally ruined in the process of editing, it may be regenerated by re-executing the get command with the $-\mathbf{k}$ option in place of the -e option.
SCCS file protection specified via the ceiling, floor, and authorized user list stored in the SCCS file shall be enforced when the -e option is used.

| 18700 | -b | Use with the -e option to indicate that the new delta should have an SID in a new |
| :---: | :---: | :---: |
| 18701 |  | branch as shown in the table below. This option shall be ignored if the $\mathbf{b}$ flag is not |
| 18702 |  | present in the file or if the retrieved delta is not a leaf delta. (A leaf delta is one that |
| 18703 |  | has no successors on the SCCS file tree.) |
| 18704 |  | Note: A branch delta may always be created from a non-leaf delta. |
| 18705 18706 | -i list | Indicate a list of deltas to be included (forced to be applied) in the creation of the generated file. The list has the following syntax: |
| 18707 |  | <list> : := <range> \| <list> , <range> |
| 18708 |  | <range> : : = SID \| SID - SID |
| 18709 |  | SID, the SCCS Identification of a delta, may be in any form shown in the "SID |
| 18710 |  | Specified" column of the table in the EXTENDED DESCRIPTION section, except |
| 18711 |  | that the result of supplying a partial SID is unspecified. A diagnostic message shall |
| 18712 |  | be written if the first SID in the range is not an ancestor of the second SID in the |
| 18713 |  | range. |
| 18714 | -x list | Indicate a list of deltas to be excluded (forced not to be applied) in the creation of |
| 18715 |  | the generated file. See the -i option for the list format. |
| 18716 | -k | Suppress replacement of identification keywords (see below) in the retrieved text |
| 18717 |  | by their value. The -k option shall be implied by the -e option. |
| 18718 | -1 | Write a delta summary into an 1-file. |
| 18719 | -L | Write a delta summary to standard output. All informative output that normally is |
| 18720 |  | written to standard output shall be written to standard error instead, unless the -s |
| 18721 |  | option is used, in which case it shall be suppressed. |
| 18722 | -p | Write the text retrieved from the SCCS file to the standard output. No g-file shall |
| 18723 |  | be created. All informative output that normally goes to the standard output shall |
| 18724 |  | go to standard error instead, unless the -s option is used, in which case it shall |
| 18725 |  | disappear. |
| 18726 | -s | Suppress all informative output normally written to standard output. However, |
| 18727 |  | fatal error messages (which shall always be written to the standard error) shall |
| 18728 |  | emain unaffected. |
| 18729 | -m | Precede each text line retrieved from the SCCS file by the SID of the delta that |
| 18730 |  | inserted the text line in the SCCS file. The format shall be: |
| 18731 |  | "\%s\t\%s", <SID>, <text line> |
| 18732 | -n | Precede each generated text line with the \%M\% identification keyword value (see |
| 18733 |  | below). The format shall be: |
| 18734 |  | "\%s t \%s", <\%M\% value>, <text line> |
| 18735 |  | When both the $\mathbf{- m}$ and $-\mathbf{n}$ options are used, the <text line> shall be replaced by the |
| 18736 |  | -m option-generated format. |
| 18737 18738 | -g | Suppress the actual retrieval of text from the SCCS file. It is primarily used to generate an l-file, or to verify the existence of a particular SID. |
| 18739 | -t | Use to access the most recently created (top) delta in a given release (for example, |
| 18740 |  | -r 1), or release and level (for example, -r 1.2). |

## OPERANDS

The following operands shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the get utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with $\mathbf{s}$.) and unreadable files shall be silently ignored.

If exactly one file operand appears, and it is ' - ', the standard input shall be read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

## STDIN

The standard input shall be a text file used only if the file operand is specified as ' - '. Each line of the text file shall be interpreted as an SCCS pathname.

## INPUT FILES

The SCCS files shall be files of an unspecified format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of get:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output (or standard error, if the $-\mathbf{p}$ option is used).
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TZ Determine the timezone in which the times and dates written in the SCCS file are evaluated. If the $T Z$ variable is unset or NULL, an unspecified system default timezone is used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

For each file processed, get shall write to standard output the SID being accessed and the number of lines retrieved from the SCCS file, in the following format:

```
"%s\n%d lines\n", <SID>, <number of lines>
```

If the -e option is used, the SID of the delta to be made shall appear after the SID accessed and before the number of lines generated, in the POSIX locale:

```
"%s\nnew delta %s\n%d lines\n", <SID accessed>,
    <SID to be made>, <number of lines>
```

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the lines shown in one of the preceding formats:

"\n\%s:\n", <pathname>
If the -L option is used, a delta summary shall be written following the format specified below for 1-files.

If the $-\mathbf{i}$ option is used, included deltas shall be listed following the notation, in the POSIX locale:
"Included: \n"
If the $-\mathbf{x}$ option is used, excluded deltas shall be listed following the notation, in the POSIX locale:
"Excluded: \n"
If the $-\mathbf{p}$ or $-\mathbf{L}$ options are specified, the standard output shall consist of the text retrieved from the SCCS file.

## STDERR

The standard error shall be used only for diagnostic messages, except if the $-\mathbf{p}$ or $-\mathbf{L}$ options are specified, it shall include all informative messages normally sent to standard output.

## OUTPUT FILES

Several auxiliary files may be created by get. These files are known generically as the g-file, lfile, p-file, and z-file. The letter before the hyphen is called the tag. An auxiliary filename shall be formed from the SCCS filename: the application shall ensure that the last component of all SCCS filenames is of the form s.module-name; the auxiliary files shall be named by replacing the leading s with the tag. The g-file shall be an exception to this scheme: the g-file is named by removing the s. prefix. For example, for s.xyz.c, the auxiliary filenames would be xyz.c, l.xyz.c, p.xyz.c, and z.xyz.c, respectively.

The g-file, which contains the generated text, shall be created in the current directory (unless the -p option is used). A g-file shall be created in all cases, whether or not any lines of text were generated by the get. It shall be owned by the real user. If the $-\mathbf{k}$ option is used or implied, the g-file shall be writable by the owner only (read-only for everyone else); otherwise, it shall be read-only. Only the real user need have write permission in the current directory.
The l-file shall contain a table showing which deltas were applied in generating the retrieved text. The l-file shall be created in the current directory if the -1 option is used; it shall be readonly and it is owned by the real user. Only the real user need have write permission in the current directory.
Lines in the l-file shall have the following format:
$" \% \mathrm{C} \% \mathrm{C} \% \mathrm{C} \Delta \% \mathrm{~S} \backslash \mathrm{t} \% \mathrm{~S} \Delta \% \mathrm{~s} \backslash \mathrm{n} ",<c o d e 1>$, <code2>, <code3>, <SID>, <date-time>, <login>
where the entries are:
<code1> A <space> if the delta was applied; ' *' otherwise.
<code2> A <space> if the delta was applied or was not applied and ignored; ' ${ }^{* \prime}$ if the delta was not applied and was not ignored.
<code3> A character indicating a special reason why the delta was or was not applied:
I Included.
X Excluded.
C Cut off (by a -c option).
<date-time> Date and time (using the format of the date utility's $\% \mathrm{y} / \% \mathrm{~m} / \% \mathrm{~d} \% \mathrm{~T}$ conversion specification format) of creation.
<login> Login name of person who created delta.
The comments and MR data shall follow on subsequent lines, indented one <tab>. A blank line shall terminate each entry.

The p-file shall be used to pass information resulting from a get with a -e option along to delta. Its contents shall also be used to prevent a subsequent execution of get with a -e option for the same SID until delta is executed or the joint edit flag, $\mathbf{j}$, is set in the SCCS file. The p-file shall be created in the directory containing the SCCS file and the application shall ensure that the effective user has write permission in that directory. It shall be writable by owner only, and owned by the effective user. Each line in the p-file shall have the following format:

```
"%s\Delta%s\Delta%s\Delta%s%s%s\n", <g-file SID>,
    <SID of new delta>, <login-name of real user>,
    <date-time>, <i-value>, <x-value>
```

where <i-value> uses the format " " if no -i option was specified, and shall use the format:

```
"\Delta-i%s", <-i option option-argument>
```

if a -i option was specified and $\langle x$-value $>$ uses the format " " if no $-\mathbf{x}$ option was specified, and shall use the format:
" $\Delta-x \% s ",<-x$ option option-argument>
if a -x option was specified. There can be an arbitrary number of lines in the $\mathbf{p}$-file at any time; no two lines shall have the same new delta SID.
The z-file shall serve as a lock-out mechanism against simultaneous updates. Its contents shall be the binary process ID of the command (that is, get) that created it. The $\mathbf{z}$-file shall be created in the directory containing the SCCS file for the duration of get. The same protection restrictions as those for the $\mathbf{p}$-file shall apply for the $\mathbf{z}$-file. The $\mathbf{z}$-file shall be created read-only.

## EXTENDED DESCRIPTION

| Determination of SCCS Identification String |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $\begin{gathered} \text { SID }^{*} \\ \text { Specified } \end{gathered}$ | -b Keyletter Used $\dagger$ | Other Conditions | SID <br> Retrieved | SID of Delta to be Created |
| none $\ddagger$ | no | R defaults to mR | mR.mL | mR.(mL+1) |
| none $\ddagger$ | yes | R defaults to mR | mR.mL | mR.mL.(mB+1). 1 |
| R | no | $\mathrm{R}>\mathrm{mR}$ | mR.mL | R.1*** |
| R | no | $\mathrm{R}=\mathrm{mR}$ | mR.mL | mR.(mL+1) |
| R | yes | $\mathrm{R}>\mathrm{mR}$ | mR.mL | mR.mL.(mB+1). 1 |
| R | yes | $\mathrm{R}=\mathrm{mR}$ | mR.mL | mR.mL. $(\mathrm{mB}+1) .1$ |
| R | - | $\mathrm{R}<\mathrm{mR}$ and R does not exist | hR.mL** | hR.mL.(mB+1). 1 |
| R | - | Trunk successor in release $>\mathrm{R}$ and R exists | R.mL | R.mL.(mB+1). 1 |
| R.L | no | No trunk successor | R.L | R.(L+1) |
| R.L | yes | No trunk successor | R.L | R.L.(mB+1).1 |
| R.L | - | Trunk successor in release $\geq \mathrm{R}$ | R.L | R.L.(mB+1).1 |
| R.L.B | no | No branch successor | R.L.B.mS | R.L.B. $(\mathrm{mS}+1)$ |
| R.L.B | yes | No branch successor | R.L.B.mS | R.L.(mB+1). 1 |
| R.L.B.S | no | No branch successor | R.L.B.S | R.L.B.(S+1) |
| R.L.B.S | yes | No branch successor | R.L.B.S | R.L.(mB+1).1 |
| R.L.B.S | - | Branch successor | R.L.B.S | R.L.(mB+1).1 |

* $\quad$, L, B, and $S$ are the release, level, branch, and sequence components of the SID, respectively; m means maximum. Thus, for example, R.mL means "the maximum level number within release R"; R.L.(mB+1). 1 means "the first sequence number on the new branch (that is, maximum branch number plus one) of level $L$ within release $R^{\prime \prime}$. Note that if the SID specified is of the form R.L, R.L.B, or R.L.B.S, each of the specified components shall exist.
** $\quad h R$ is the highest existing release that is lower than the specified, nonexistent, release $R$.
*** This is used to force creation of the first delta in a new release.
$\dagger \quad$ The $-\mathbf{b}$ option is effective only if the $\mathbf{b}$ flag is present in the file. An entry of ${ }^{\prime} \mathbf{~}^{\prime}$ means "irrelevant".
$\ddagger \quad$ This case applies if the $\mathbf{d}$ (default SID) flag is not present in the file. If the $\mathbf{d}$ flag is present in the file, then the SID obtained from the $\mathbf{d}$ flag is interpreted as if it had been specified on the command line. Thus, one of the other cases in this table applies.

## System Date and Time

When a g-file is generated, the creation time of deltas in the SCCS file may be taken into account. If any of these times are apparently in the future, the behavior is unspecified.

## APPLICATION USAGE

Problems can arise if the system date and time have been modified (for example, put forward and then back again, or unsynchronized clocks across a network) and can also arise when different values of the TZ environment variable are used.

Problems of a similar nature can also arise for the operation of the delta utility, which compares the previous file body against the working file as part of its normal operation.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

The -lp option may be withdrawn in a future version.

## CHANGE HISTORY

First released in Issue 2.
Issue 5
A correction is made to the first format string in STDOUT.
The interpretation of the $Y Y$ component of the -c cutoff argument is noted.
Issue 6
The obsolescent SYNOPSIS is removed, removing the $-\mathbf{l p}$ option.
The normative text is reworded to avoid use of the term "must" for application requirements.
The Open Group Corrigendum U025/5 is applied, correcting text in the OPTIONS section.
The Open Group Corrigendum U048/1 is applied.
The Open Group Interpretation PIN4C. 00014 is applied.
The Open Group Base Resolution bwg2001-007 is applied as follows:

- The EXTENDED DESCRIPTION section is updated to make partial SID handling unspecified, reflecting common usage, and to clarify SID ranges.
- New text is added to the EXTENDED DESCRIPTION and APPLICATION USAGE sections regarding how the system date and time may be taken into account.
- The TZ environment variable is added to the ENVIRONMENT VARIABLES section.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
getconf - get configuration values

## SYNOPSIS

```
getconf [-v specification] system_var
getconf [-v specification] path_var pathname
```

## DESCRIPTION

In the first synopsis form, the getconf utility shall write to the standard output the value of the variable specified by the system_var operand.
In the second synopsis form, the getconf utility shall write to the standard output the value of the variable specified by the path_var operand for the path specified by the pathname operand.
The value of each configuration variable shall be determined as if it were obtained by calling the function from which it is defined to be available by this volume of IEEE Std 1003.1-200x or by the System Interfaces volume of IEEE Std 1003.1-200x (see the OPERANDS section). The value shall reflect conditions in the current operating environment.

## OPTIONS

The getconf utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-v specification
Indicate a specific specification and version for which configuration variables shall be determined. If this option is not specified, the values returned correspond to an implementation default conforming compilation environment.
If the command:

```
getconf _POSIX_V7_ILP32_OFF32
```

does not write " $-1 \backslash \mathrm{n}$ " or "undefined $\backslash \mathrm{n}$ " to standard output, then commands of the form:
getconf -v POSIX_V7_ILP32_OFF32 ...
determine values for configuration variables corresponding to the POSIX_V7_ILP32_OFF32 compilation environment specified in c99, the EXTENDED DESCRIPTION.
If the command:
getconf -POSIX_V7_ILP32_OFFBIG
does not write " $-1 \backslash \mathrm{n}$ " or "undefined $\backslash \mathrm{n}$ " to standard output, then commands of the form:

```
getconf -v POSIX_V7_ILP32_OFFBIG ...
```

determine values for configuration variables corresponding to the POSIX_V7_ILP32_OFFBIG compilation environment specified in c99, the EXTENDED DESCRIPTION.

If the command:

```
getconf _POSIX_V7_LP64_OFF64
```

does not write " $-1 \backslash \mathrm{n}$ " or "undefined $\backslash \mathrm{n}$ " to standard output, then commands of
the form:

```
getconf -v POSIX_V7_LP64_OFF64 ...
```

determine values for configuration variables corresponding to the POSIX_V7_LP64_OFF64 compilation environment specified in c99, the EXTENDED DESCRIPTION.

If the command:

```
getconf __POSIX_V7_LPBIG_OFFBIG
```

does not write " $-1 \backslash \mathrm{n}$ " or "undefined $\backslash \mathrm{n}$ " to standard output, then commands of the form:

```
getconf -v POSIX_V7_LPBIG_OFFBIG ...
determine values for configuration variables corresponding to the
POSIX_V7_LPBIG_OFFBIG compilation environment specified in c99, the
EXTENDED DESCRIPTION.
```

## OPERANDS

The following operands shall be supported:
path_var A name of a configuration variable. All of the variables in the Variable column of the table in the DESCRIPTION of the fpathconf() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, without the enclosing braces, shall be supported. The implementation may add other local variables.
pathname A pathname for which the variable specified by path_var is to be determined.
system_var A name of a configuration variable. All of the following variables shall be supported:

- The names in the Variable column of the table in the DESCRIPTION of the sysconf() function in the System Interfaces volume of IEEE Std 1003.1-200x, except for the entries corresponding to _SC_CLK_TCK, _SC_GETGR_R_SIZE_MAX, and _SC_GETPW_R_SIZE_MAX, without the enclosing braces.

For compatibility with earlier versions, the following variable names shall also be supported:

```
POSIX2_C_BIND
POSIX2_C_DEV
POSIX2_CHAR_TERM
POSIX2_FORT_DEV
POSIX2_FORT_RUN
POSIX2_LOCALEDEF
POSIX2_SW_DEV
                POSIX2_UPE
                POSIX2_VERSION
```

and shall be equivalent to the same name prefixed with an underscore. This requirement may be removed in a future version.

- The names of the symbolic constants used as the name argument of the confstr() function in the System Interfaces volume of IEEE Std 1003.1-200x, without the _CS_ prefix.
- The names of the symbolic constants listed under the headings "Maximum Values" and "Minimum Values" in the description of the <limits.h> header in the Base Definitions volume of IEEE Std 1003.1-200x, without the enclosing braces.

For compatibility with earlier versions, the following variable names shall also be supported:

```
POSIX2_BC_BASE_MAX
POSIX2_BC_DIM_MAX
POSIX2_BC_SCALE_MAX
POSIX2_BC_STRING_MAX
POSIX2_COLL_WEIGHTS_MAX
POSIX2_EXPR_NEST_MAX
POSIX2_LINE_MAX
POSIX2_RE_DUP_MAX
```

and shall be equivalent to the same name prefixed with an underscore. This requirement may be removed in a future version.

The implementation may add other local values.

## STDIN

Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of getconf:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If the specified variable is defined on the system and its value is described to be available from the confstr() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, its value shall be written in the following format:
"\%s\n", <value>
Otherwise, if the specified variable is defined on the system, its value shall be written in the following format:
"\%d\n", <value>

If the specified variable is valid, but is undefined on the system, getconf shall write using the following format:
"undefined $\backslash n$ "
If the variable name is invalid or an error occurs, nothing shall be written to standard output.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The specified variable is valid and information about its current state was written successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

The following example illustrates the value of \{NGROUPS_MAX\}:
getconf NGROUPS_MAX
The following example illustrates the value of \{NAME_MAX\} for a specific directory:

```
getconf NAME_MAX /usr
```

The following example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
        if [ "$value" = "undefined" ]; then
            echo PATH_MAX in \usr is infinite.
        else
        echo PATH_MAX in /usr/is $value.
        fi
else
    echo Error in getconf.
fi
```

Note that:
sysconf(_SC_POSIX_C_BIND);
and:
system("getconf POSIX2_C_BIND");
in a C program could give different answers. The sysconf() call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation; the system () call to getconf always supplies a value corresponding to conditions when the program is executed.

## RATIONALE

The original need for this utility, and for the confstr() function, was to provide a way of finding the configuration-defined default value for the PATH environment variable. Since PATH can be modified by the user to include directories that could contain utilities replacing the standard utilities, shell scripts need a way to determine the system-supplied PATH environment variable value that contains the correct search path for the standard utilities. It was later suggested that access to the other variables described in this volume of IEEE Std 1003.1-200x could also be useful to applications.

This functionality of getconf would not be adequately subsumed by another command such as:

```
grep var /etc/conf
```

because such a strategy would provide correct values for neither those variables that can vary at runtime, nor those that can vary depending on the path.
Early proposal versions of getconf specified exit status 1 when the specified variable was valid, but not defined on the system. The output string "undefined" is now used to specify this case with exit code 0 because so many things depend on an exit code of zero when an invoked utility is successful.

## FUTURE DIRECTIONS

None.
SEE ALSO
c99, the Base Definitions volume of IEEE Std 1003.1-200x, <limits.h>, the System Interfaces volume of IEEE Std 1003.1-200x, confstr ( ), pathconf( ), sysconf( ), system ()

## CHANGE HISTORY

First released in Issue 4.
Issue 5
In the OPERANDS section:

- \{NL_MAX\} is changed to $\left\{N L \_N M A X\right\}$.
- Entries beginning NL_ are deleted from the list of standard configuration variables.
- The list of variables previously marked UX is merged with the list marked EX.
- Operands are added to support new Option Groups.
- Operands are added so that getconf can determine supported programming environments.

## Issue 6

The Open Group Corrigendum U029/4 is applied, correcting the example command in the last paragraph of the OPTIONS section.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Operands are added to determine supported programming environments.

This reference page is updated for alignment with the ISO/IEC 9899:1999 standard. Specifically, new macros for $c 99$ programming environments are introduced.
XSI marked system_var (XBS5_*) values are marked LEGACY.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/27 is applied, correcting the descriptions of path_var and system_var in the OPERANDS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

getopts - parse utility options

## SYNOPSIS

```
getopts optstring name [arg...]
```

## DESCRIPTION

The getopts utility shall retrieve options and option-arguments from a list of parameters. It shall support the Utility Syntax Guidelines 3 to 10, inclusive, described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

Each time it is invoked, the getopts utility shall place the value of the next option in the shell variable specified by the name operand and the index of the next argument to be processed in the shell variable OPTIND. Whenever the shell is invoked, OPTIND shall be initialized to 1 .

When the option requires an option-argument, the getopts utility shall place it in the shell variable OPTARG. If no option was found, or if the option that was found does not have an option-argument, OPTARG shall be unset.

If an option character not contained in the optstring operand is found where an option character is expected, the shell variable specified by name shall be set to the question-mark (' ?') character. In this case, if the first character in optstring is a colon (' $:^{\prime}$ ), the shell variable OPTARG shall be set to the option character found, but no output shall be written to standard error; otherwise, the shell variable OPTARG shall be unset and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in getopts processing.
If an option-argument is missing:

- If the first character of optstring is a colon, the shell variable specified by name shall be set to the colon character and the shell variable OPTARG shall be set to the option character found.
- Otherwise, the shell variable specified by name shall be set to the question-mark character, the shell variable OPTARG shall be unset, and a diagnostic message shall be written to standard error. This condition shall be considered to be an error detected in the way arguments were presented to the invoking application, but shall not be an error in getopts processing; a diagnostic message shall be written as stated, but the exit status shall be zero.

When the end of options is encountered, the getopts utility shall exit with a return value greater than zero; the shell variable OPTIND shall be set to the index of the first non-option-argument, where the first "--" argument is considered to be an option-argument if there are no other non-option-arguments appearing before it, or the value "\$\#"+1 if there are no non-optionarguments; the name variable shall be set to the question-mark character. Any of the following shall identify the end of options: the special option "--", finding an argument that does not begin with $\mathrm{a}^{\prime}-^{\prime}$, or encountering an error.

The shell variables OPTIND and OPTARG shall be local to the caller of getopts and shall not be exported by default.

The shell variable specified by the name operand, OPTIND, and OPTARG shall affect the current shell execution environment; see Section 2.12 (on page 61).

If the application sets OPTIND to the value 1 , a new set of parameters can be used: either the current positional parameters or new arg values. Any other attempt to invoke getopts multiple times in a single shell execution environment with parameters (positional parameters or arg operands) that are not the same in all invocations, or with an OPTIND value modified to be a value other than 1, produces unspecified results.

## OPTIONS

## OPERANDS

The following operands shall be supported:
optstring A string containing the option characters recognized by the utility invoking getopts. If a character is followed by a colon, the option shall be expected to have an argument, which should be supplied as a separate argument. Applications should specify an option character and its option-argument as separate arguments, but getopts shall interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null optionargument need not be recognized if it is not supplied as a separate argument when getopts is invoked. (See also the getopt () function defined in the System Interfaces volume of IEEE Std 1003.1-200x.) The characters question-mark and colon shall not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in OPTARG shall be stripped of the option character and the ${ }^{\prime}-$ '. The first character in optstring determines how getopts behaves if an option character is not known or an option-argument is missing.
name The name of a shell variable that shall be set by the getopts utility to the option character that was found.

The getopts utility by default shall parse positional parameters passed to the invoking shell procedure. If args are given, they shall be parsed instead of the positional parameters.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of getopts:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
OPTIND This variable shall be used by the getopts utility as the index of the next argument to be processed.

ASYNCHRONOUS EVENTS
Default.

## STDOUT

Not used.

## STDERR

 an unspecified format:```
basename "$0"
```

may be used. message.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

 of the following:
## EXAMPLES

aflag=
bflag=
while getopts $a b:$ name
do

Whenever an error is detected and the first character in the optstring operand is not a colon (':'), a diagnostic message shall be written to standard error with the following information in

- The invoking program name shall be identified in the message. The invoking program name shall be the value of the shell special parameter 0 (see Section 2.5 .2 (on page 34)) at the time the getopts utility is invoked. A name equivalent to:
- If an option is found that was not specified in optstring, this error is identified and the invalid option character shall be identified in the message.
- If an option requiring an option-argument is found, but an option-argument is not found, this error shall be identified and the invalid option character shall be identified in the

The following exit values shall be returned:
0 An option, specified or unspecified by optstring, was found.
$>0$ The end of options was encountered or an error occurred.

Since getopts affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one

```
(getopts abc value "$@")
nohup getopts
find . -exec getopts ... \;
```

it does not affect the shell variables in the caller's environment.
Note that shell functions share OPTIND with the calling shell even though the positional parameters are changed. If the calling shell and any of its functions uses getopts to parse arguments, the results are unspecified.

The following example script parses and displays its arguments:

```
        case $name in
        a) aflag=1;;
        b) bflag=1
            bval="$OPTARG"; ;
        printf "Usage: %s: [-a] [-b value] args\n" $0
            exit 2;;
        esac
done
if [ ! -z "$aflag" ]; then
        printf "Option -a specified\n"
fi
if [ ! -z "$bflag" ]; then
        printf 'Option -b "%s" specified\n' "$bval"
fi
shift $(($OPTIND - 1))
printf "Remaining arguments are: %s\n" "$*"
```

## RATIONALE

The getopts utility was chosen in preference to the System V getopt utility because getopts handles option-arguments containing <blank>s.

The OPTARG variable is not mentioned in the ENVIRONMENT VARIABLES section because it does not affect the execution of getopts, it is one of the few "output-only" variables used by the standard utilities.
The colon is not allowed as an option character because that is not historical behavior, and it violates the Utility Syntax Guidelines. The colon is now specified to behave as in the KornShell version of the getopts utility; when used as the first character in the optstring operand, it disables diagnostics concerning missing option-arguments and unexpected option characters. This replaces the use of the OPTERR variable that was specified in an early proposal.
The formats of the diagnostic messages produced by the getopts utility and the getopt() function are not fully specified because implementations with superior ("friendlier") formats objected to the formats used by some historical implementations. The standard developers considered it important that the information in the messages used be uniform between getopts and getopt(). Exact duplication of the messages might not be possible, particularly if a utility is built on another system that has a different getopt() function, but the messages must have specific information included so that the program name, invalid option character, and type of error can be distinguished by a user.
Only a rare application program intercepts a getopts standard error message and wants to parse it. Therefore, implementations are free to choose the most usable messages they can devise. The following formats are used by many historical implementations:

```
"%s: illegal option -- %c\n", <program name>, <option character>
"%s: option requires an argument -- %c\n", <program name>, \
    <option character>
```

Historical shells with built-in versions of getopt() or getopts have used different formats, frequently not even indicating the option character found in error.

## NAME

grep - search a file for a pattern

## SYNOPSIS

$$
\begin{aligned}
& \text { grep [-E|-F] [-c|-l|-q] [-insvx] -e pattern_list } \\
& \text { [-e pattern_list]... [-f pattern_file]... [file...] } \\
& \text { grep [-E } \mid-\mathrm{F}] \text { [-c|-l|-q] [-insvx] [-e pattern_list]... } \\
& -\mathrm{f} \text { patern_file [-f pattern_file]... [file...] } \\
& \text { grep [-E } \mid-\mathrm{F}] \text { [-c|-l|-q] [-insvx] pattern_list [file...] }
\end{aligned}
$$

## DESCRIPTION

The grep utility shall search the input files, selecting lines matching one or more patterns; the types of patterns are controlled by the options specified. The patterns are specified by the $-\mathbf{e}$ option, $-\mathbf{f}$ option, or the pattern_list operand. The pattern_list's value shall consist of one or more patterns separated by <newline>s; the pattern_file's contents shall consist of one or more patterns terminated by <newline>. By default, an input line shall be selected if any pattern, treated as an entire basic regular expression (BRE) as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions, matches any part of the line excluding the terminating <newline>; a null BRE shall match every line. By default, each selected input line shall be written to the standard output.

Regular expression matching shall be based on text lines. Since a <newline> separates or terminates patterns (see the $-\mathbf{e}$ and $-\mathbf{f}$ options below), regular expressions cannot contain a <newline>. Similarly, since patterns are matched against individual lines (excluding the terminating <newline>s) of the input, there is no way for a pattern to match a <newline> found in the input.

## OPTIONS

The grep utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-E Match using extended regular expressions. Treat each pattern specified as an ERE, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions. If any entire ERE pattern matches some part of an input line excluding the terminating <newline>, the line shall be matched. A null ERE shall match every line.
-F Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line shall be matched. A null string shall match every line.
-c Write only a count of selected lines to standard output.
-e pattern_list
Specify one or more patterns to be used during the search for input. The application shall ensure that patterns in pattern_list are separated by a <newline>. A null pattern can be specified by two adjacent <newline>s in pattern_list. Unless the $-\mathbf{E}$ or $-\mathbf{F}$ option is also specified, each pattern shall be treated as a BRE, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. Multiple -e and -f options shall be accepted by the grep utility. All of the specified patterns shall be used when matching lines, but the order of evaluation is unspecified.

```
-f pattern_file
Read one or more patterns from the file named by the pathname pattern_file. Patterns in pattern_file shall be terminated by a <newline>. A null pattern can be specified by an empty line in pattern_file. Unless the \(-\mathbf{E}\) or \(-\mathbf{F}\) option is also specified, each pattern shall be treated as a BRE, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions.
-i Perform pattern matching in searches without regard to case; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.2, Regular Expression General Requirements.
-1 (The letter ell.) Write only the names of files containing selected lines to standard output. Pathnames shall be written once per file searched. If the standard input is searched, a pathname of " (standard input)" shall be written, in the POSIX locale. In other locales, "standard input " may be replaced by something more appropriate in those locales.
-n Precede each output line by its relative line number in the file, each file starting at line 1. The line number counter shall be reset for each file processed.
\(-\mathbf{q} \quad\) Quiet. Nothing shall be written to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.
-s Suppress the error messages ordinarily written for nonexistent or unreadable files. Other error messages shall not be suppressed.
\(\mathbf{- v} \quad\) Select lines not matching any of the specified patterns. If the \(\mathbf{- v}\) option is not specified, selected lines shall be those that match any of the specified patterns.
-x Consider only input lines that use all characters in the line excluding the terminating <newline> to match an entire fixed string or regular expression to be matching lines.
```

## OPERANDS

```
The following operands shall be supported:
pattern_list Specify one or more patterns to be used during the search for input. This operand shall be treated as if it were specified as - \(\mathbf{e}\) pattern_list.
file A pathname of a file to be searched for the patterns. If no file operands are specified, the standard input shall be used.
```

## STDIN

```
The standard input shall be used only if no file operands are specified. See the INPUT FILES section.
```

## INPUT FILES

```
The input files shall be text files.
```

## ENVIRONMENT VARIABLES

```
The following environment variables shall affect the execution of grep:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
```

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If the $-\mathbf{l}$ option is in effect, the following shall be written for each file containing at least one selected input line:
"\%s\n", <file>
Otherwise, if more than one file argument appears, and $-\mathbf{q}$ is not specified, the grep utility shall prefix each output line by:
"\%s:", <file>
The remainder of each output line shall depend on the other options specified:

- If the -c option is in effect, the remainder of each output line shall contain:

```
"%d\n", <count>
```

- Otherwise, if $-\mathbf{c}$ is not in effect and the $-\mathbf{n}$ option is in effect, the following shall be written to standard output:

```
"%d:", <line number>
```

- Finally, the following shall be written to standard output:

```
"\%s", <selected-line contents>
```

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 One or more lines were selected.
1 No lines were selected.
>1 An error occurred.

## CONSEQUENCES OF ERRORS

If the $-\mathbf{q}$ option is specified, the exit status shall be zero if an input line is selected, even if an error was detected. Otherwise, default actions shall be performed.

## APPLICATION USAGE

Care should be taken when using characters in pattern_list that may also be meaningful to the command interpreter. It is safest to enclose the entire pattern_list argument in single quotes:
'...'
The -e pattern_list option has the same effect as the pattern_list operand, but is useful when pattern_list begins with the hyphen delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.
Multiple -e and -f options are accepted and grep uses all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)
The $-\mathbf{q}$ option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it exits zero if it finds a match even if grep detected an access or read error on earlier file operands).

## EXAMPLES

1. To find all uses of the word "Posix" (in any case) in file text.mm and write with line numbers:
grep -i -n posix text.mm
2. To find all empty lines in the standard input:
```
    grep ^$
Or:
```

3. Both of the following commands print all lines containing strings "abc" or "def" or both:
```
grep -E 'abc/def'
grep -F 'abc
def'
```

4. Both of the following commands print all lines matching exactly "abc" or "def":
```
grep -E '^abc\$|`def\$'
grep -F -x 'abc
def'
```

## RATIONALE

This grep has been enhanced in an upwards-compatible way to provide the exact functionality of the historical egrep and fgrep commands as well. It was the clear intention of the standard developers to consolidate the three greps into a single command.
The old egrep and fgrep commands are likely to be supported for many years to come as implementation extensions, allowing historical applications to operate unmodified.
Historical implementations usually silently ignored all but one of multiply-specified -e and -f options, but were not consistent as to which specification was actually used.

The -b option was omitted from the OPTIONS section because block numbers are implementation-defined.
The System V restriction on using - to mean standard input was omitted.
A definition of action taken when given a null BRE or ERE is specified. This is an error condition in some historical implementations.

The -1 option previously indicated that its use was undefined when no files were explicitly named. This behavior was historical and placed an unnecessary restriction on future implementations. It has been removed.

The historical BSD grep -s option practice is easily duplicated by redirecting standard output to $/ \mathrm{dev} / \mathrm{null}$. The -s option required here is from System V.
The $-\mathbf{x}$ option, historically available only with fgrep, is available here for all of the nonobsolescent versions.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/28 is applied, correcting the examples using the grep $-\mathbf{F}$ option which did not match the normative description of the $-\mathbf{F}$ option.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-98 is applied, updating the STDOUT section.

NAME
hash - remember or report utility locations

## SYNOPSIS

```
hash [utility...]
    hash -r
```

## DESCRIPTION

The hash utility shall affect the way the current shell environment remembers the locations of utilities found as described in Section 2.9.1.1 (on page 48). Depending on the arguments specified, it shall add utility locations to its list of remembered locations or it shall purge the contents of the list. When no arguments are specified, it shall report on the contents of the list.
Utilities provided as built-ins to the shell shall not be reported by hash.

## OPTIONS

The hash utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-r Forget all previously remembered utility locations.
OPERANDS
The following operand shall be supported:
utility The name of a utility to be searched for and added to the list of remembered locations. If utility contains one or more slashes, the results are unspecified.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of hash:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the location of utility, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

 normal command search process.
## STDERR

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

 following:nohup hash -r simplest form, this can be:
PATH="\$PATH" by default.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

The standard output of hash shall be used when no arguments are specified. Its format is unspecified, but includes the pathname of each utility in the list of remembered locations for the current shell environment. This list shall consist of those utilities named in previous hash invocations that have been invoked, and may contain those invoked and found through the

The standard error shall be used only for diagnostic messages.

The following exit values shall be returned:

Since hash affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the
find. -type f xargs hash
it does not affect the command search process of the caller's environment.
The hash utility may be implemented as an alias-for example, alias $\mathbf{- t}-$, in which case utilities found through normal command search are not listed by the hash command.

The effects of hash -r can also be achieved portably by resetting the value of PATH; in the

The use of hash with utility names is unnecessary for most applications, but may provide a performance improvement on a few implementations; normally, the hashing process is included

## CHANGE HISTORY

First released in Issue 2.
Issue 7
The hash utility is moved from the XSI option to the Base.

NAME
head - copy the first part of files

## SYNOPSIS

```
head [-n number] [file...]
```

## DESCRIPTION

The head utility shall copy its input files to the standard output, ending the output for each file at a designated point.

Copying shall end at the point in each input file indicated by the $\mathbf{- n}$ number option. The optionargument number shall be counted in units of lines.

## OPTIONS

The head utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-n number The first number lines of each input file shall be copied to standard output. The application shall ensure that the number option-argument is a positive decimal integer.
When a file contains less than number lines, it shall be copied to standard output in its entirety. This shall not be an error.

If no options are specified, head shall act as if $-\mathbf{n} 10$ had been specified.

## OPERANDS

The following operand shall be supported:
file A pathname of an input file. If no file operands are specified, the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

Input files shall be text files, but the line length is not restricted to \{LINE_MAX\} bytes.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of head:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

## xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall contain designated portions of the input files.
If multiple file operands are specified, head shall precede the output for each with the header:
" \n==> \%s <==\n", <pathname>
except that the first header written shall not include the initial <newline>.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The obsolescent -number form is withdrawn in this version. Applications should use the -n number option.

## EXAMPLES

To write the first ten lines of all files (except those with a leading period) in the directory:
head *

## RATIONALE

Although it is possible to simulate head with sed 10 q for a single file, the standard developers decided that the popularity of head on historical BSD systems warranted its inclusion alongside tail.

This standard version of head follows the Utility Syntax Guidelines. The -n option was added to this new interface so that head and tail would be more logically related. Earlier versions of this standard allowed a -number option. This form is no longer specified by this standard but may be present in some implementations.
There is no -c option (as there is in tail) because it is not historical practice and because other utilities in this volume of IEEE Std 1003.1-200x provide similar functionality.

## FUTURE DIRECTIONS

None.
SEE ALSO
sed, tail

## CHANGE HISTORY

First released in Issue 4.
Issue 6
The obsolescent-number form is withdrawn.
The normative text is reworded to avoid use of the term "must" for application requirements.
The DESCRIPTION is updated to clarify that when a file contains less than the number of lines requested, the entire file is copied to standard output.

Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
iconv - codeset conversion

## SYNOPSIS

```
iconv [-cs] -f frommap -t tomap [file...]
iconv -f fromcode [-cs] [-t tocode] [file...]
iconv -t tocode [-cs] [-f fromcode] [file...]
iconv -l
```

## DESCRIPTION

The iconv utility shall convert the encoding of characters in file from one codeset to another and write the results to standard output.
When the options indicate that charmap files are used to specify the codesets (see OPTIONS), the codeset conversion shall be accomplished by performing a logical join on the symbolic character names in the two charmaps. The implementation need not support the use of charmap files for codeset conversion unless the POSIX2_LOCALEDEF symbol is defined on the system.

## OPTIONS

The iconv utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-c Omit any characters that are invalid in the codeset of the input file from the output. When -c is not used, the results of encountering invalid characters in the input stream (either those that are not characters in the codeset of the input file or that have no corresponding character in the codeset of the output file) shall be specified in the system documentation. The presence or absence of -c shall not affect the exit status of iconv.
-f fromcodeset
Identify the codeset of the input file. The implementation shall recognize the following two forms of the fromcodeset option-argument:
fromcode The fromcode option-argument must not contain a slash character. It shall be interpreted as the name of one of the codeset descriptions provided by the implementation in an unspecified format. Valid values of fromcode are implementation-defined.
The frommap option-argument must contain a slash character. It shall be interpreted as the pathname of a charmap file as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File. If the pathname does not represent a valid, readable charmap file, the results are undefined.

If this option is omitted, the codeset of the current locale shall be used.
-1 Write all supported fromcode and tocode values to standard output in an unspecified format.
-s Suppress any messages written to standard error concerning invalid characters. When -s is not used, the results of encountering invalid characters in the input stream (either those that are not valid characters in the codeset of the input file or that have no corresponding character in the codeset of the output file) shall be specified in the system documentation. The presence or absence of $-\mathbf{s}$ shall not
affect the exit status of iconv.
-t tocodeset Identify the codeset to be used for the output file. The implementation shall recognize the following two forms of the tocodeset option-argument:
tocode The semantics shall be equivalent to the $-\mathbf{f}$ fromcode option.
tomap The semantics shall be equivalent to the tomap option.
If this option is omitted, the codeset of the current locale shall be used.
If either $-\mathbf{f}$ or $-\mathbf{t}$ represents a charmap file, but the other does not (or is omitted), or both $-\mathbf{f}$ and $-\mathbf{t}$ are omitted, the results are undefined.

## OPERANDS

The following operand shall be supported:
file A pathname of an input file. If no file operands are specified, or if a file operand is ' $\quad$ ', the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified, or if a file operand is ' ${ }^{\prime}$.

## INPUT FILES

The input file shall be a text file.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of iconv:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments). During translation of the file, this variable is superseded by the use of the fromcode option-argument.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

When the -1 option is used, the standard output shall contain all supported fromcode and tocode values, written in an unspecified format.

When the -1 option is not used, the standard output shall contain the sequence of characters read from the input files, translated to the specified codeset. Nothing else shall be written to the standard output.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The user must ensure that both charmap files use the same symbolic names for characters the two codesets have in common.

## EXAMPLES

The following example converts the contents of file mail.x400 from the ISO/IEC 6937: 2001 standard codeset to the ISO/IEC 8859-1:1998 standard codeset, and stores the results in file mail.local:
iconv -f IS6937 -t IS8859 mail.x400 > mail.local

## RATIONALE

The iconv utility can be used portably only when the user provides two charmap files as optionarguments. This is because a single charmap provided by the user cannot reliably be joined with the names in a system-provided character set description. The valid values for fromcode and tocode are implementation-defined and do not have to have any relation to the charmap mechanisms. As an aid to interactive users, the -1 option was adopted from the Plan 9 operating system. It writes information concerning these implementation-defined values. The format is unspecified because there are many possible useful formats that could be chosen, such as a matrix of valid combinations of fromcode and tocode. The -1 option is not intended for shell script usage; conforming applications will have to use charmaps.

## FUTURE DIRECTIONS

None.

| 19908 |  | LANG | Provide a default value for the internationalization variables that are unset or null. |
| :---: | :---: | :---: | :---: |
| 19909 |  |  | (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, |
| 19910 |  |  | Internationalization Variables for the precedence of internationalization variables |
| 19911 |  |  | used to determine the values of locale categories.) |
| 19912 19913 |  | LC_ALL | If set to a non-empty string value, override the values of all the other internationalization variables. |
| 19914 |  | LC_CTYPE | Determine the locale for the interpretation of sequences of bytes of text data as |
| 19915 |  |  | characters (for example, single-byte as opposed to multi-byte characters in |
| 19916 |  |  | arguments). |
| 19917 |  | LC_MESSAGES |  |
| 19918 |  |  | Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output. |
| 19919 |  |  |  |
| 19920 |  |  |  |
| 19921 | XSI | NLSPATH | Determine the location of message catalogs for the processing of LC_MESSAGES. |

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

The following formats shall be used when the LC_MESSAGES locale category specifies the POSIX locale. In other locales, the strings uid, gid, euid, egid, and groups may be replaced with more appropriate strings corresponding to the locale.

```
"uid=%u(%s) gid=%u(%s)\n", <real user ID>, <user-name>,
    <real group ID>, <group-name>
```

If the effective and real user IDs do not match, the following shall be inserted immediately before the ' $\backslash \mathrm{n}^{\prime}$ character in the previous format:

```
" euid=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<effective user ID>, <effective user-name>
```

If the effective and real group IDs do not match, the following shall be inserted directly before the ${ }^{\prime} \backslash n^{\prime}$ character in the format string (and after any addition resulting from the effective and real user IDs not matching):
" egid=\%u(\%s)"
with the following arguments added at the end of the argument list:

```
<effective group-ID>, <effective group name>
```

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first shall be added directly before the <newline> in the format string:

```
" groups=%u(%s)"
```

with the following arguments added at the end of the argument list:
<supplementary group ID>, <supplementary group name>
and the necessary number of the following added after that for any remaining supplementary group IDs:
", \%u(\%s)"
and the necessary number of the following arguments added at the end of the argument list:

```
<supplementary group ID>, <supplementary group name>
```

If any of the user ID, group ID, effective user ID, effective group ID, or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding " (\%s)" and name argument shall be omitted from the corresponding format string.

When any of the options are specified, the output format shall be as described in the OPTIONS section.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Output produced by the -G option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups. (On systems with user and group IDs that are 32-bit integers and with group names with a maximum of 8 bytes per name, 93 supplementary groups plus distinct effective and real group and user IDs could theoretically overflow the 2048-byte \{LINE_MAX\} text file line limit on the default output case. It would take about 186 supplementary groups to overflow the 2048 -byte barrier using id -G). This is not expected to be a problem in practice, but in cases where it is a concern, applications should consider using fold -s before postprocessing the output of $i d$.

## EXAMPLES

None.

## RATIONALE

The functionality provided by the 4 BSD groups utility can be simulated using:
id -Gn [ user]
The 4 BSD command groups was considered, but it was not included because it did not provide the functionality of the id utility of the SVID. Also, it was thought that it would be easier to modify id to provide the additional functionality necessary to systems with multiple groups than to invent another command.

The options $-\mathbf{u},-\mathbf{g},-\mathbf{n}$, and $-\mathbf{r}$ were added to ease the use of $i d$ with shell commands substitution. Without these options it is necessary to use some preprocessor such as sed to select the desired piece of information. Since output such as that produced by:

```
id -u -n
```

is frequently wanted, it seemed desirable to add the options.

## CHANGE HISTORY

First released in Issue 5.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

ipcs - report XSI interprocess communication facilities status

## SYNOPSIS

xSI ipcs [-qms] [-a|-bcopt]

## DESCRIPTION

The ipcs utility shall write information about active interprocess communication facilities.
Without options, information shall be written in short format for message queues, shared memory segments, and semaphore sets that are currently active in the system. Otherwise, the information that is displayed is controlled by the options specified.

## OPTIONS

The ipcs facility supports the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The ipcs utility accepts the following options:
$-\mathbf{q} \quad$ Write information about active message queues.
-m Write information about active shared memory segments.
-s Write information about active semaphore sets.
If $-\mathbf{q},-\mathbf{m}$, or $-\mathbf{s}$ are specified, only information about those facilities shall be written. If none of these three are specified, information about all three shall be written subject to the following options:
-a Use all print options. (This is a shorthand notation for $-\mathbf{b},-\mathbf{c},-\mathbf{o},-\mathbf{p}$, and $-\mathbf{t}$.)
-b Write information on maximum allowable size. (Maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores.)
-c Write creator's user name and group name; see below.
-o Write information on outstanding usage. (Number of messages on queue and total number of bytes in messages on queue for message queues, and number of processes attached to shared memory segments.)
-p Write process number information. (Process ID of the last process to send a message and process ID of the last process to receive a message on message queues, process ID of the creating process, and process ID of the last process to attach or detach on shared memory segments.)
-t Write time information. (Time of the last control operation that changed the access permissions for all facilities, time of the last $m \operatorname{sgsnd}()$ and $m \operatorname{sgrcv}()$ operations on message queues, time of the last shmat() and shmdt() operations on shared memory, and time of the last semop () operation on semaphores.)

## OPERANDS

None.

## STDIN

Not used.

## INPUT FILES

- The group database
- The user database

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $i p c s$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions voull.dull.

shall cause the corresponding column to appear; "all" means that the column shall always appear. Each column is separated by one or more <space>s. Note that these options only determine what information is provided for each report; they do not determine which reports are written.

T (all) Type of facility:
q Message queue.
m Shared memory segment.
s Semaphore.
This field is a single character written using the format \%c.
ID (all) The identifier for the facility entry. This field shall be written using the format \%d.

KEY (all) The key used as an argument to msgget (), semget (), or shmget () to create the facility entry.

Note: The key of a shared memory segment is changed to IPC_PRIVATE when the segment has been removed until all processes attached to the segment detach it.

This field shall be written using the format $0 x \% x$.
MODE (all) The facility access modes and flags. The mode shall consist of 11 characters that are interpreted as follows.
The first character shall be:
$S \quad$ If a process is waiting on a msgsnd () operation.
If the above is not true.
The second character shall be:
$R \quad$ If a process is waiting on a msgrcv() operation.
C or - If the associated shared memory segment is to be cleared when the first attach operation is executed.
If none of the above is true.
The next nine characters shall be interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the usergroup of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is a minus sign $\left({ }^{\prime}-^{\prime}\right)$.

The permissions shall be indicated as follows:
$r \quad$ If read permission is granted.
$w \quad$ If write permission is granted.
$a \quad$ If alter permission is granted.

- If the indicated permission is not granted.

The first character following the permissions specifies if there is an alternate or additional access control method associated with the facility. If there is no alternate or additional access control method associated with the facility, a single <space> shall be written; otherwise, another printable character is written.

OWNER (all) The user name of the owner of the facility entry. If the user name of the owner is found in the user database, at least the first eight column positions of the name shall be written using the format \%s. Otherwise, the user ID of the owner shall be written using the format \%d.

GROUP (all) The group name of the owner of the facility entry. If the group name of the owner is found in the group database, at least the first eight column positions of the name shall be written using the format \%s. Otherwise, the group ID of the owner shall be written using the format \% d .
The following nine columns shall be only written out for message queues:
CREATOR ( $\mathbf{a}, \mathbf{c}$ ) The user name of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format \%s. Otherwise, the user ID of the creator shall be written using the format $\% \mathrm{~d}$.
CGROUP ( $\mathbf{a}, \mathbf{c}$ ) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format \%s. Otherwise, the group ID of the creator shall be written using the format $\%$ d.
CBYTES ( $\mathbf{a}, \mathbf{o}$ ) The number of bytes in messages currently outstanding on the associated message queue. This field shall be written using the format $\% \mathrm{~d}$.
QNUM ( $\mathbf{a}, \mathbf{o}$ ) The number of messages currently outstanding on the associated message queue. This field shall be written using the format $\% \mathrm{~d}$.
QBYTES ( $\mathbf{a}, \mathbf{b}$ ) The maximum number of bytes allowed in messages outstanding on the associated message queue. This field shall be written using the format \% d.
LSPID ( $\mathbf{a}, \mathbf{p}$ ) The process ID of the last process to send a message to the associated queue. This field shall be written using the format:
"\%d", <pid>
where $\langle$ pid $\rangle$ is 0 if no message has been sent to the corresponding message queue, otherwise, <pid> shall be the process ID of the last process to send a message to the queue.
$\operatorname{LRPID}(\mathbf{a}, \mathbf{p}) \quad$ The process ID of the last process to receive a message from the associated queue. This field shall be written using the format:
"\%d", <pid>
where <pid> is 0 if no message has been received from the corresponding message queue; otherwise, <pid> shall be the process ID of the last process to receive a message from the queue.
$\operatorname{STIME}(\mathbf{a}, \mathbf{t}) \quad$ The time the last message was sent to the associated queue. If a message has been sent to the corresponding message queue, the hour, minute, and second

CREATOR ( $\mathbf{a}, \mathbf{c}$ ) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format \%s. Otherwise, the user ID of the creator shall be written using the format $\% \mathrm{~d}$.

CGROUP $(\mathbf{a}, \mathbf{c})$ The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format $\%$ s. Otherwise, the group ID of the creator shall be written using the format $\% \mathrm{~d}$.

NATTCH ( $\mathbf{a}, \mathbf{o}$ ) The number of processes attached to the associated shared memory segment. This field shall be written using the format \% d.

SEGSZ ( $\mathbf{a}, \mathbf{b}$ ) The size of the associated shared memory segment. This field shall be written using the format $\% \mathrm{~d}$.
CPID ( $\mathbf{a}, \mathbf{p}$ ) The process ID of the creator of the shared memory entry. This field shall be written using the format $\% \mathrm{~d}$.

LPID ( $\mathbf{a}, \mathbf{p}$ ) The process ID of the last process to attach or detach the shared memory segment. This field shall be written using the format:
"\%d", <pid>
where <pid> is 0 if no process has attached the corresponding shared memory segment; otherwise, <pid> shall be the process ID of the last process to attach or detach the segment.
ATIME ( $\mathbf{a}, \mathbf{t}$ ) The time the last attach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been attached, the hour, minute, and second of the last time the segment was attached shall be written using the format $\% \mathrm{~d}: \% 2.2 \mathrm{~d}: \% 2.2 \mathrm{~d}$. Otherwise, the format " no-entry" shall be written.

DTIME ( $\mathbf{a}, \mathbf{t}$ ) The time the last detach on the associated shared memory segment was completed. If the corresponding shared memory segment has ever been detached, the hour, minute, and second of the last time the segment was detached shall be written using the format $\% \mathrm{~d}: \% 2.2 \mathrm{~d}: \% 2.2 \mathrm{~d}$. Otherwise, the format " no-entry" shall be written.

The following four columns shall be only written out for semaphore sets:
CREATOR ( $\mathbf{a}, \mathbf{c}$ ) The user of the creator of the facility entry. If the user name of the creator is found in the user database, at least the first eight column positions of the name shall be written using the format $\% s$. Otherwise, the user ID of the creator shall be written using the format \% d.
CGROUP ( $\mathbf{a}, \mathbf{c}$ ) The group name of the creator of the facility entry. If the group name of the creator is found in the group database, at least the first eight column positions of the name shall be written using the format \%s. Otherwise, the group ID of the creator shall be written using the format \%d.

NSEMS ( $\mathbf{a}, \mathbf{b}$ ) The number of semaphores in the set associated with the semaphore entry. This field shall be written using the format $\% \mathrm{~d}$.

OTIME ( $\mathbf{a}, \mathbf{t}$ ) The time the last semaphore operation on the set associated with the semaphore entry was completed. If a semaphore operation has ever been performed on the corresponding semaphore set, the hour, minute, and second of the last semaphore operation on the semaphore set shall be written using the format $\% \mathrm{~d}: \% 2.2 \mathrm{~d}: \% 2.2 \mathrm{~d}$. Otherwise, the format " no-entry" shall be written.

The following column shall be written for all three reports when it is requested:
CTIME ( $\mathbf{a}, \mathbf{t}$ ) The time the associated entry was created or changed. The hour, minute, and second of the time when the associated entry was created shall be written using the format $\% \mathrm{~d}: \% 2.2 \mathrm{~d}: \% 2.2 \mathrm{~d}$.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
jobs - display status of jobs in the current session

## SYNOPSIS

up jobs [-1|-p] [job_id...]

## DESCRIPTION

The jobs utility shall display the status of jobs that were started in the current shell environment; see Section 2.12 (on page 61).
When jobs reports the termination status of a job, the shell shall remove its process ID from the list of those "known in the current shell execution environment"; see Section 2.9.3.1 (on page 50).

## OPTIONS

The jobs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-l (The letter ell.) Provide more information about each job listed. This information shall include the job number, current job, process group ID, state, and the command that formed the job.
-p Display only the process IDs for the process group leaders of the selected jobs.
By default, the jobs utility shall display the status of all stopped jobs, running background jobs and all jobs whose status has changed and have not been reported by the shell.

## OPERANDS

The following operand shall be supported:
job_id Specifies the jobs for which the status is to be displayed. If no job_id is given, the status information for all jobs shall be displayed. The format of job_id is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID.

## STDIN

Not used.

## INPUT FILES

None.

## LC_MESSAGES

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xSi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

If the $\mathbf{- p}$ option is specified, the output shall consist of one line for each process ID:
"\%d\n", <process ID>
Otherwise, if the -1 option is not specified, the output shall be a series of lines of the form:
" [\%d] \%c \%s \%s\n", <job-number>, <current>, <state>, <command>
where the fields shall be as follows:
<current> The character ' ${ }^{\prime}$ ' identifies the job that would be used as a default for the $f g$ or $b g$ utilities; this job can also be specified using the job_id \%+ or $\% \% \%$ ". The character ' - ' identifies the job that would become the default if the current default job were to exit; this job can also be specified using the job_id \%-. For other jobs, this field is a <space>. At most one job can be identified with ' + ' and at most one job can be identified with ' $\mathbf{'}^{\prime}$. If there is any suspended job, then the current job shall be a suspended job. If there are at least two suspended jobs, then the previous job also shall be a suspended job.
<job-number> A number that can be used to identify the process group to the wait, $f g$, $b g$, and kill utilities. Using these utilities, the job can be identified by prefixing the job number with' ${ }^{\circ}$ ' .
<state> One of the following strings (in the POSIX locale):
Running Indicates that the job has not been suspended by a signal and has not exited.

Done Indicates that the job completed and returned exit status zero.
Done(code) Indicates that the job completed normally and that it exited with the specified non-zero exit status, code, expressed as a decimal number.
Stopped Indicates that the job was suspended by the SIGTSTP signal.
Stopped (SIGTSTP)
Indicates that the job was suspended by the SIGTSTP signal.
Stopped (SIGSTOP)
Indicates that the job was suspended by the SIGSTOP signal.
Stopped (SIGTTIN)
Indicates that the job was suspended by the SIGTTIN signal.
Stopped (SIGTTOU)
Indicates that the job was suspended by the SIGTTOU signal.
The implementation may substitute the string Suspended in place of Stopped. If the job was terminated by a signal, the format of <state> is unspecified, but it shall be visibly distinct from all of the other <state> formats shown here and shall indicate the name or description of the signal causing the termination.
<command> The associated command that was given to the shell.
If the -1 option is specified, a field containing the process group ID shall be inserted before the <state> field. Also, more processes in a process group may be output on separate lines, using only the process ID and <command> fields.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The -p option is the only portable way to find out the process group of a job because different implementations have different strategies for defining the process group of the job. Usage such as $\$(j o b s-\mathbf{p})$ provides a way of referring to the process group of the job in an implementationindependent way.
The jobs utility does not work as expected when it is operating in its own utility execution environment because that environment has no applicable jobs to manipulate. See the APPLICATION USAGE section for bg . For this reason, jobs is generally implemented as a shell regular built-in.

## EXAMPLES

None.
RATIONALE
Both " $\%$ " " and $\%+$ " are used to refer to the current job. Both forms are of equal validity-the " \% \% " mirroring "\$\$" and "\%+" mirroring the output of jobs. Both forms reflect historical practice of the KornShell and the $C$ shell with job control.
The job control features provided by $b g, f g$, and jobs are based on the KornShell. The standard developers examined the characteristics of the C shell versions of these utilities and found that differences exist. Despite widespread use of the C shell, the KornShell versions were selected for this volume of IEEE Std 1003.1-200x to maintain a degree of uniformity with the rest of the KornShell features selected (such as the very popular command line editing features).
The jobs utility is not dependent on the job control option, as are the seemingly related $b g$ and $f g$ utilities because jobs is useful for examining background jobs, regardless of the condition of job control. When the user has invoked a set $+\mathbf{m}$ command and job control has been turned off, $j o b s$ can still be used to examine the background jobs associated with that current session. Similarly, kill can then be used to kill background jobs with kill\% <background job number>.
The output for terminated jobs is left unspecified to accommodate various historical systems. The following formats have been witnessed:

1. Killed(signal name)
2. signal name
3. signal name(coredump)
4. signal description-core dumped

Most users should be able to understand these formats, although it means that applications have trouble parsing them.

The calculation of job IDs was not described since this would suggest an implementation, which may impose unnecessary restrictions.

In an early proposal, a -n option was included to "Display the status of jobs that have changed, exited, or stopped since the last status report". It was removed because the shell always writes any changed status of jobs before each prompt.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Section 2.12 (on page 61), bg, fg, kill, wait

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The JC shading is removed as job control is mandatory in this issue.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
join - relational database operator

## SYNOPSIS

$$
\begin{aligned}
& \text { join [-a file_number|-v file_number] [-e string] [-o list] [-t char] } \\
& \text { [-1 field] [-2 field] file1 file2 }
\end{aligned}
$$

## DESCRIPTION

The join utility shall perform an equality join on the files file1 and file2. The joined files shall be written to the standard output.
The join field is a field in each file on which the files are compared. The join utility shall write one line in the output for each pair of lines in file1 and file2 that have identical join fields. The output line by default shall consist of the join field, then the remaining fields from file1, then the remaining fields from file2. This format can be changed by using the -o option (see below). The -a option can be used to add unmatched lines to the output. The $-\mathbf{v}$ option can be used to output only unmatched lines.
The files file1 and file2 shall be ordered in the collating sequence of sort $\mathbf{- b}$ on the fields on which they shall be joined, by default the first in each line. All selected output shall be written in the same collating sequence.
The default input field separators shall be <blank>s. In this case, multiple separators shall count as one field separator, and leading separators shall be ignored. The default output field separator shall be a <space>.
The field separator and collating sequence can be changed by using the $-\boldsymbol{t}$ option (see below).
If the same key appears more than once in either file, all combinations of the set of remaining fields in file1 and the set of remaining fields in file2 are output in the order of the lines encountered.

If the input files are not in the appropriate collating sequence, the results are unspecified.

## OPTIONS

The join utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a file_number
Produce a line for each unpairable line in file file_number, where file_number is 1 or 2 , in addition to the default output. If both -a 1 and -a 2 are specified, all unpairable lines shall be output.
-e string Replace empty output fields in the list selected by -o with the string string.
-o list Construct the output line to comprise the fields specified in list, each element of which shall have one of the following two forms:

1. file_number.field, where file_number is a file number and field is a decimal integer field number
2. 0 (zero), representing the join field

The elements of list shall be either comma-separated or <blank>-separated, as specified in Guideline 8 of the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. The fields specified by list shall be written for all selected output lines. Fields selected by list that do not appear in the input shall be treated as empty output fields. (See the -e option.) Only specifically
requested fields shall be written. The application shall ensure that list is a single command line argument.
-t char Use character char as a separator, for both input and output. Every appearance of char in a line shall be significant. When this option is specified, the collating sequence shall be the same as sort without the -b option.
-v file_number
Instead of the default output, produce a line only for each unpairable line in file_number, where file_number is 1 or 2 . If both $-\mathbf{v} 1$ and $-\mathbf{v} 2$ are specified, all unpairable lines shall be output.
-1 field Join on the fieldth field of file 1. Fields are decimal integers starting with 1.
$\mathbf{- 2}$ field Join on the fieldth field of file 2. Fields are decimal integers starting with 1.

## OPERANDS

The following operands shall be supported:
file1, file2 A pathname of a file to be joined. If either of the file1 or file2 operands is ${ }^{\prime} \mathbf{~}^{\prime}$, the standard input shall be used in its place.

## STDIN

The standard input shall be used only if the file1 or file 2 operand is ${ }^{\prime} \mathbf{~}^{\prime}$. See the INPUT FILES section.

## INPUT FILES

The input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of join:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale of the collating sequence join expects to have been used when the input files were sorted.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The join utility output shall be a concatenation of selected character fields. When the $-\mathbf{o}$ option is not specified, the output shall be:

```
"%s%s%s\n", <join field>, <other filel fields>,
    <other file2 fields>
```

If the join field is not the first field in a file, the <other file fields> for that file shall be:

```
<fields preceding join field>, <fields following join field>
```

When the -o option is specified, the output format shall be:
"\%s n ", <concatenation of fields>
where the concatenation of fields is described by the -o option, above.
For either format, each field (except the last) shall be written with its trailing separator character. If the separator is the default (<blank>s), a single <space> shall be written after each field (except the last).

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were output successfully.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Pathnames consisting of numeric digits or of the form string.string should not be specified directly following the $-\mathbf{o}$ list.

## EXAMPLES

The -0 field essentially selects the union of the join fields. For example, given file phone:

| ! Name | Phone Number |
| :--- | :--- |
| Don | +1 |
| Hal | $123-456-7890$ |
| Yasushi | +1 |
| 1234-567-8901 |  |
|  | +2 |

and file fax:

| ! Name | Fax Number |
| :--- | :--- |
| Don | +1 123-456-7899 |
| Keith | $+1456-789-0122$ |
| Yasushi | $+2345-678-9011$ |

(where the large expanses of white space are meant to each represent a single <tab>), the command:
join -t "<tab>" -a 1 -a 2 -e '(unknown)' -o 0,1.2,2.2 phone fax
would produce:

| $!$ Name | Phone Number | Fax Number |
| :--- | :--- | :--- |
| Don | $+1123-456-7890$ | $+1123-456-7899$ |
| Hal | $+1234-567-8901$ | (unknown) |
| Keith | (unknown) | $+1456-789-0122$ |
| Yasushi | $+2345-678-9012$ | $+2345-678-9011$ |

Multiple instances of the same key will produce combinatorial results. The following:

```
fa:
    a x
    a y
    a z
fb:
    a p
```

will produce:
a $x p$
a y p
a z p
And the following:

## fa:

a b c
a de
fb:
a w x
a y z
a ○ p
will produce:
a b c w x
a b c y z
a b c o p
a de w x
a dey z
a deop

## RATIONALE

The -e option is only effective when used with -o because, unless specific fields are identified using -o, join is not aware of what fields might be empty. The exception to this is the join field, but identifying an empty join field with the e string is not historical practice and some scripts might break if this were changed.
The 0 field in the -o list was adopted from the Tenth Edition version of join to satisfy international objections that the join in the base documents does not support the "full join" or "outer join" described in relational database literature. Although it has been possible to include a join field in the output (by default, or by field number using -o), the join field could not be included for an unpaired line selected by -a. The -o 0 field essentially selects the union of the join fields.
files was considered to be the end of the file; the description in this volume of IEEE Std 1003.1-200x does not cite this as an allowable case.

Earlier versions of this standard allowed $-\mathbf{j},-\mathbf{j} 1,-\mathbf{j} 2$ options, and a form of the $-\mathbf{o}$ option that allowed the list option-argument to be multiple arguments. These forms are no longer specified by this standard but may be present in some implementations.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The obsolescent -j options and the multi-argument -o option are withdrawn in this issue.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME kill - terminate or signal processes

## SYNOPSIS

XSI

```
kill -s signal_name pid...
kill -l [exit_status]
kill [-signal_name] pid...
kill [-signal_number] pid...
```

## DESCRIPTION

The kill utility shall send a signal to the process or processes specified by each pid operand.
For each pid operand, the kill utility shall perform actions equivalent to the kill() function defined in the System Interfaces volume of IEEE Std 1003.1-200x called with the following arguments:

- The value of the pid operand shall be used as the pid argument.
- The sig argument is the value specified by the -s option, -signal_number option, or the -signal_name option, or by SIGTERM, if none of these options is specified.

## OPTIONS

The kill utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section
12.2, Utility Syntax Guidelines, except that in the last two SYNOPSIS forms, the -signal_number and -signal_name options are usually more than a single character.
The following options shall be supported:
-1 (The letter ell.) Write all values of signal_name supported by the implementation, if no operand is given. If an exit_status operand is given and it is a value of the '?' shell special parameter (see Section 2.5 .2 and wait) corresponding to a process that was terminated by a signal, the signal_name corresponding to the signal that terminated the process shall be written. If an exit_status operand is given and it is the unsigned decimal integer value of a signal number, the signal_name (the symbolic constant name without the SIG prefix defined in the Base Definitions volume of IEEE Std 1003.1-200x) corresponding to that signal shall be written. Otherwise, the results are unspecified.
-s signal_name
Specify the signal to send, using one of the symbolic names defined in the <signal.h> header. Values of signal_name shall be recognized in a case-independent fashion, without the SIG prefix. In addition, the symbolic name 0 shall be recognized, representing the signal value zero. The corresponding signal shall be sent instead of SIGTERM.

## -signal_name

Equivalent to -s signal_name.

## -signal_number

Specify a non-negative decimal integer, signal_number, representing the signal to be used instead of SIGTERM, as the sig argument in the effective call to kill(). The correspondence between integer values and the sig value used is shown in the following list.
The effects of specifying any signal_number other than those listed below are
undefined.
00
1 SIGHUP
2 SIGINT
3 SIGQUIT
6 SIGABRT
9 SIGKILL
14 SIGALRM

## 15 SIGTERM

If the first argument is a negative integer, it shall be interpreted as a -signal_number option, not as a negative pid operand specifying a process group.

## OPERANDS

The following operands shall be supported:
pid One of the following:

1. A decimal integer specifying a process or process group to be signaled. The process or processes selected by positive, negative, and zero values of the pid operand shall be as described for the kill() function. If process number 0 is specified, all processes in the current process group shall be signaled. For the effects of negative pid numbers, see the kill() f

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

When the -1 option is not specified, the standard output shall not be used.
When the -1 option is specified, the symbolic name of each signal shall be written in the following format:
"\%s\%c", <signal_name>, <separator>
where the <signal_name> is in uppercase, without the SIG prefix, and the <separator> shall be either a <newline> or a <space>. For the last signal written, <separator> shall be a <newline>.

When both the -1 option and exit_status operand are specified, the symbolic name of the corresponding signal shall be written in the following format:
"\%s\n", <signal_name>

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 At least one matching process was found for each pid operand, and the specified signal was successfully processed for at least one matching process.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Process numbers can be found by using $p s$.
The job control job ID notation is not required to work as expected when kill is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &
system("kill %1");
```

the kill operates in a different environment and does not share the shell's understanding of job numbers.

## EXAMPLES

Any of the commands:

```
kill -9 100 -165
kill -s kill 100 -165
kill -s KILL 100 -165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose
process group ID is 165 , assuming the sending process has permission to send that signal to the specified processes, and that they exist.
The System Interfaces volume of IEEE Std 1003.1-200x and this volume of IEEE Std 1003.1-200x do not require specific signal numbers for any signal_names. Even the -signal_number option provides symbolic (although numeric) names for signals. If a process is terminated by a signal, its exit status indicates the signal that killed it, but the exact values are not specified. The kill -1 option, however, can be used to map decimal signal numbers and exit status values into the name of a signal. The following example reports the status of a terminated job:

```
job
stat=$?
if [ $stat -eq 0 ]
then
    echo job completed successfully.
elif [ $stat -gt 128 ]
then
            echo job terminated by signal SIG$(kill -l $stat).
else
            echo job terminated with error code $stat.
fi
```

To send the default signal to a process group (say 123), an application should use a command similar to one of the following:

```
kill -TERM -123
kill -- -123
```

## RATIONALE

The -1 option originated from the C shell, and is also implemented in the KornShell. The C shell output can consist of multiple output lines because the signal names do not always fit on a single line on some terminal screens. The KornShell output also included the implementationdefined signal numbers and was considered by the standard developers to be too difficult for scripts to parse conveniently. The specified output format is intended not only to accommodate the historical $C$ shell output, but also to permit an entirely vertical or entirely horizontal listing on systems for which this is appropriate.

An early proposal invented the name SIGNULL as a signal_name for signal 0 (used by the System Interfaces volume of IEEE Std 1003.1-200x to test for the existence of a process without sending it a signal). Since the signal_name 0 can be used in this case unambiguously, SIGNULL has been removed.

An early proposal also required symbolic signal_names to be recognized with or without the SIG prefix. Historical versions of kill have not written the SIG prefix for the -1 option and have not recognized the SIG prefix on signal_names. Since neither applications portability nor ease-of-use would be improved by requiring this extension, it is no longer required.
To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, IEEE Std 1003.1-200x mandates that it is always considered the former by implementations that support the XSI option. It also requires that conforming applications always use the "--" options terminator argument when specifying a process group, unless an option is also specified.
The -s option was added in response to international interest in providing some form of kill that meets the Utility Syntax Guidelines.
The job control job ID notation is not required to work as expected when kill is operating in its own utility execution environment. In either of the following examples:
nohup kill \%1 \&

```
system("kill %1");
```

the kill operates in a different environment and does not understand how the shell has managed its job numbers.

## FUTURE DIRECTIONS

None.

Chapter 2 (on page 29), ps, wait, the System Interfaces volume of IEEE Std 1003.1-200x, kill(), the Base Definitions volume of IEEE Std 1003.1-200x, <signal.h>

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The obsolescent versions of the SYNOPSIS are turned into non-obsolescent features of the XSI option, corresponding to a similar change in the trap special built-in.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

lex - generate programs for lexical tasks (DEVELOPMENT)

## SYNOPSIS

CD lex [-t] [-n|-v] [file...]

## DESCRIPTION

The lex utility shall generate C programs to be used in lexical processing of character input, and that can be used as an interface to yacc. The C programs shall be generated from lex source code and conform to the ISO C standard. Usually, the lex utility shall write the program it generates to the file lex.yy.c; the state of this file is unspecified if lex exits with a non-zero exit status. See the EXTENDED DESCRIPTION section for a complete description of the lex input language.

## OPTIONS

The lex utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for Guideline 9.

The following options shall be supported:

| -n | Suppress the summary of statistics usually written with the $-\mathbf{v}$ option. If no table sizes are specified in the lex source code and the $-\mathbf{v}$ option is not specified, then $-\mathbf{n}$ is implied. |
| :---: | :---: |
| -t | Write the resulting program to standard output instead of lex.yy.c. |
| -v | Write a summary of lex statistics to the standard output. (See the discussion of lex table sizes in Definitions in lex (on page 537).) If the $-\mathbf{t}$ option is specified and $-\mathbf{n}$ is not specified, this report shall be written to standard error. If table sizes are specified in the lex source code, and if the $-\mathbf{n}$ option is not specified, the $-\mathbf{v}$ option may be enabled. |

## OPERANDS

The following operand shall be supported:
file A pathname of an input file. If more than one such file is specified, all files shall be concatenated to produce a single lex program. If no file operands are specified, or if a file operand is ' - ', the standard input shall be used.

## STDIN

The standard input shall be used if no file operands are specified, or if a file operand is ' - '. See INPUT FILES.

## INPUT FILES

The input files shall be text files containing lex source code, as described in the EXTENDED DESCRIPTION section.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of lex:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions. If this variable is not set to the POSIX locale, the results are unspecified.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes within regular expressions. If this variable is not set to the POSIX locale, the results are unspecified.

## LC_MESSAGES

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If the -t option is specified, the text file of $C$ source code output of lex shall be written to standard output.

If the $-\mathbf{t}$ option is not specified:

- Implementation-defined informational, error, and warning messages concerning the contents of lex source code input shall be written to either the standard output or standard error.
- If the $-\mathbf{v}$ option is specified and the $-\mathbf{n}$ option is not specified, lex statistics shall also be written to either the standard output or standard error, in an implementation-defined format. These statistics may also be generated if table sizes are specified with a '\%' operator in the Definitions section, as long as the $-\mathbf{n}$ option is not specified.

## STDERR

If the $-\mathbf{t}$ option is specified, implementation-defined informational, error, and warning messages concerning the contents of lex source code input shall be written to the standard error.

If the $-\mathbf{t}$ option is not specified:

1. Implementation-defined informational, error, and warning messages concerning the contents of lex source code input shall be written to either the standard output or standard error.
2. If the $-\mathbf{v}$ option is specified and the $-\mathbf{n}$ option is not specified, lex statistics shall also be written to either the standard output or standard error, in an implementation-defined format. These statistics may also be generated if table sizes are specified with a ' $\%$ ' operator in the Definitions section, as long as the $-\mathbf{n}$ option is not specified.

## OUTPUT FILES

A text file containing $C$ source code shall be written to lex.yy.c, or to the standard output if the $-\mathbf{t}$ option is present.

## EXTENDED DESCRIPTION

Each input file shall contain lex source code, which is a table of regular expressions with corresponding actions in the form of $C$ program fragments.
When lex.yy.c is compiled and linked with the lex library (using the -11 operand with c99), the resulting program shall read character input from the standard input and shall partition it into strings that match the given expressions.

When an expression is matched, these actions shall occur:

- The input string that was matched shall be left in yytext as a null-terminated string; yytext shall either be an external character array or a pointer to a character string. As explained in Definitions in lex (on page 537), the type can be explicitly selected using the \%array or \%pointer declarations, but the default is implementation-defined.
- The external int yyleng shall be set to the length of the matching string.
- The expression's corresponding program fragment, or action, shall be executed.

During pattern matching, lex shall search the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first shall be chosen.

The general format of lex source shall be:

## Definitions

\% \%
Rules
\% \%
UserSubroutines

The first $" \% \%$ is required to mark the beginning of the rules (regular expressions and actions); the second $" \% \%$ " is required only if user subroutines follow.

Any line in the Definitions section beginning with a <blank> shall be assumed to be a C program fragment and shall be copied to the external definition area of the lex.yy.c file. Similarly, anything in the Definitions section included between delimiter lines containing only "\% \{" and "\% \} " shall also be copied unchanged to the external definition area of the lex.yy.c file.
Any such input (beginning with a <blank> or within "\% $\{$ " and "\% " "delimiter lines) appearing at the beginning of the Rules section before any rules are specified shall be written to lex.yy.c after the declarations of variables for the yylex () function and before the first line of code in yylex (). Thus, user variables local to yylex () can be declared here, as well as application code to execute upon entry to yylex ().

The action taken by lex when encountering any input beginning with a <blank> or within "\% \{" and "\%\}" delimiter lines appearing in the Rules section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the yylex () function.

## Definitions in lex

Definitions appear before the first $\% \% \%$ delimiter. Any line in this section not contained between "\%\{" and "\%\}" lines and not beginning with a <blank> shall be assumed to define a lex substitution string. The format of these lines shall be:
name substitute
If a name does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string substitute shall replace the string \{name\} when it is used in a rule. The name string shall be recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.
In the Definitions section, any line beginning with $\mathrm{a}^{\prime} \circ^{\prime \prime}$ (percent sign) character and followed by an alphanumeric word beginning with either ' $s$ ' or ${ }^{\prime} S$ ' shall define a set of start conditions. Any line beginning with $a^{\prime} \%$ ' followed by a word beginning with either ' x ' or ${ }^{\prime} \mathrm{X}$ ' shall define a set of exclusive start conditions. When the generated scanner is in a $\% s$ state, patterns with no state specified shall be also active; in a $\% \mathrm{x}$ state, such patterns shall not be active. The rest of the line, after the first word, shall be considered to be one or more <blank>-separated
names of start conditions. Start condition names shall be constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in Regular Expressions in lex (on page 539).
Implementations shall accept either of the following two mutually-exclusive declarations in the Definitions section:
\%array Declare the type of yytext to be a null-terminated character array.
\%pointer Declare the type of yytext to be a pointer to a null-terminated character string.
The default type of yytext is implementation-defined. If an application refers to yytext outside of the scanner source file (that is, via an extern), the application shall include the appropriate \%array or \%pointer declaration in the scanner source file.
Implementations shall accept declarations in the Definitions section for setting certain internal table sizes. The declarations are shown in the following table.

Table 4-9 Table Size Declarations in lex

| Declaration | Description | Minimum Value |
| :--- | :--- | :---: |
| $\% \mathbf{p} n$ | Number of positions | 2500 |
| $\% \mathbf{n} n$ | Number of states | 500 |
| $\% \mathbf{a} n$ | Number of transitions | 2000 |
| $\% \mathbf{e} n$ | Number of parse tree nodes | 1000 |
| $\% \mathbf{k} n$ | Number of packed character classes | 1000 |
| $\% \mathbf{0} n$ | Size of the output array | 3000 |

In the table, $n$ represents a positive decimal integer, preceded by one or more <blank>s. The exact meaning of these table size numbers is implementation-defined. The implementation shall document how these numbers affect the lex utility and how they are related to any output that may be generated by the implementation should limitations be encountered during the execution of lex. It shall be possible to determine from this output which of the table size values needs to be modified to permit lex to successfully generate tables for the input language. The values in the column Minimum Value represent the lowest values conforming implementations shall provide.

## Rules in lex

The rules in lex source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.

ERE action
ERE action

The extended regular expression (ERE) portion of a row shall be separated from action by one or more <blank>s. A regular expression containing <blank>s shall be recognized under one of the following conditions:

- The entire expression appears within double-quotes.
- The <blank>s appear within double-quotes or square brackets.
- Each <blank> is preceded by a backslash character.

## User Subroutines in lex

Anything in the user subroutines section shall be copied to lex.yy.c following yylex ().

## Regular Expressions in lex

The lex utility shall support the set of extended regular expressions (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions), with the following additions and exceptions to the syntax:
"..." Any string enclosed in double-quotes shall represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) shall be recognized. Any backslash-escape sequence shall be terminated by the closing quote. For example, "\01""1" represents a single string: the octal value 1 followed by the character ' 1 '.
<state>r, <state1,state2,...>r
The regular expression $r$ shall be matched only when the program is in one of the start conditions indicated by state, state1, and so on; see Actions in lex (on page 541). (As an exception to the typographical conventions of the rest of this volume of IEEE Std 1003.1-200x, in this case <state> does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition shall be recognized as such only at the beginning of a regular expression.
$r / x \quad$ The regular expression $r$ shall be matched only if it is followed by an occurrence of regular expression $x$ ( $x$ is the instance of trailing context, further defined below). The token returned in yytext shall only match $r$. If the trailing portion of $r$ matches the beginning of $x$, the result is unspecified. The $r$ expression cannot include further trailing context or the ' $\$$ ' (match-end-of-line) operator; $x$ cannot include the ' $n$ ' (match-beginning-of-line) operator, nor trailing context, nor the '\$' operator. That is, only one occurrence of trailing context is allowed in a lex regular expression, and the operator only can be used at the beginning of such an expression.
\{name\} When name is one of the substitution symbols from the Definitions section, the string, including the enclosing braces, shall be replaced by the substitute value. The substitute value shall be treated in the extended regular expression as if it were enclosed in parentheses. No substitution shall occur if \{name\} occurs within a bracket expression or within double-quotes.
Within an ERE, a backslash character shall be considered to begin an escape sequence as specified in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File
 sequences in the following table shall be recognized.
A literal <newline> cannot occur within an ERE; the escape sequence ${ }^{\prime} \backslash n^{\prime}$ can be used to represent a <newline>. A <newline> shall not be matched by a period operator.

Table 4-10 Escape Sequences in lex

| Escape Sequence | Description | Meaning |
| :---: | :---: | :---: |
| $\backslash$ digits | A backslash character followed by the longest sequence of one, two, or three octal-digit characters (01234567). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined. | The character whose encoding is represented by the one, two, or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading ${ }^{\prime} \backslash$ ' for each byte. |
| \xdigits | A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0 (that is, representation of the NUL character), the behavior is undefined. | The character whose encoding is represented by the hexadecimal integer. |
| \c | A backslash character followed by any character not described in this table or in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation ( ${ }^{\prime} \backslash \backslash^{\prime}$, <br> $\prime \backslash \mathrm{a}^{\prime},{ }^{\prime} \backslash \mathrm{b}^{\prime}, \backslash \mathrm{f}^{\prime}{ }^{\prime} \backslash \mathrm{n}^{\prime},{ }^{\prime} \backslash \mathrm{r}^{\prime}$, <br> $\left.{ }^{\prime} \backslash t^{\prime}, \prime \backslash v^{\prime}\right)$. | The character ' $c$ ', unchanged. |

Note: If a ' $\backslash x^{\prime}$ sequence needs to be immediately followed by a hexadecimal digit character, a sequence such as "\x1""1" can be used, which represents a character containing the value 1 , followed by the character ' 1 '.
The order of precedence given to extended regular expressions for lex differs from that specified in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.4, Extended Regular Expressions. The order of precedence for lex shall be as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true operators. The start condition, trailing context, and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

Table 4-11 ERE Precedence in lex

| Extended Regular Expression | Precedence |
| :---: | :---: |
| collation-related bracket symbols | [= =] [: : ] [. .] |
| escaped characters | \<special character> |
| bracket expression | [ ] |
| quoting | ". . . $"$ |
| grouping | ( ) |
| definition | \{ name \} |
| single-character RE duplication concatenation | * + ? |
| interval expression | $\{\mathrm{m}, \mathrm{n}\}$ |
| alternation |  |

The ERE anchoring operators ' $\times$ ' and ' $\$$ ' do not appear in the table. With lex regular expressions, these operators are restricted in their use: the ${ }^{\prime \prime}$ ' operator can only be used at the beginning of an entire regular expression, and the ' $\$$ ' operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern " (^abc) |(def\$)" is undefined; it can instead be written as two separate rules, one with the regular expression "^abc" and one with "def\$", which share a common action via the special $\left.\right|^{\prime}$ action (see below). If the pattern were written "^abc|def\$", it would match either "abc" or "def" on a line by itself.
Unlike the general ERE rules, embedded anchoring is not allowed by most historical lex implementations. An example of embedded anchoring would be for patterns such as $"(\wedge \mid) f o o(\mid \$) "$ to match $" f \circ \circ "$ when it exists as a complete word. This functionality can be obtained using existing lex features:

Note also that ' $\$$ ' is a form of trailing context (it is equivalent to " $/ \backslash \mathrm{n}$ ") and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).
The additional regular expressions trailing-context operator '/' can be used as an ordinary character if presented within double-quotes, " $\ell$ "; preceded by a backslash, " $\backslash / /$ "; or within a bracket expression, " [/]". The start-condition ' $\langle$ ' and ' $>$ ' operators shall be special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they shall be treated as ordinary characters.

## Actions in lex

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement ' ; ' shall be a valid action; any string in the lex.yy.c input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action shall not be valid, and the action lex takes in such a condition is undefined.
The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
program statement }
```

The default action when a string in the input to a lex.yy.c program is not matched by any expression shall be to copy the string to the output. Because the default behavior of a program
generated by lex is to read the input and copy it to the output, a minimal lex source program that has just $\% \%$ " shall generate a C program that simply copies the input to the output unchanged.
Four special actions shall be available:
ECHO; REJECT; BEGIN
$\mid \quad$ The action ${ }^{\prime} \mid$ ' means that the action for the next rule is the action for this rule. Unlike the other three actions, ' $\left.\right|^{\prime}$ cannot be enclosed in braces or be semicolonterminated; the application shall ensure that it is specified alone, with no other actions.

ECHO; Write the contents of the string yytext on the output.
REJECT; Usually only a single expression is matched by a given string in the input. REJECT means "continue to the next expression that matches the current input", and shall cause whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions "xyz" and "xy" and the input "xyz", usually only the regular expression "xyz" would match. The next attempted match would start after $\mathbf{z}$. If the last action in the "xyz" rule is REJECT, both this rule and the "xy" rule would be executed. The REJECT action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a goto to another part of yylex (). The use of REJECT may result in somewhat larger and slower scanners.
BEGIN The action:
BEGIN newstate;
switches the state (start condition) to nerustate. If the string newstate has not been declared previously as a start condition in the Definitions section, the results are unspecified. The initial state is indicated by the digit ' 0 ' or the token INITIAL.
The functions or macros described below are accessible to user code included in the lex input. It is unspecified whether they appear in the C code output of lex, or are accessible only through the $-\mathbf{1 1}$ operand to c99 (the lex library).

## int yylex(void)

Performs lexical analysis on the input; this is the primary function generated by the lex utility. The function shall return zero when the end of input is reached; otherwise, it shall return non-zero values (tokens) determined by the actions that are selected.

## int yymore(void)

When called, indicates that when the next input string is recognized, it is to be appended to the current value of yytext rather than replacing it; the value in yyleng shall be adjusted accordingly.

## int yyless(int $n$ )

Retains $n$ initial characters in yytext, NUL-terminated, and treats the remaining characters as if they had not been read; the value in yyleng shall be adjusted accordingly.

## int input(void)

Returns the next character from the input, or zero on end-of-file. It shall obtain input from the stream pointer yyin, although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of yyin is undefined. The character read shall be removed from the input stream of the scanner without any processing by the scanner.
int unput(int c)
Returns the character ' c ' to the input; yytext and yyleng are undefined until the next expression is matched. The result of using unput () for more characters than have been input is unspecified.
The following functions shall appear only in the lex library accessible through the -11 operand; they can therefore be redefined by a conforming application:

## int yywrap(void)

Called by yylex () at end-of-file; the default yywrap() shall always return 1. If the application requires yylex () to continue processing with another source of input, then the application can include a function yywrap(), which associates another file with the external variable FILE * yyin and shall return a value of zero.
int main(int $\arg c$, char $* \operatorname{argv}[])$
Calls yylex() to perform lexical analysis, then exits. The user code can contain main() to perform application-specific operations, calling yylex() as applicable.
Except for input(), unput(), and main(), all external and static names generated by lex shall begin with the prefix yy or $\mathbf{Y Y}$.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Conforming applications are warned that in the Rules section, an ERE without an action is not acceptable, but need not be detected as erroneous by lex. This may result in compilation or runtime errors.
The purpose of input () is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.
The lex utility is not fully internationalized in its treatment of regular expressions in the lex source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the lex source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current lex technology. Furthermore, the very nature of the lexical analyzers produced by lex must be closely tied to the lexical requirements of the input language being described, which is frequently locale-specific anyway. (For example, writing an analyzer that is used for French text is not automatically useful for processing other languages.)

## EXAMPLES

The following is an example of a lex program that implements a rudimentary scanner for a Pascal-like syntax:

ㅇ $\{$
/* Need this for the call to atof() below. */
\#include <math.h>
/* Need this for printf(), fopen(), and stdin below. */
\#include <stdio.h>
ㅇ)
DIGIT [0-9]

```
ID [a-z][a-z0-9]*
%%
{DIGIT}+ {
        printf("An integer: %s (%d)\n", yytext,
            atoi(yytext));
        }
{DIGIT}+"."{DIGIT}* {
    printf("A float: %s (%g)\n", yytext,
        atof(yytext));
    }
if|then|begin|end|procedure|function {
    printf("A keyword: %s\n", yytext);
    }
```

\{ID\} printf("An identifier: \%s ${ }^{\text {n", yytext); }}$
"+"|"-"|"*"|"/" printf("An operator: \%s m ", yytext);
"\{"[^\}\n]*"\}" /* Eat up one-line comments. */
[ \t\n]+ /* Eat up white space. *V
. printf("Unrecognized character: \%s\n", yytext);
$\% \%$
int main(int argc, char *argv[])
\{
++argv, --argc; /* Skip over program name. */
if (argc > 0)
yyin $=$ fopen (argv[0], rr");
else
yyin $=$ stdin;
yylex ();
\}

## RATIONALE

Even though the -coption and references to the $C$ language are retained in this description, lex may be generalized to other languages, as was done at one time for EFL, the Extended FORTRAN Language. Since the lex input specification is essentially language-independent, versions of this utility could be written to produce Ada, Modula-2, or Pascal code, and there are known historical implementations that do so.
The current description of lex bypasses the issue of dealing with internationalized EREs in the lex source code or generated lexical analyzer. If it follows the model used by awk (the source code is assumed to be presented in the POSIX locale, but input and output are in the locale specified by the environment variables), then the tables in the lexical analyzer produced by lex would interpret EREs specified in the lex source in terms of the environment variables specified when lex was executed. The desired effect would be to have the lexical analyzer interpret the EREs given in the lex source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current lex technology.
The description of octal and hexadecimal-digit escape sequences agrees with the ISO C standard use of escape sequences.
Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

There is no detailed output format specification. The observed behavior of lex under four different historical implementations was that none of these implementations consistently reported the line numbers for error and warning messages. Furthermore, there was a desire that lex be allowed to output additional diagnostic messages. Leaving message formats unspecified avoids these formatting questions and problems with internationalization.
Although the $\% \mathrm{x}$ specifier for exclusive start conditions is not historical practice, it is believed to be a minor change to historical implementations and greatly enhances the usability of lex programs since it permits an application to obtain the expected functionality with fewer statements.

The \%array and \%pointer declarations were added as a compromise between historical systems. The System V-based lex copies the matched text to a yytext array. The flex program, supported in BSD and GNU systems, uses a pointer. In the latter case, significant performance improvements are available for some scanners. Most historical programs should require no change in porting from one system to another because the string being referenced is null-terminated in both cases. (The method used by flex in its case is to null-terminate the token in place by remembering the character that used to come right after the token and replacing it before continuing on to the next scan.) Multi-file programs with external references to yytext outside the scanner source file should continue to operate on their historical systems, but would require one of the new declarations to be considered strictly portable.

The description of EREs avoids unnecessary duplication of ERE details because their meanings within a lex ERE are the same as that for the ERE in this volume of IEEE Std 1003.1-200x.

The reason for the undefined condition associated with text beginning with a <blank> or within $" \%\{$ " and "\%\}" delimiter lines appearing in the Rules section is historical practice. Both the BSD and System V lex copy the indented (or enclosed) input in the Rules section (except at the beginning) to unreachable areas of the yylex () function (the code is written directly after a break statement). In some cases, the System V lex generates an error message or a syntax error, depending on the form of indented input.
The intention in breaking the list of functions into those that may appear in lex.yy.c versus those that only appear in libl.a is that only those functions in libl.a can be reliably redefined by a conforming application.

The descriptions of standard output and standard error are somewhat complicated because historical lex implementations chose to issue diagnostic messages to standard output (unless -t was given). IEEE Std 1003.1-200x allows this behavior, but leaves an opening for the more expected behavior of using standard error for diagnostics. Also, the System V behavior of writing the statistics when any table sizes are given is allowed, while BSD-derived systems can avoid it. The programmer can always precisely obtain the desired results by using either the $-\mathbf{t}$ or -n options.
The OPERANDS section does not mention the use of - as a synonym for standard input; not all historical implementations support such usage for any of the file operands.
A description of the translation table was deleted from early proposals because of its relatively low usage in historical applications.
The change to the definition of the input() function that allows buffering of input presents the opportunity for major performance gains in some applications.
The following examples clarify the differences between lex regular expressions and regular expressions appearing elsewhere in this volume of IEEE Std 1003.1-200x. For regular expressions of the form " $r / x$ ", the string matching $r$ is always returned; confusion may arise when the beginning of $x$ matches the trailing portion of $r$. For example, given the regular expression " $\mathrm{a} \star \mathrm{b} / \mathrm{cc}$ " and the input "aaabcc", yytext would contain the string "aaab" on this match. But given the regular expression " $x * / x y$ " and the input "xxxy", the token $\mathbf{x x x}$, not $\mathbf{x x}$, is returned
by some implementations because $\mathbf{x x x}$ matches " x *".
In the rule " $\mathrm{ab} * / \mathrm{bc}$ ", the " $\mathrm{b} *$ " at the end of $r$ extends $r$ 's match into the beginning of the trailing context, so the result is unspecified. If this rule were " $\mathrm{ab} / \mathrm{bc}$ ", however, the rule matches the text " ab " when it is followed by the text " bc ". In this latter case, the matching of $r$ cannot extend into the beginning of $x$, so the result is specified.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as part of the C-Language Development Utilities option.
The obsolescent -c option is removed.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/14 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7
SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

```
NAME
link - call \(\operatorname{link}()\) function
```

## SYNOPSIS

```
xSI link file1 file2
```

## DESCRIPTION

```
The link utility shall perform the function call:
link(file1, file2);
A user may need appropriate privilege to invoke the link utility.
```

## OPTIONS

```
None.
OPERANDS
The following operands shall be supported:
file1 The pathname of an existing file.
file2 The pathname of the new directory entry to be created.
```

## STDIN

```
Not used.
```

## INPUT FILES

```
Not used.
```

## ENVIRONMENT VARIABLES

```
The following environment variables shall affect the execution of link:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
```

## ASYNCHRONOUS EVENTS

```
Default.
```

## STDOUT

```
None.
```

STDERR
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.
EXTENDED DESCRIPTION
None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## SEE ALSO

ln, unlink, the System Interfaces volume of IEEE Std 1003.1-200x, $\operatorname{link}()$

## CHANGE HISTORY

First released in Issue 5.

## NAME

$\ln$ — link files

## SYNOPSIS

ln [-fs] source_file target_file
ln [-fs] source_file... target_dir

## DESCRIPTION

In the first synopsis form, the $\ln$ utility shall create a new directory entry (link) at the destination path specified by the target_file operand. If the -s option is specified, a symbolic link shall be created for the file specified by the source_file operand. This first synopsis form shall be assumed when the final operand does not name an existing directory; if more than two operands are specified and the final is not an existing directory, an error shall result.
In the second synopsis form, the ln utility shall create a new directory entry (link), or if the $-\mathbf{s}$ option is specified a symbolic link, for each file specified by a source_file operand, at a destination path in the existing directory named by target_dir.

If the last operand specifies an existing file of a type not specified by the System Interfaces volume of IEEE Std 1003.1-200x, the behavior is implementation-defined.
The corresponding destination path for each source_file shall be the concatenation of the target directory pathname, a slash character, and the last pathname component of the source_file. The second synopsis form shall be assumed when the final operand names an existing directory.
For each source_file:

1. If the destination path exists:
a. If the $-\mathbf{f}$ option is not specified, $\ln$ shall write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source-files.
b. Actions shall be performed equivalent to the unlink() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called using destination as the path argument. If this fails for any reason, in shall write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source_files.
2. If the -s option is specified, In shall create a symbolic link named by the destination path and containing as its pathname source_file. The ln utility shall do nothing more with source_file and shall go on to any remaining files.
3. If source_file is a symbolic link, actions shall be performed equivalent to the link() function using the object that source_file references as the path1 argument and the destination path as the path2 argument. The ln utility shall do nothing more with source_file and shall go on to any remaining files.
4. Actions shall be performed equivalent to the $\operatorname{link}()$ function defined in the System Interfaces volume of IEEE Std 1003.1-200x using source_file as the path1 argument, and the destination path as the path2 argument.

## OPTIONS

The ln utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following option shall be supported:

$$
\begin{array}{ll}
\text {-f } & \text { Force existing destination pathnames to be removed to allow the link. } \\
\text {-s } & \text { Create symbolic links instead of hard links. }
\end{array}
$$

```

\section*{OPERANDS}
```

The following operands shall be supported:
source_file A pathname of a file to be linked. If the -s option is specified, no restrictions on the type of file or on its existence shall be made. If the -s option is not specified, whether a directory can be linked is implementation-defined.
target_file The pathname of the new directory entry to be created.
target_dir A pathname of an existing directory in which the new directory entries are created.

```

\section*{STDIN}
```

Not used.

```

\section*{INPUT FILES}

\section*{RATIONALE}

The CONSEQUENCES OF ERRORS section does not require \(l n-\mathbf{f} a b\) to remove \(b\) if a subsequent link operation would fail.
Some historic versions of \(l n\) (including the one specified by the SVID) unlink the destination file, if it exists, by default. If the mode does not permit writing, these versions prompt for confirmation before attempting the unlink. In these versions the \(-\mathbf{f}\) option causes \(\ln\) not to attempt to prompt for confirmation.
This allows \(l n\) to succeed in creating links when the target file already exists, even if the file itself is not writable (although the directory must be). Early proposals specified this functionality.
This volume of IEEE Std 1003.1-200x does not allow the ln utility to unlink existing destination paths by default for the following reasons:
- The \(\ln\) utility has historically been used to provide locking for shell applications, a usage that is incompatible with \(l n\) unlinking the destination path by default. There was no corresponding technical advantage to addíng this functionality.
- This functionality gave \(\ln\) the ability to destroy the link structure of files, which changes the historical behavior of \(\ln\).
- This functionality is easily replicated with a combination of \(r m\) and \(\ln\).
- It is not historical practice in many systems; BSD and BSD-derived systems do not support this behavior. Unfortunately, whichever behavior is selected can cause scripts written expecting the other behavior to fail.
- It is preferable that ln perform in the same manner as the \(\operatorname{link}()\) function, which does not permit the target to exist already.
This volume of IEEE Std 1003.1-200x retains the -f option to provide support for shell scripts depending on the SVID semantics. It seems likely that shell scripts would not be written to handle prompting by \(\ln\) and would therefore have specified the -f option.
The -f option is an undocumented feature of many historical versions of the ln utility, allowing linking to directories. These versions require modification.
Early proposals of this volume of IEEE Std 1003.1-200x also required a -i option, which behaved like the \(-\mathbf{i}\) options in \(c p\) and \(m v\), prompting for confirmation before unlinking existing files. This was not historical practice for the \(\ln\) utility and has been omitted.

chmod, find, pax, rm, the System Interfaces volume of IEEE Std 1003.1-200x, \(\operatorname{link}(), \operatorname{unlink}()\)

\section*{CHANGE HISTORY}

First released in Issue 2.

Issue 6
The \(\ln\) utility is updated to include symbolic link processing as defined in the IEEE P1003.2b draft standard.

Issue 7
SD5-XCU-ERN-27 is applied, adding a new paragraph to the RATIONALE.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

\section*{NAME}
locale - get locale-specific information

\section*{SYNOPSIS}
```

locale [-a |-m]
locale [-ck] name...

```

\section*{DESCRIPTION}

The locale utility shall write information about the current locale environment, or all public locales, to the standard output. For the purposes of this section, a public locale is one provided by the implementation that is accessible to the application.
When locale is invoked without any arguments, it shall summarize the current locale environment for each locale category as determined by the settings of the environment variables defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale.
When invoked with operands, it shall write values that have been assigned to the keywords in the locale categories, as follows:
- Specifying a keyword name shall select the named keyword and the category containing that keyword.
- Specifying a category name shall select the named category and all keywords in that category.

\section*{OPTIONS}

The locale utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a Write information about all available public locales. The available locales shall include POSIX, representing the POSIX locale. The manner in which the
implementation determines what other locales are available is implementation-
defined.
Write the names of selected locale categories; see the STDOUT section. The -c
option increases readability when more than one category is selected (for example,
via more than one keyword name or via a category name). It is valid both with
and without the -k option.
Write the names and values of selected keywords. The implementation may omit
values for some keywords; see the OPERANDS section.
-k \(\quad\) Write names of available charmaps; see the Base Definitions volume of
-m \(\quad\) IEEE Std 1003.1-200x, Section 6.1, Portable Character Set.

\section*{OPERANDS}

The following operand shall be supported:
name The name of a locale category as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale, the name of a keyword in a locale category, or the reserved name charmap. The named category or keyword shall be selected for output. If a single name repr

\section*{STDIN}

Not used.

\section*{INPUT FILES}

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of locale:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

\section*{LC_MESSAGES}

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
The application shall ensure that the LANG, LC_*, and NLSPATH environment variables specify the current locale environment to be written out; they shall be used if the -a option is not specified.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The LANG variable shall be written first using the format:
```

"LANG=%s\n", <value>

```

If LANG is not set or is an empty string, the value is the empty string.
If locale is invoked without any options or operands, the names and values of the LC_* environment variables described in this volume of IEEE Std 1003.1-200x shall be written to the standard output, one variable per line, and each line using the following format. Only those variables set in the environment and not overridden by LC_ALL shall be written using this format:
```

"%s=%s\n", <variable_name>, <value>

```

The names of those LC_* variables associated with locale categories defined in this volume of IEEE Std 1003.1-200x that are not set in the environment or are overridden by LC_ALL shall be written in the following format:
"\%s=\"\%s\"\n", <variable_name>, <implied value>
The <implied value> shall be the name of the locale that has been selected for that category by the implementation, based on the values in \(L A N G\) and \(L C \_A L L\), as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.
The <value> and <implied value> shown above shall be properly quoted for possible later reentry to the shell. The <value> shall not be quoted using double-quotes (so that it can be distinguished by the user from the <implied value> case, which always requires double-quotes).
The \(L C \_A L L\) variable shall be written last, using the first format shown above. If it is not set, it
shall be written as:
"LC_ALL=\n"
If any arguments are specified:
1. If the -a option is specified, the names of all the public locales shall be written, each in the following format:
"\%s\n", <locale name>
2. If the -c option is specified, the names of all selected categories shall be written, each in the following format:
"\%s n ", <category name>
If keywords are also selected for writing (see following items), the category name output shall precede the keyword output for that category.
If the -c option is not specified, the names of the categories shall not be written; only the keywords, as selected by the <name> operand, shall be written.
3. If the \(-\mathbf{k}\) option is specified, the names and values of selected keywords shall be written. If a value is non-numeric and is not a compound keyword value, it shall be written in the following format:
"\%s=\"\%s\"\n", <keyword name>, <keyword value>
If a value is a non-numeric compound keyword value, it shall either be written in the format:
"\%s=\"\%s\"\n", <keyword name>, <keyword value>
where the <keyword value> is a single string of values separated by semicolons, or it shall be written in the format:
"\%s=\%s \n", <keyword name>, <keyword value>
where the <keyword value> is encoded as a set of strings, each enclosed in doublequotation marks, separated by semicolons.
If the keyword was charmap, the name of the charmap (if any) that was specified via the localedef \(-\mathbf{f}\) option when the locale was created shall be written, with the word charmap as <keyword name>.
If a value is numeric, it shall be written in one of the following formats:
"\%s=\%d\n", <keyword name>, <keyword value>
"\%s=\%c\%o\n", <keyword name>, <escape character>, <keyword value>
"\%s=\%cx\%x\n", <keyword name>, <escape character>, <keyword value>
where the <escape character> is that identified by the escape_char keyword in the current locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3, Locale Definition.

Compound keyword values (list entries) shall be separated in the output by semicolons. When included in keyword values, the semicolon, the double-quote, the backslash, and any control character shall be preceded (escaped) with the escape character.
4. If the \(-\mathbf{k}\) option is not specified, selected keyword values shall be written, each in the following format:
```

"%s\n", <keyword value>

```

If the keyword was charmap, the name of the charmap (if any) that was specified via the
localedef -f option when the locale was created shall be written.
5. If the \(-\mathbf{m}\) option is specified, then a list of all available charmaps shall be written, each in the format:
"\%s\n", <charmap>
where <charmap> is in a format suitable for use as the option-argument to the localedef \(-\mathbf{f}\) option.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 All the requested information was found and output successfully.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

If the LANG environment variable is not set or set to an empty value, or one of the LC_* environment variables is set to an unrecognized value, the actual locales assumed (if any) are implementation-defined as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.
Implementations are not required to write out the actual values for keywords in the categories LC_CTYPE and LC_COLLATE; however, they must write out the categories (allowing an application to determine, for example, which character classes are available).

\section*{EXAMPLES}

In the following examples, the assumption is that locale environment variables are set as follows:
```

LANG=locale_x
LC_COLLATE=locale_Y

```

The command locale would result in the following output:
```

LANG=locale_x
LC_CTYPE="locale_x"
LC_COLLATE=locale_Y
LC_TIME="locale_x"
LC_NUMERIC="locale_x"
LC_MONETARY="locale_x"
LC_MESSAGES="locale_x"
LC_ALL=

```

The order of presentation of the categories is not specified by this volume of IEEE Std 1003.1-200x.
The command:
LC_ALL=POSIX locale -ck decimal_point
would produce:
```

LC_NUMERIC

```
decimal_point="."

The following command shows an application of locale to determine whether a user-supplied response is affirmative:
```

if printf "%s\n" "$response" | grep -Eq "$(locale yesexpr)"
then
affirmative processing goes here
else
non-affirmative processing goes here
fi

```

\section*{RATIONALE}

The output for categories LC_CTYPE and LC_COLLATE has been made implementation-defined because there is a questionable value in having a shell script receive an entire array of characters. It is also difficult to return a logical collation description, short of returning a complete localedef source.

The \(-\mathbf{m}\) option was included to allow applications to query for the existence of charmaps. The output is a list of the charmaps (implementation-supplied and user-supplied, if any) on the system.
The -c option was included for readability when more than one category is selected (for example, via more than one keyword name or via a category name). It is valid both with and without the -k option.
The charmap keyword, which returns the name of the charmap (if any) that was used when the current locale was created, was included to allow applications needing the information to retrieve it.

\section*{FUTURE DIRECTIONS}

\section*{NAME}
localedef - define locale environment

\section*{SYNOPSIS}
```

localedef [-c] [-f charmap] [-i sourcefile] [-u code_set_name] name

```

\section*{DESCRIPTION}

The localedef utility shall convert source definitions for locale categories into a format usable by the functions and utilities whose operational behavior is determined by the setting of the locale environment variables defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale. It is implementation-defined whether users have the capability to create new locales, in addition to those supplied by the implementation. If the symbolic constant XSI POSIX2_LOCALEDEF is defined, the system supports the creation of new locales. On XSIconformant systems, the symbolic constant POSIX2_LOCALEDEF shall be defined.

The utility shall read source definitions for one or more locale categories belonging to the same locale from the file named in the -i option (if specified) or from standard input.

The name operand identifies the target locale. The utility shall support the creation of public, or generally accessible locales, as well as private, or restricted-access locales. Implementations may restrict the capability to create or modify public locales to users with the appropriate privileges.

Each category source definition shall be identified by the corresponding environment variable name and terminated by an END category-name statement. The following categories shall be supported. In addition, the input may contain source for implementation-defined categories.
LC_CTYPE Defines character classification and case conversion.
LC_COLLATE
Defines collation rules.
LC_MONETARY
Defines the format and symbols used in formatting of monetary information.
LC_NUMERIC
Defines the decimal delimiter, grouping, and grouping symbol for non-monetary numeric editing.

LC_TIME Defines the format and content of date and time information.
LC_MESSAGES
Defines the format and values of affirmative and negative responses.

\section*{OPTIONS}

The localedef utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-c Create permanent output even if warning messages have been issued.
-f charmap Specify the pathname of a file containing a mapping of character symbols and collating element symbols to actual character encodings. The format of the charmap is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File. The application shall ensure that this option is specified if symbolic names (other than collating symbols defined in a collating-symbol keyword) are used. If the -f option is not present, an implementation-defined character mapping shall be used.
-i inputfile \(\begin{aligned} & \text { The pathname of a file containing the source definitions. If this option is not } \\ & \text { present, source definitions shall be read from standard input. The format of the } \\ & \text { inputfile is described in the Base Definitions volume of IEEE Std 1003.1-200x, } \\ & \text { Section 7.3, Locale Definition. } \\ & \text {-u code_set_name } \\ & \text { Specify the name of a codeset used as the target mapping of character symbols and } \\ & \text { collating element symbols whose encoding values are defined in terms of the } \\ & \text { ISO/IEC 10646-1:2000 standard position constant values. }\end{aligned}\) l\(l\)

\section*{OPERANDS}

The following operand shall be supported:
name Identifies the locale; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale for a description of the use of this name. If the name contains one or more slash characters, name shall be interpreted as a pathname where the created locale definitions shall be stored. If name does not contain any slash characters, the interpretation of the name is implementation-defined and the locale shall be public. The ability to create public locales in this way may be restricted to users with appropriate privileges. (As a consequence of specifying one name, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

\section*{STDIN}

Unless the -i option is specified, the standard input shall be a text file containing one or more locale category source definitions, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 7.3, Locale Definition. When lines are continued using the escape character mechanism, there is no limit to the length of the accumulated continued line.

\section*{INPUT FILES}

The character set mapping file specified as the charmap option-argument is described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File. If a locale category source definition contains a copy statement, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 7, Locale, and the copy statement names a valid, existing locale, then localedef shall behave as if the source definition had contained a valid category source definition for the named locale.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of localedef:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
(This variable has no affect on localedef; the POSIX locale is used for this category.)
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). This variable has no affect on the processing of localedef input data; the POSIX locale is used for this purpose, regardless of the value of this variable.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The utility shall report all categories successfully processed, in an unspecified format.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

The format of the created output is unspecified. If the name operand does not contain a slash, the existence of an output file for the locale is unspecified.

\section*{EXTENDED DESCRIPTION}

When the -u option is used, the code_set_name option-argument shall be interpreted as an implementation-defined name of a codeset to which the ISO/IEC 10646-1:2000 standard position constant values shall be converted via an implementation-defined method. Both the ISO/IEC 10646-1:2000 standard position constant values and other formats (decimal, hexadecimal, or octal) shall be valid as encoding values within the charmap file. The codeset represented by the implementation-defined name can be any codeset that is supported by the implementation.
When conflicts occur between the charmap specification of <code_set_name>, <mb_cur_max>, or <mb_cur_min> and the implementation-defined interpretation of these respective items for the codeset represented by the -u option-argument code_set_name, the result is unspecified.
When conflicts occur between the charmap encoding values specified for symbolic names of characters of the portable character set and the implementation-defined assignment of character encoding values, the result is unspecified.
If a non-printable character in the charmap has a width specified that is not \(\mathbf{- 1}\), the result will be undefined.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 No errors occurred and the locales were successfully created.
1 Warnings occurred and the locales were successfully created.
2 The locale specification exceeded implementation limits or the coded character set or sets used were not supported by the implementation, and no locale was created.
3 The capability to create new locales is not supported by the implementation.
>3 Warnings or errors occurred and no output was created.

\section*{CONSEQUENCES OF ERRORS}

If an error is detected, no permanent output shall be created.
If warnings occur, permanent output shall be created if the -c option was specified. The following conditions shall cause warning messages to be issued:
- If a symbolic name not found in the charmap file is used for the descriptions of the LC_CTYPE or LC_COLLATE categories (for other categories, this shall be an error condition).
- If the number of operands to the order keyword exceeds the \{COLL_WEIGHTS_MAX\} limit.
- If optional keywords not supported by the implementation are present in the source.

Other implementation-defined conditions may also cause warnings.

\section*{APPLICATION USAGE}

The charmap definition is optional, and is contained outside the locale definition. This allows both completely self-defined source files, and generic sources (applicable to more than one codeset). To aid portability, all charmap definitions must use the same symbolic names for the portable character set. As explained in the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.4, Character Set Description File, it is implementation-defined whether or not users or applications can provide additional character set description files. Therefore, the \(-\mathbf{f}\) option might be operable only when an implementation-defined charmap is named.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The output produced by the localedef utility is implementation-defined. The name operand is used to identify the specific locale. (As a consequence, although several categories can be processed in one execution, only categories belonging to the same locale can be processed.)

\section*{FUTURE DIRECTIONS}

None.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/16 is applied, making the text consistent with the descriptions of WIDTH and WIDTH_DEFAULT in the Base Definitions volume of IEEE Std 1003.1-200x.

\section*{Issue 7}

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
logger - log messages

\section*{SYNOPSIS}
```

    logger string...
    ```

\section*{DESCRIPTION}

The logger utility saves a message, in an unspecified manner and format, containing the string operands provided by the user. The messages are expected to be evaluated later by personnel performing system administration tasks.
It is implementation-defined whether messages written in locales other than the POSIX locale are effective.

\section*{OPTIONS}

None.

\section*{OPERANDS}

The following operand shall be supported:
string \(\quad\) One of the string arguments whose contents are concatenated together, in the order specified, separated by single <space>s.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of logger:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error. (This means diagnostics from logger to the user or application, not diagnostic messages that the user is sending to the system administrator.)

\section*{xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.}

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

Not used.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

Unspecified.

\section*{EXTENDED DESCRIPTION}

\section*{None.}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

This utility allows logging of information for later use by a system administrator or programmer in determining why non-interactive utilities have failed. The locations of the saved messages, their format, and retention period are all unspecified. There is no method for a conforming application to read messages, once written.

\section*{EXAMPLES}

A batch application, running non-interactively, tries to read a configuration file and fails; it may attempt to notify the system administrator with:
logger myname: unable to read file foo. [timestamp]

\section*{RATIONALE}

The standard developers believed strongly that some method of alerting administrators to errors was necessary. The obvious example is a batch utility, running non-interactively, that is unable to read its configuration files or that is unable to create or write its results file. However, the standard developers did not wish to define the format or delivery mechanisms as they have historically been (and will probably continue to be) very system-specific, as well as involving functionality clearly outside the scope of this volume of IEEE Std 1003.1-200x.
The text with \(\angle C \_\)MESSAGES about diagnostic messages means diagnostics from logger to the user or application, not diagnostic messages that the user is sending to the system administrator.
Multiple string arguments are allowed, similar to echo, for ease-of-use.
Like the utilities mailx and lp, logger is admittedly difficult to test. This was not deemed sufficient justification to exclude these utilities from this volume of IEEE Std 1003.1-200x. It is also arguable that they are, in fact, testable, but that the tests themselves are not portable.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
lp, mailx, write

\section*{CHANGE HISTORY}

First released in Issue 4.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
logname - return the user's login name

\section*{SYNOPSIS}
```

    logname
    ```

\section*{DESCRIPTION}

The logname utility shall write the user's login name to standard output. The login name shall be the string that would be returned by the getlogin() function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Under the conditions where the getlogin( ) function would fail, the logname utility shall write a diagnostic message to standard error and exit with a non-zero exit status.

\section*{OPTIONS}

None.

\section*{OPERANDS}

None.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of logname:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
\(L C \_C T Y P E\) Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.
STDOUT
The logname utility output shall be a single line consisting of the user's login name:
"\%s\n", <login name>

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

OUTPUT FILES
None.

\section*{EXTENDED DESCRIPTION}

None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

The logname utility explicitly ignores the LOGNAME environment variable because environment changes could produce erroneous results.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The passwd file is not listed as required because the implementation may have other means of mapping login names.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
id, who, the System Interfaces volume of IEEE Std 1003.1-200x, getlogin()

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{NAME}
lp - send files to a printer

\section*{SYNOPSIS}
lp [-c] [-d dest] [-n copies] [-msw] [-o option]... [-t title] [file...]

\section*{DESCRIPTION}

The \(l p\) utility shall copy the input files to an output destination in an unspecified manner. The default output destination should be to a hardcopy device, such as a printer or microfilm recorder, that produces non-volatile, human-readable documents. If such a device is not available to the application, or if the system provides no such device, the \(l p\) utility shall exit with a non-zero exit status.

The actual writing to the output device may occur some time after the \(l p\) utility successfully exits. During the portion of the writing that corresponds to each input file, the implementation shall guarantee exclusive access to the device.

The \(l p\) utility shall associate a unique request \(I D\) with each request.
Normally, a banner page is produced to separate and identify each print job. This page may be suppressed by implementation-defined conditions, such as an operator command or one of the -o option values.

\section*{OPTIONS}

The \(l p\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-c Exit only after further access to any of the input files is no longer required. The application can then safely delete or modify the files without affecting the output operation. Normally, files are not copied, but are linked whenever possible. If the -c option is not given, then the user should be careful not to remove any of the files before the request has been printed in its entirety. It should also be noted that in the absence of the -c option, any changes made to the named files after the request is made but before it is printed may be reflected in the printed output. On some implementations, -c may be on by default.
-d dest Specify a string that names the destination (dest). If dest is a printer, the request shall be printed only on that specific printer. If dest is a class of printers, the request shall be printed on the first available printer that is a member of the class. Under certain conditions (printer unavailability, file space limitation, and so on), requests for specific destinations need not be accepted. Destination names vary between systems.
If \(-\mathbf{d}\) is not specified, and neither the LPDEST nor PRINTER environment variable is set, an unspecified destination is used. The \(-\mathbf{d}\) dest option shall take precedence over LPDEST, which in turn shall take precedence over PRINTER. Results are undefined when dest contains a value that is not a valid destination name.
\(-\mathbf{m} \quad\) Send mail (see mailx) after the files have been printed. By default, no mail is sent upon normal completion of the print request.
-n copies Write copies number of copies of the files, where copies is a positive decimal integer. The methods for producing multiple copies and for arranging the multiple copies when multiple file operands are used are unspecified, except that each file shall be output as an integral whole, not interleaved with portions of other files.
\begin{tabular}{ll}
22149 & \(-\mathbf{o}\) option \\
22150 & \\
22151 & \(-\mathbf{s}\) \\
22152 & \(-\mathbf{t}\) title \\
22153 & \(-\mathbf{w}\) \\
22154 &
\end{tabular}

Specify printer-dependent or class-dependent options. Several such options may be collected by specifying the -o option more than once.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a file to be output. If no file operands are specified, or if a file operand is \({ }^{\prime}-^{\prime}\), the standard input shall be used. If a file operand is used, but the -c option is not specified, the process performing the writing to the output device may have user and group permissions that differ from that of the process invoking \(l p\).

\section*{STDIN}

The standard input shall be used only if no file operands are specified, or if a file operand is ' \(\mathbf{\prime}^{\prime}\). See the INPUT FILES section.

\section*{INPUT FILES}

The input files shall be text files.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(l p\) :
\(L A N G \quad\) Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L \quad\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LC_TIME Determine the format and contents of date and time strings displayed in the \(l p\) banner page, if any.
LPDEST Determine the destination. If the \(\angle P D E S T\) environment variable is not set, the PRINTER environment variable shall be used. The -d dest option takes precedence over LPDEST. Results are undefined when -d is not specified and LPDEST contains a value that is not a valid destination name.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PRINTER Determine the output device or destination. If the LPDEST and PRINTER environment variables are not set, an unspecified output device is used. The \(-\mathbf{d}\) dest option and the LPDEST environment variable shall take precedence over PRINTER. Results are undefined when \(-\mathbf{d}\) is not specified, LPDEST is unset, and PRINTER contains a value that is not a valid device or destination name.

TZ Determine the timezone used to calculate date and time strings displayed in the \(l p\) banner page, if any. If \(T Z\) is unset or null, an unspecified default timezone shall be used.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The \(l p\) utility shall write a request \(I D\) to the standard output, unless -s is specified. The format of the message is unspecified. The request ID can be used on systems supporting the historical cancel and lpstat utilities.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 All input files were processed successfully.
>0 No output device was available, or an error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

The \(p r\) and fold utilities can be used to achieve reasonable formatting for the implementation's default page size.
A conforming application can use one of the file operands only with the \(-\mathbf{c}\) option or if the file is publicly readable and guaranteed to be available at the time of printing. This is because IEEE Std 1003.1-200x gives the implementation the freedom to queue up the request for printing at some later time by a different process that might not be able to access the file.

\section*{EXAMPLES}
1. To print file file:
lp -c file
2. To print multiple files with headers:
```

pr file1 file2 | lp

```

\section*{RATIONALE}

The \(l p\) utility was designed to be a basic version of a utility that is already available in many historical implementations. The standard developers considered that it should be implementable simply as:
```

cat "\$@" > /dev/lp

```
after appropriate processing of options, if that is how the implementation chose to do it and if exclusive access could be granted (so that two users did not write to the device simultaneously). Although in the future the standard developers may add other options to this utility, it should always be able to execute with no options or operands and send the standard input to an unspecified output device.
This volume of IEEE Std 1003.1-200x makes no representations concerning the format of the
printed output, except that it must be "human-readable" and "non-volatile". Thus, writing by default to a disk or tape drive or a display terminal would not qualify. (Such destinations are not prohibited when -d dest, LPDEST, or PRINTER are used, however.)
This volume of IEEE Std 1003.1-200x is worded such that a "print job" consisting of multiple input files, possibly in multiple copies, is guaranteed to print so that any one file is not intermixed with another, but there is no statement that all the files or copies have to print out together.

The -c option may imply a spooling operation, but this is not required. The utility can be implemented to wait until the printer is ready and then wait until it is finished. Because of that, there is no attempt to define a queuing mechanism (priorities, classes of output, and so on).
On some historical systems, the request ID reported on the STDOUT can be used to later cancel or find the status of a request using utilities not defined in this volume of IEEE Std 1003.1-200x.
Although the historical System V lp and BSD lpr utilities have provided similar functionality, they used different names for the environment variable specifying the destination printer. Since the name of the utility here is \(l p, L P D E S T\) (used by the System \(\mathrm{V} l p\) utility) was given precedence over PRINTER (used by the BSD lpr utility). Since environments of users frequently contain one or the other environment variable, the \(l p\) utility is required to recognize both. If this was not done, many applications would send output to unexpected output devices when users moved from system to system.

Some have commented that \(l p\) has far too little functionality to make it worthwhile. Requests have proposed additional options or operands or both that added functionality. The requests included:
- Wording requiring the output to be "hardcopy"
- A requirement for multiple printers
- Options for supporting various page-description languages

Given that a compliant system is not required to even have a printer, placing further restrictions upon the behavior of the printer is not useful. Since hardcopy format is so applicationdependent, it is difficult, if not impossible, to select a reasonable subset of functionality that should be required on all compliant systems.

The term unspecified is used in this section in lieu of implementation-defined as most known implementations would not be able to make definitive statements in their conformance documents; the existence and usage of printers is very dependent on how the system administrator configures each individual system.
Since the default destination, device type, queuing mechanisms, and acceptable forms of input are all unspecified, usage guidelines for what a conforming application can do are as follows:
- Use the command in a pipeline, or with -c, so that there are no permission problems and the files can be safely deleted or modified.
- Limit output to text files of reasonable line lengths and printable characters and include no device-specific formatting information, such as a page description language. The meaning of "reasonable" in this context can only be answered as a quality-of-implementation issue, but it should be apparent from historical usage patterns in the industry and the locale. The \(p r\) and fold utilities can be used to achieve reasonable formatting for the default page size of the implementation.

Alternatively, the application can arrange its installation in such a way that it requires the system administrator or operator to provide the appropriate information on \(l p\) options and environment variable values.

At a minimum, having this utility in this volume of IEEE Std 1003.1-200x tells the industry that
conforming applications require a means to print output and provides at least a command name and \(L P D E S T\) routing mechanism that can be used for discussions between vendors, application writers, and users. The use of "should" in the DESCRIPTION of \(l p\) clearly shows the intent of the standard developers, even if they cannot mandate that all systems (such as laptops) have printers.

This volume of IEEE Std 1003.1-200x does not specify what the ownership of the process performing the writing to the output device may be. If -c is not used, it is unspecified whether the process performing the writing to the output device has permission to read file if there are any restrictions in place on who may read file until after it is printed. Also, if -c is not used, the results of deleting file before it is printed are unspecified.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
mailx

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- In the DESCRIPTION, the requirement to associate a unique request ID, and the normal generation of a banner page is added.
- In the OPTIONS section.
- The -d dest description is expanded, but references to lpstat are removed.
- The \(-\mathbf{m},-\mathbf{o},-\mathbf{s},-\mathbf{t}\), and \(-\mathbf{w}\) options are added.
- In the ENVIRONMENT VARIABLES section, LC_TIME may now affect the execution.
- The STDOUT section is added.

The normative text is reworded to avoid use of the term "must" for application requirements.
The \(T Z\) entry is added to the ENVIRONMENT VARIABLES section.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

\section*{NAME}
ls - list directory contents

\section*{SYNOPSIS}
xSI ls [-ACFRSacdilmnpqrtul] [-H|-L] [-fgos] [file...]

\section*{DESCRIPTION}

For each operand that names a file of a type other than directory or symbolic link to a directory, \(l s\) shall write the name of the file as well as any requested, associated information. For each operand that names a file of type directory, \(l s\) shall write the names of files contained within the directory as well as any requested, associated information. Filenames beginning with a period \(\left({ }^{\prime} .^{\prime}\right)\) and any associated information shall not be written out unless explicitly referenced, the -A or -a option is supplied, or an implementation-defined condition causes them to be written. If one of the \(-\mathbf{d},-\mathbf{F}\), or \(-\mathbf{l}\) options are specified, and one of the \(-\mathbf{H}\) or \(-\mathbf{L}\) options are not specified, for each operand that names a file of type symbolic link to a directory, \(l s\) shall write the name of the file as well as any requested, associated information. If none of the \(-\mathbf{d},-\mathbf{F}\), or -1 options are specified, or the \(-\mathbf{H}\) or \(-\mathbf{L}\) options are specified, for each operand that names a file of type symbolic link to a directory, ls shall write the names of files contained within the directory as well as any requested, associated information.
If no operands are specified, \(l s\) shall write the contents of the current directory. If more than one operand is specified, \(l\) shall write non-directory operands first; it shall sort directory and nondirectory operands separately according to the collating sequence in the current locale.
The \(l s\) utility shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file encountered. When it detects an infinite loop, \(l\) shall write a diagnostic message to standard error and shall either recover its position in the hierarchy or terminate.

\section*{OPTIONS}

The \(l s\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-A Write out all directory entries, including those whose names begin with a period ( \({ }^{\prime} .{ }^{\prime}\) ) but excluding the entries dot and dot-dot (if they exist).
-C Write multi-text-column output with entries sorted down the columns, according to the collating sequence. The number of text columns and the column separator characters are unspecified, but should be adapted to the nature of the output device.
-F Do not follow symbolic links named as operands unless the \(-\mathbf{H}\) or \(-\mathbf{L}\) options are specified. Write a slash \(\left(\prime^{\prime}\right)\) immediately after each pathname that is a directory, an asterisk \(\left(r^{\prime} *^{\prime}\right)\) after each that is executable, a vertical bar \(\left(\left.\left.\right|^{\prime}\right|^{\prime}\right)\) after each that is a FIFO, and an at sign ( \(\left(^{\prime} @^{\prime}\right)\) after each that is a symbolic link. For other file types, other symbols may be written.
-H If a symbolic link referencing a file of type directory is specified on the command line, \(l s\) shall evaluate the file information and file type to be those of the file referenced by the link, and not the link itself; however, ls shall write the name of the link itself and not the file referenced by the link.
-L Evaluate the file information and file type for all symbolic links (whether named on the command line or encountered in a file hierarchy) to be those of the file referenced by the link, and not the link itself; however, ls shall write the name of the link itself and not the file referenced by the link. When \(-\mathbf{L}\) is used with \(-\mathbf{l}\), write
\begin{tabular}{|c|c|c|c|}
\hline \multicolumn{3}{|l|}{22361} & the contents of symbolic links in the long format (see the STDOUT section). \\
\hline 22362 & & -R & Recursively list subdirectories encountered. \\
\hline 22363 & & -S & Sort with the primary key being file size (in decreasing order) and the secondary \\
\hline \multicolumn{2}{|l|}{22364} & & key being filename in the collating sequence (in increasing order). \\
\hline 22366 & & -a & Write out all directory entries, including those whose names begin with a period ( \({ }^{\prime}\) '). \\
\hline 22367 & & -c & Use time of last modification of the file status information (see <sys/stat.h> in the \\
\hline 22368 & & & System Interfaces volume of IEEE Std 1003.1-200x) instead of last modification of \\
\hline \multicolumn{2}{|l|}{22369} & & the file itself for sorting \((-\mathbf{t})\) or writing \((-\mathbf{1})\). \\
\hline 22370 & & -d & Do not follow symbolic links named as operands unless the \(-\mathbf{H}\) or -L options are \\
\hline 22371 & & & specified. Do not treat directories differently than other types of files. The use of \(-\mathbf{d}\) \\
\hline \multicolumn{2}{|l|}{22372} & & with \(-\mathbf{R}\) produces unspecified results. \\
\hline 22373 & XSI & -f & Force each argument to be interpreted as a directory and list the name found in \\
\hline 22374 & & & each slot. This option shall turn off \(-\mathbf{l},-\mathbf{t},-\mathbf{S},-\mathbf{s}\), and \(-\mathbf{r}\), and shall turn on \(-\mathbf{a}\); the \\
\hline 22375 & & & order is the order in which entries appear in the directory. \\
\hline 22376 & \multirow[t]{3}{*}{XSI} & -g & The same as -1 , except that the owner shall not be written. \\
\hline 22377 & & -i & For each file, write the file's file serial number (see stat () in the System Interfaces \\
\hline 22378 & & & volume of IEEE Std 1003.1-200x). \\
\hline 22379 & & -1 & (The letter ell.) Do not follow symbolic links named as operands unless the \(-\mathbf{H}\) or \\
\hline 22380 & & & -L options are specified. Write out in long format (see the STDOUT section). When \\
\hline 22381 & & & -1 (ell) is specified, -1 (one) shall be assumed. \\
\hline 22382 & & -m & Stream output format; list files across the page, separated by commas. \\
\hline 22383 & & -n & The same as -1 , except that the owner's UID and GID numbers shall be written, \\
\hline 22384 & & & rather than the associated character strings. \\
\hline 22385 & XSI & -0 & The same as -1 , except that the group shall not be written. \\
\hline 22386 & & -p & Write a slash ( \({ }^{\prime} /{ }^{\prime}\) ) after each filename if that file is a directory. \\
\hline 2238 & & \(-\mathrm{q}\) & Force each instance of non-printable filename characters and <tab>s to be written \\
\hline 2238 & & & s the question-mark ( \({ }^{\prime}\) ' ) character. Implementations may provide this option by \\
\hline 2238 & & & default if the output is to a terminal device. \\
\hline 22390 & & -r & Reverse the order of the sort to get reverse collating sequence oldest first, or \\
\hline 2239 & & & smallest file size first depending on the other options given. \\
\hline 22392 & \multirow[t]{2}{*}{XSI} & -s & Indicate the total number of file system blocks consumed by each file displayed. \\
\hline 223 & & & The block size is implementation-defined. \\
\hline 22394 & & -t & Sort with the primary key being time modified (most recently modified first) and \\
\hline 2239 & & & the secondary key being filename in the collating sequence. \\
\hline 22396 & & -u & Use time of last access (see <sys/stat.h>) instead of last modification of the file for \\
\hline 2239 & & & \\
\hline 22398 & & -x & The same as -C, except that the multi-text-column output is produced with entries \\
\hline 223 & & & sorted across, rather than down, the columns. \\
\hline 22400 & & -1 & (The numeric digit one.) Force output to be one entry per line. \\
\hline 22401 & & & nore than one of the options in the following mutually-exclusive pairs shall not be \\
\hline 22402 & & con & \(n\) error: \(\mathbf{- C}\) and \(\mathbf{- 1}(\mathrm{ell}),-\mathbf{m}\) and \(-\mathbf{1}\) (ell), \(\mathbf{- x}\) and \(\mathbf{- 1}\) (ell), \(\mathbf{- C}\) and \(\mathbf{- 1}\) (one), \(\mathbf{- H}\) and \(-\mathbf{L}\), \\
\hline 22403 & & -c & \(t\) and \(-\mathbf{S}\). The last option specified in each pair shall determine the output format. \\
\hline
\end{tabular}

OPERANDS
The following operand shall be supported:
file A pathname of a file to be written. If the file specified is not found, a diagnostic message shall be output on standard error.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

None.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(l s\) :
COLUMNS Determine the user's preferred column position width for writing multiple textcolumn output. If this variable contains a string representing a decimal integer, the Is utility shall calculate how many pathname text columns to write (see -C) based on the width provided. If COLUMNS is not set or invalid, an implementationdefined number of column positions shall be assumed, based on the implementation's knowledge of the output device. The column width chosen to write the names of files in any given directory shall be constant. Filenames shall not be truncated to fit into the multiple text-column output.

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for character collation information in determining the pathname collation sequence.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and which characters are defined as printable (character class print).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME Determine the format and contents for date and time strings written by \(l s\).
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
\(T Z \quad\) Determine the timezone for date and time strings written by \(l s\). If \(T Z\) is unset or null, an unspecified default timezone shall be used.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The default format shall be to list one entry per line to standard output; the exceptions are to terminals or when one of the \(-\mathbf{C},-\mathbf{m}\), or \(-\mathbf{x}\) options is specified. If the output is to a terminal, the format is implementation-defined.
When \(-\mathbf{m}\) is specified, the format used shall be:
"\%s, \%s, ...\n", <filename1>, <filename2>
where the largest number of filenames shall be written without exceeding the length of the line.
If the -i option is specified, the file's file serial number (see <sys/stat.h>) shall be written in the following format before any other output for the corresponding entry:
```

%u ", <file serial number>

```

If the \(-\mathbf{l}\) option is specified without \(-\mathbf{L}\), the following information shall be written:
```

"%s %u %s %s %u %s %s\n", <file mode>, <number of links>,
<owner name>, <group name>, <number of bytes in the file>,
<date and time>, <pathname>

```

If the file is a symbolic link, this information shall be about the link itself and the <pathname> field shall be of the form:
"\%s -> \%s", <pathname of link>, <contents of link>
If both -1 and \(-\mathbf{L}\) are specified, the following information shall be written:
```

"%S %u %s %s %u %s %s\n", <file mode>, <number of links>,
<owner name>, <group name>, <number of bytes in the file>,
<date and time>, <pathname of link>

```
where all fields except <pathname of link> shall be for the file resolved from the symbolic link.
The \(-\mathbf{n},-\mathbf{g}\), and \(-\mathbf{o}\) options use the same format as \(-\mathbf{1}\), but with omitted items and their associated <blank>s. See the OPTIONS section.

In both the preceding \(\mathbf{- 1}\) forms, if <owner name> or <group name> cannot be determined, or if \(\mathbf{- n}\) is given, they shall be replaced with their associated numeric values using the format \%u.
The <date and time> field shall contain the appropriate date and timestamp of when the file was last modified. In the POSIX locale, the field shall be the equivalent of the output of the following date command:
date "+\%b \%e \% \(\mathrm{H}: \circ \mathrm{M} "\)
if the file has been modified in the last six months, or:
```

date "+%b %e %Y"

```
(where two <space>s are used between \%e and \%y) if the file has not been modified in the last six months or if the modification date is in the future, except that, in both cases, the final <newline> produced by date shall not be included and the output shall be as if the date command were executed at the time of the last modification date of the file rather than the current time. When the LC_TIME locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.
If the file is a character special or block special file, the size of the file may be replaced with implementation-defined information associated with the device in question.
If the pathname was specified as a file operand, it shall be written as specified.
xSI The file mode written under the \(-\mathbf{l}, \mathbf{-},-\mathbf{g}\), and \(-\mathbf{o}\) options shall consist of the following format:
```

"%c%s%s%s%s", <entry type>, <owner permissions>,
<group permissions>, <other permissions>,
<optional alternate access method flag>

```

The <optional alternate access method flag> shall be the empty string if there is no alternate or additional access control method associated with the file; otherwise, it shall be a string containing a single printable character that is not a <blank>.
The <entry type> character shall describe the type of file, as follows:
\begin{tabular}{lll}
22492 & d & Directory. \\
22493 & b & Block special file. \\
22494 & c & Character special file. \\
22495 & l (ell) & Symbolic link. \\
22496 & p & FIFO. \\
22497 & - & Regular file.
\end{tabular}

Implementations may add other characters to this list to represent other implementation-defined file types.
The next three fields shall be three characters each:
<owner permissions>
Permissions for the file owner class (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.4, File Access Permissions).
<group permissions>
Permissions for the file group class.
<other permissions>
Permissions for the file other class.
Each field shall have three character positions:
1. If ' \(r\) ', the file is readable; if ' - ', the file is not readable.
2. If ' \(w\) ' , the file is writable; if \({ }^{\prime}-\) ', the file is not writable.
3. The first of the following that applies:

S If in <owner permissions>, the file is not executable and set-user-ID mode is set. If in <group permissions>, the file is not executable and set-group-ID mode is set.
s If in <owner permissions>, the file is executable and set-user-ID mode is set. If in <group permissions>, the file is executable and set-group-ID mode is set.

XSI

XSI
22519

If this string is the first thing to be written, the first <newline> shall not be written. This output shall precede the number of units in the directory.
xSI If the -s option is given, each file shall be written with the number of blocks used by the file. Along with \(-\mathbf{C}, \mathbf{- 1}, \mathbf{- m}\), or \(-\mathbf{x}\), the number and a <space> shall precede the filename; with \(-\mathbf{g},-\mathbf{l}\), \(-\mathbf{n}\), or \(-\mathbf{o}\), they shall precede each line describing a file.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

None.

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

\section*{Default.}

\section*{APPLICATION USAGE}

Many implementations use the equal sign \(\left({ }^{\prime}=^{\prime}\right)\) to denote sockets bound to the file system for the \(-\mathbf{F}\) option. Similarly, many historical implementations use the ' s ' character to denote sockets as the entry type characters for the -1 option.
It is difficult for an application to use every part of the file modes field of \(l s-1\) in a portable manner. Certain file types and executable bits are not guaranteed to be exactly as shown, as implementations may have extensions. Applications can use this field to pass directly to a user printout or prompt, but actions based on its contents should generally be deferred, instead, to the test utility.

The output of \(l s\) (with the -1 and related options) contains information that logically could be used by utilities such as chmod and touch to restore files to a known state. However, this information is presented in a format that cannot be used directly by those utilities or be easily translated into a format that can be used. A character has been added to the end of the permissions string so that applications at least have an indication that they may be working in an area they do not understand instead of assuming that they can translate the permissions string into something that can be used. Future issues or related documents may define one or more specific characters to be used based on different standard additional or alternative access control mechanisms.

As with many of the utilities that deal with filenames, the output of \(l s\) for multiple files or in one of the long listing formats must be used carefully on systems where filenames can contain embedded white space. Systems and system administrators should institute policies and user training to limit the use of such filenames.

The number of disk blocks occupied by the file that it reports varies depending on underlying file system type, block size units reported, and the method of calculating the number of blocks. On some file system types, the number is the actual number of blocks occupied by the file (counting indirect blocks and ignoring holes in the file); on others it is calculated based on the file size (usually making an allowance for indirect blocks, but ignoring holes).

\section*{EXAMPLES}

An example of a small directory tree being fully listed with \(l s-l a R F ~ a ~ i n ~ t h e ~ P O S I X ~ l o c a l e: ~\)

\section*{RATIONALE}

Some historical implementations of the \(l s\) utility show all entries in a directory except dot and dot-dot when a superuser invokes \(l s\) without specifying the -a option. When "normal" users invoke \(l s\) without specifying -a, they should not see information about any files with names beginning with a period unless they were named as file operands.

Implementations are expected to traverse arbitrary depths when processing the \(-\mathbf{R}\) option. The only limitation on depth should be based on running out of physical storage for keeping track of untraversed directories.

The \(\mathbf{- 1}\) (one) option was historically found in BSD and BSD-derived implementations only. It is required in this volume of IEEE Std 1003.1-200x so that conforming applications might ensure that output is one entry per line, even if the output is to a terminal.
The -S option was added in Issue 7, but had been provided by several implementations for many years. The description given in the standard documents historic practice, but does not match much of the documentation that described its behavior. Historical documentation typically described it as something like:
-S Sort by size (largest size first) instead of by name. Special character devices (listed last) are sorted by name.
even though the file type was never considered when sorting the output. Character special files do typically sort close to the end of the list because their file size on most implementations is zero. But they are sorted alphabetically with any other files that happen to have the same file size (zero), not sorted separately and added to the end.
Generally, this volume of IEEE Std 1003.1-200x is silent about what happens when options are given multiple times. In the cases of \(-\mathbf{C}, \mathbf{- 1}\), and \(\mathbf{- 1}\), however, it does specify the results of these overlapping options. Since \(l_{s}\) is one of the most aliased commands, it is important that the implementation perform intuitively. For example, if the alias were:
```

alias ls="ls -C"

```
and the user typed \(l s \mathbf{- 1}\), single-text-column output should result, not an error.
Earlier versions of this standard did not describe the BSD -A option (like -a, but dot and dot-dot are not written out). It has been added due to widespread implementation.
Implementations may make \(-\mathbf{q}\) the default for terminals to prevent trojan horse attacks on terminals with special escape sequences. This is not required because:
- Some control characters may be useful on some terminals; for example, a system might write them as " \(\backslash 001\) " or " "A".
- Special behavior for terminals is not relevant to applications portability.

An early proposal specified that the <optional alternate access method flag> had to be ' + ' if there was an alternate access method used on the file or <space> if there was not. This was changed to be <space> if there is not and a single printable character if there is. This was done for three reasons:
1. There are historical implementations using characters other than ' + '.
2. There are implementations that vary this character used in that position to distinguish between various alternate access methods in use.
3. The standard developers did not want to preclude future specifications that might need a way to specify more than one alternate access method.
Nonetheless, implementations providing a single alternate access method are encouraged to use ' \({ }^{\prime}\) '.

In an early proposal, the units used to specify the number of blocks occupied by files in a directory in an \(l s-1\) listing were implementation-defined. This was because BSD systems have historically used 1024 -byte units and System V systems have historically used 512-byte units. It was pointed out by BSD developers that their system has used 512-byte units in some places and 1024 -byte units in other places. (System \(V\) has consistently used 512.) Therefore, this volume of IEEE Std 1003.1-200x usually specifies 512. Future releases of BSD are expected to consistently provide 512 bytes as a default with a way of specifying 1024-byte units where appropriate.

The <date and time> field in the -1 format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of IEEE Std 1003.1-200x, as the appropriate vehicle is a messaging system; that is, the format should be specified as a "message".

\section*{FUTURE DIRECTIONS}

The -s uses implementation-defined units and cannot be used portably; it may be withdrawn in a future version.

\section*{SEE ALSO}
chmod, find, the System Interfaces volume of IEEE Std 1003.1-200x, stat(), the Base Definitions volume of IEEE Std 1003.1-200x, <sys/stat.h>

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{Issue 5}

A second FUTURE DIRECTION is added.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- In the -F option, other symbols are allowed for other file types.

Treatment of symbolic links is added, as defined in the IEEE P1003.2b draft standard.
The Open Group Base Resolution bwg2001-010 is applied, adding the T and t fields as part of the XSI option.

\section*{Issue 7}

SD5-XCU-ERN-50 is applied, adding the -A option.
Austin Group Interpretation 1003.1-2001 \#101 is applied, clarifying the optional alternate access method flag in the STDOUT section.
The -S option is added from The Open Group Technical Standard, 2006, Extended API Set

\section*{Part 1.}

The \(-\mathbf{m},-\mathbf{n},-\mathbf{p}\), and \(-\mathbf{x}\) options are moved from the XSI option to the Base.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
m4 - macro processor

\section*{SYNOPSIS}

\section*{DESCRIPTION}

The \(m 4\) utility is a macro processor that shall read one or more text files, process them according to their included macro statements, and write the results to standard output.

\section*{OPTIONS}

The \(m 4\) utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of the -D and -U options shall be significant, and options can be interspersed with operands.
The following options shall be supported:
-s Enable line synchronization output for the c99 preprocessor phase (that is, \#line directives).
-D name[=val]
Define name to val or to null if =val is omitted.
-U name Undefine name.

\section*{OPERANDS}

The following operand shall be supported:
file A pathname of a text file to be processed. If no file is given, or if it is ' \(\prime^{\prime}\), the standard input shall be read.

\section*{STDIN}

The standard input shall be a text file that is used if no file operand is given, or if it is ' - '.

\section*{INPUT FILES}

The input file named by the file operand shall be a text file.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of \(m 4\) :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{ASYNCHRONOUS EVENTS}

Default.

\section*{STDOUT}

The standard output shall be the same as the input files, after being processed for macro expansion.

\section*{STDERR}

The standard error shall be used to display strings with the errprint macro, macro tracing enabled by the traceon macro, the defined text for macros written by the dumpdef macro, or for diagnostic messages.

\section*{OUTPUT FILES}

None.

\section*{EXTENDED DESCRIPTION}

The \(m 4\) utility shall compare each token from the input against the set of built-in and userdefined macros. If the token matches the name of a macro, then the token shall be replaced by the macro's defining text, if any, and rescanned for matching macro names. Once no portion of the token matches the name of a macro, it shall be written to standard output. Macros may have arguments, in which case the arguments shall be substituted into the defining text before it is rescanned.

Macro calls have the form:
name(arg1, arg2, ..., argn)
Macro names shall consist of letters, digits, and underscores, where the first character is not a digit. Tokens not of this form shall not be treated as macros.
The application shall ensure that the left parenthesis immediately follows the name of the macro. If a token matching the name of a macro is not followed by a left parenthesis, it is handled as a use of that macro without arguments.
If a macro name is followed by a left parenthesis, its arguments are the comma-separated tokens between the left parenthesis and the matching right parenthesis. Unquoted <blank>s and <newline>s preceding each argument shall be ignored. All other characters, including trailing <blank>s and <newline>s, are retained. Commas enclosed between left and right parenthesis characters do not delimit arguments.
Arguments are positionally defined and referenced. The string "\$1" in the defining text shall be replaced by the first argument. Systems shall support at least nine arguments; only the first nine can be referenced, using the strings "\$1" to "\$9", inclusive. The string "\$0" is replaced with the name of the macro. The string "\$\#" is replaced by the number of arguments as a string. The string "\$*" is replaced by a list of all of the arguments, separated by commas. The string "\$@" is replaced by a list of all of the arguments separated by commas, and each argument is quoted using the current left and right quoting strings. The string "\$ \{ " produces unspecified behavior.
If fewer arguments are supplied than are in the macro definition, the omitted arguments are taken to be null. It is not an error if more arguments are supplied than are in the macro definition.

No special meaning is given to any characters enclosed between matching left and right quoting strings, but the quoting strings are themselves discarded. By default, the left quoting string consists of a grave accent ( \({ }^{\prime}{ }^{\prime}\) ) and the right quoting string consists of an acute accent ( \({ }^{\prime}{ }^{\prime}\) ); ;ee also the changequote macro.
Comments are written but not scanned for matching macro names; by default, the begincomment string consists of the number sign character and the end-comment string consists of a <newline>. See also the changecom and dnl macros.

The \(m 4\) utility shall make available the following built-in macros. They can be redefined, but once this is done the original meaning is lost. Their values shall be null unless otherwise stated. In the descriptions below, the term defining text refers to the value of the macro: the second argument to the define macro, among other things. Except for the first argument to the eval macro, all numeric arguments to built-in macros shall be interpreted as decimal values. The string values produced as the defining text of the decr, divnum, incr, index, len, and sysval built-in macros shall be in the form of a decimal-constant as defined in the C language.
changecom The changecom macro shall set the begin-comment and end-comment strings. With no arguments, the comment mechanism shall be disabled. With a single argument, that argument shall become the begin-comment string and the <newline> shall become the end-comment string. With two arguments, the first argument shall become the begin-comment string and the second argument shall become the end-comment string. Systems shall support comment strings of at least five characters.
changequote The changequote macro shall set the begin-quote and end-quote strings. With no arguments, the quote strings shall be set to the default values (that is, ' '). The behavior is unspecified if there is a single argument or either argument is null. With two non-null arguments, the first argument shall become the begin-quote string and the second argument shall become the end-quote string. Systems shall support quote strings of at least five characters.
decr The defining text of the decr macro shall be its first argument decremented by 1. It shall be an error to specify an argument containing any non-numeric characters.
define \(\quad\) The second argument shall become the defining text of the macro whose name is the first argument. It is unspecified whether the define macro deletes all prior definitions of the macro named by its first argument or preserves all but the current definition of the macro.
defn \(\quad\) The defining text of the defn macro shall be the quoted definition (using the current quoting strings) of its arguments.
divert The \(m 4\) utility maintains nine temporary buffers, numbered 1 to 9 , inclusive. When the last of the input has been processed, any output that has been placed in these buffers shall be written to standard output in buffer-numerical order. The divert macro shall divert future output to the buffer specified by its argument. Specifying no argument or an argument of 0 shall resume the normal output process. Output diverted to a stream with a negative number shall be discarded. Behavior is implementation-defined if a stream number larger than 9 is specified. It shall be an error to specify an argument containing any non-numeric characters.
divnum The defining text of the divnum macro shall be the number of the current output stream as a string.
dnl The dnl macro shall cause \(m 4\) to discard all input characters up to and including the next <newline>.
dumpdef The dumpdef macro shall write the defined text to standard error for each of the macros specified as arguments, or, if no arguments are specified, for all macros.
errprint The errprint macro shall write its arguments to standard error.
eval The eval macro shall evaluate its first argument as an arithmetic expression, using 32-bit signed integer arithmetic. All of the C-language operators shall be supported, except for:
[]
->
\begin{tabular}{ll}
22806 & ++ \\
22807 & -- \\
22808 & (type) \\
22809 & unary * \\
22810 & sizeof \\
22811 &, \\
22812 & - \\
22813 & ?: \\
22814 & unary \&
\end{tabular}

and all assignment operators. It shall be an error to specify any of these operators. Precedence and associativity shall be as in the ISO C standard. Systems shall support octal and hexadecimal numbers as in the ISO C standard. The second argument, if specified, shall set the radix for the result; the default is 10 . The third argument, if specified, sets the minimum number of digits in the result. It shall be an error to specify the second or third argument containing any non-numeric characters.
ifdef If the first argument to the ifdef macro is defined, the defining text shall be the second argument. Otherwise, the defining text shall be the third argument, if specified, or the null string, if not.
ifelse The ifelse macro takes three or more arguments. If the first two arguments compare as equal strings (after macro expansion of both arguments), the defining text shall be the third argument. If the first two arguments do not compare as equal strings and there are three arguments, the defining text shall be null. If the first two arguments do not compare as equal strings and there are four or five arguments, the defining text shall be the fourth argument. If the first two arguments do not compare as equal strings and there are six or more arguments, the first three arguments shall be discarded and processing shall restart with the remaining arguments.
include The defining text for the include macro shall be the contents of the file named by the first argument. It shall be an error if the file cannot be read.
The defining text of the incr macro shall be its first argument incremented by 1 . It shall be an error to specify an argument containing any non-numeric characters.
The defining text of the index macro shall be the first character position (as a string) in the first argument where a string matching the second argument begins (zero origin), or -1 if the second argument does not occur.
len \(\quad\) The defining text of the len macro shall be the length (as a string) of the first argument.
m4exit Exit from the \(m 4\) utility. If the first argument is specified, it is the exit code. The default is zero. It shall be an error to specify an argument containing any nonnumeric characters.
m4wrap The first argument shall be processed when EOF is reached. If the m4wrap macro is used multiple times, the arguments specified shall be processed in the order in which the m4wrap macros were processed.
maketemp The defining text shall be the first argument, with any trailing ' x ' characters replaced with the current process ID as a string.
popdef The popdef macro shall delete the current definition of its arguments, replacing that definition with the previous one. If there is no previous definition, the macro is undefined.
\begin{tabular}{|c|c|c|}
\hline 22855 & pushdef & The pushdef macro shall be equivalent to the define macro with the exception that it shall preserve any current definition for future retrieval using the popdef macro. \\
\hline 22856
22857 & shift & The defining text for the shift macro shall be all of its arguments except for the first one. \\
\hline 22858
22859 & sinclude & The sinclude macro shall be equivalent to the include macro, except that it shall not be an error if the file is inaccessible. \\
\hline \[
\begin{aligned}
& 22860 \\
& 22861 \\
& 22862 \\
& 22863 \\
& 22864 \\
& 22865 \\
& 22866
\end{aligned}
\] & substr & The defining text for the substr macro shall be the substring of the first argument beginning at the zero-offset character position specified by the second argument. The third argument, if specified, shall be the number of characters to select; if not specified, the characters from the starting point to the end of the first argument shall become the defining text. It shall not be an error to specify a starting point beyond the end of the first argument and the defining text shall be null. It shall be an error to specify an argument containing any non-numeric characters. \\
\hline 22867
22868
22869
22870
22871 & syscmd & The syscmd macro shall interpret its first argument as a shell command line. The defining text shall be the string result of that command. The string result shall not be rescanned for macros while setting the defining text. No output redirection shall be performed by the \(m 4\) utility. The exit status value from the command can be retrieved using the sysval macro. \\
\hline 22872
2283 & sysval & The defining text of the sysval macro shall be the exit value of the utility last invoked by the syscmd macro (as a string). \\
\hline 22874
22875
22876 & traceon & The traceon macro shall enable tracing for the macros specified as arguments, or, if no arguments are specified, for all macros. The trace output shall be written to standard error in an unspecified format. \\
\hline 22877
22878 & traceoff & The traceoff macro shall disable tracing for the macros specified as arguments, or, if no arguments are specified, for all macros. \\
\hline \begin{tabular}{l}
22879 \\
22880 \\
22881 \\
22882 \\
22883
\end{tabular} & translit & The defining text of the translit macro shall be the first argument with every character that occurs in the second argument replaced with the corresponding character from the third argument. The behavior is unspecified if the ' - ' character appears within the second or third argument anywhere besides the first or last character. \\
\hline 22884
22885 & undefine & The undefine macro shall delete all definitions (including those preserved using the pushdef macro) of the macros named by its arguments. \\
\hline \[
\begin{aligned}
& 22886 \\
& 22887 \\
& 22888 \\
& 22889 \\
& 22890
\end{aligned}
\] & undivert & The undivert macro shall cause immediate output of any text in temporary buffers named as arguments, or all temporary buffers if no arguments are specified. Buffers can be undiverted into other temporary buffers. Undiverting shall discard the contents of the temporary buffer. The behavior is unspecified if an argument contains any non-numeric characters. \\
\hline
\end{tabular}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred
If the m4exit macro is used, the exit value can be specified by the input file.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

The defn macro is useful for renaming macros, especially built-ins.
When a macro has been multiply defined via the pushdef macro, it is unspecified whether the define macro will alter only the most recent definition (as though by popdef and pushdef), or replace the entire stack of definitions with a single definition (as though by undefine and pushdef). An application desiring particular behavior for the define macro in this case can redefine it accordingly.

\section*{EXAMPLES}

If the file \(\mathbf{m 4 s r c}\) contains the lines:
```

The value of 'VER' is "VER".
ifdef('VER', ''VER'' is defined to be VER., VER is not defined.)
ifelse(VER, 1, ''VER'' is 'VER'.)
ifelse(VER, 2, '`VER'' is 'VER'., '`VER'' is not 2.)
end

```
then the command
```

m4 m4src

```
or the command:
m4 -U VER m4src
produces the output:
The value of VER is "VER".
VER is not defined.
VER is not 2.
end

The command:
```

m4 -D VER m4src

```
produces the output:
```

The value of VER is "".
VER is defined to be.
VER is not 2.
end

```

The command:
```

m4 -D VER=1 m4src

```
produces the output:
The value of VER is "1".
VER is defined to be 1.
VER is 1.
VER is not 2.
end

The command:
```

m4 -D VER=2 m4src
produces the output:
The value of VER is "2".
VER is defined to be 2.

```
```

VER is 2.
end

```

\section*{RATIONALE}

Historic System V-based behavior treated "\$ \{" in a macro definition as two literal characters. However, this sequence is left unspecified so that implementations may offer extensions such as "\$\{11\}" meaning the eleventh positional parameter. Macros can still be defined with appropriate uses of nested quoting to result in a literal "\$ \(\{\) " in the output after rescanning removes the nested quotes.

Historic System V-based behavior treated ' -' as a literal; GNU behavior treats it as a range. This version of the standard allows either behavior.

\section*{FUTURE DIRECTIONS}

None.

\section*{SEE ALSO}
c99

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{Issue 5}

The phrase "the defined text for macros written by the dumpdef macro" is added to the description of STDERR, and the description of dumpdef is updated to indicate that output is written to standard error. The description of eval is updated to indicate that the list of excluded C operators excludes unary ' \(\varepsilon^{\prime}\) and '. '. In the description of ifdef, the phrase "and it is not defined to be zero' is deleted.

Issue 6
In the EXTENDED DESCRIPTION, the eval text is updated to include \(a^{\prime} \varepsilon^{\prime}\) character in the excepted list.
The EXTENDED DESCRIPTION of divert is updated to clarify that there are only nine diversion buffers.

The normative text is reworded to avoid use of the term "must" for application requirements.
The Open Group Base Resolution bwg2000-006 is applied.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/31 is applied, replacing the EXAMPLES section.

\section*{Issue 7}

The \(m 4\) utility is moved from the XSI option to the Base.
SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply (options can be interspersed with operands).
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-99 is applied, clarifying the definition of the divert macro in the EXTENDED DESCRIPTION.

SD5-XCU-ERN-100 is applied, clarifying the definition of the syscmd macro in the EXTENDED DESCRIPTION.

SD5-XCU-ERN-101 is applied, clarifying the definition of the undivert macro in the EXTENDED DESCRIPTION.

SD5-XCU-ERN-111 is applied to the EXTENDED DESCRIPTION, clarifying that the string "\$ \(\{\) " produces unspecified behavior.
SD5-XCU-ERN-112 is applied, updating the changequote macro.

SD5-XCU-ERN-118 is applied, clarifying the definition of the define and translit macros in the EXTENDED DESCRIPTION.

```

\section*{DESCRIPTION}

The mailx utility provides a message sending and receiving facility. It has two major modes, selected by the options used: Send Mode and Receive Mode.
On systems that do not support the User Portability Utilities option, an application using mailx shall have the ability to send messages in an unspecified manner (Send Mode). Unless the first character of one or more lines is tilde ( \(\prime^{\sim \prime}\) ), all characters in the input message shall appear in the delivered message, but additional characters may be inserted in the message before it is retrieved.
up On systems supporting the User Portability Utilities option, mail-receiving capabilities and other interactive features, Receive Mode, described below, also shall be enabled.

\section*{Send Mode}

Send Mode can be used by applications or users to send messages from the text in standard input.

\section*{UP \\ Receive Mode}

Receive Mode is more oriented towards interactive users. Mail can be read and sent in this interactive mode.
When reading mail, mailx provides commands to facilitate saving, deleting, and responding to messages. When sending mail, mailx allows editing, reviewing, and other modification of the message as it is entered.
Incoming mail shall be stored in one or more unspecified locations for each user, collectively called the system mailbox for that user. When mailx is invoked in Receive Mode, the system mailbox shall be the default place to find new mail. As messages are read, they shall be marked to be moved to a secondary file for storage, unless specific action is taken. This secondary file is called the mbox and is normally located in the directory referred to by the HOME environment variable (see MBOX in the ENVIRONMENT VARIABLES section for a description of this file). Messages shall remain in this file until explicitly removed. When the -f option is used to read mail messages from secondary files, messages shall be retained in those files unless specifically removed. All three of these locations-system mailbox, mbox, and secondary file-are referred to in this section as simply "mailboxes", unless more specific identification is required.

\section*{OPTIONS}

The mailx utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported. (Only the -s subject option shall be required on all systems. The other options are required only on systems supporting the User Portability Utilities option.) nothing and exit with a successful return code if there is mail to read. Read messages from the file named by the file operand instead of the system mailbox. (See also folder.) If no file operand is specified, read messages from mbox instead of the system mailbox.
UP \(\quad \mathbf{F} \quad\) Record the message in a file named after the first recipient. The name is the loginname portion of the address found first on the To: line in the mail header. Overrides the record variable, if set (see Internal Variables in mailx (on page 595).)
up \(\quad-\mathbf{H} \quad\) Write a header summary only.
UP \(\quad-\mathbf{i} \quad\) Ignore interrupts. (See also ignore.)
UP -n Do not initialize from the system default start-up file. See the EXTENDED DESCRIPTION section.
-N Do not write an initial header summary.
-s subject Set the Subject header field to subject. All characters in the subject string shall appear in the delivered message. The results are unspecified if subject is longer than \{LINE_MAX -10 bytes or contains a <newline>.
UP -u user Read the system mailbox of the login name user. This shall only be successful if the invoking user has the appropriate privileges to read the system mailbox of that user.

\section*{OPERANDS}

The following operands shall be supported:
address Addressee of message. When \(-\mathbf{n}\) is specified and no user start-up files are accessed (see the EXTENDED DESCRIPTION section), the user or application shall ensure this is an address to pass to the mail delivery system. Any system or user start-up files may enable aliases (see alias under Commands in mailx (on page 598)) that may modify the form of address before it is passed to the mail delivery system.
UP file A pathname of a file to be read instead of the system mailbox when \(-\mathbf{f}\) is specified. The meaning of the file option-argument shall be affected by the contents of the folder internal variable; see Internal Variables in mailx (on page 595).

\section*{STDIN}

When mailx is invoked in Send Mode (the first synopsis line), standard input shall be the
up message to be delivered to the specified addresses. When in Receive Mode, user commands shall be accepted from stdin. If the User Portability Utilities option is not supported, standard input lines beginning with a tilde ( \({ }^{\prime} \sim \prime\) ) character produce unspecified results.
up If the User Portability Utilities option is supported, then in both Send and Receive Modes, standard input lines beginning with the escape character (usually tilde ( \({ }^{\prime} \sim \prime\) ) ) shall affect processing as described in Command Escapes in mailx (on page 606).

\section*{INPUT FILES}

When mailx is used as described by this volume of IEEE Std 1003.1-200x, the file optionargument (see the -f option) and the mbox shall be text files containing mail messages, formatted as described in the OUTPUT FILES section. The nature of the system mailbox is unspecified; it need not be a file.

\section*{ENVIRONMENT VARIABLES}

UP Some of the functionality described in this section shall be provided on implementations that support the User Portability Utilities option as described in the text, and is not further shaded for this option.
The following environment variables shall affect the execution of mailx:
\(D E A D \quad\) Determine the pathname of the file in which to save partial messages in case of interrupts or delivery errors. The default shall be dead.letter in the directory named by the HOME variable. The behavior of mailx in saving partial messages is unspecified if the User Portability Utilities option is not supported and DEAD is not defined with the value \(/ \mathbf{d e v} / \mathbf{n u l l}\).
EDITOR Determine the name of a utility to invoke when the edit (see Commands in mailx (on page 598)) or \({ }^{\text {n (see Command Escapes in mailx (on page 606)) command is }}\)
xsi used. The default editor is unspecified. On XSI-conformant systems it is ed. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
HOME Determine the pathname of the user's home directory.
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the handling of case-insensitive address and header-field comparisons.
LC_TIME This variable may determine the format and contents of the date and time strings written by mailx. This volume of IEEE Std 1003.1-200x specifies the effects of this variable only for systems supporting the User Portability Utilities option.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
LISTER Determine a string representing the command for writing the contents of the folder directory to standard output when the folders command is given (see folders in Commands in mailx (on page 598)). Any string acceptable as a command_string operand to the sh -c command shall be valid. If this variable is null or not set, the output command shall be \(l\) s. The effects of this variable are unspecified if the User Portability Utilities option is not supported.
MAILRC Determine the pathname of the start-up file. The default shall be .mailrc in the directory referred to by the HOME environment variable. The behavior of mailx is unspecified if the User Portability Utilities option is not supported and MAILRC is not defined with the value \(/ \mathbf{d e v} / \mathbf{n u l l}\).
\begin{tabular}{lll}
23117 & MBOX & \begin{tabular}{l} 
Determine a pathname of the file to save messages from the system mailbox that \\
have been read. The exit command shall override this function, as shall saving the
\end{tabular} \\
23118 \\
2319 \\
23120 \\
23121 & message explicitly in another file. The default shall be mbox in the directory \\
named by the HOME variable. The effects of this variable are unspecified if the \\
User Portability Utilities option is not supported.
\end{tabular}

\section*{ASYNCHRONOUS EVENTS}

When mailx is in Send Mode and standard input is not a terminal, it shall take the standard action for all signals.
UP In Receive Mode, or in Send Mode when standard input is a terminal, if a SIGINT signal is received:

UP
-command-mode prompt shall be written.
2. If in input mode:
a. If ignore is set, mailx shall write "@ \(\backslash n\) ", discard the current input line, and continue processing, bypassing the message-abort mechanism described in item \(2 b\).
b. If the interrupt was received while sending mail, either when in Receive Mode or in Send Mode, a message shall be written, and another subsequent interrupt, with no other intervening characters typed, shall be required to abort the mail message. If in Receive Mode and another interrupt is received, a command-mode prompt shall be written. If in Send Mode and another interrupt is received, mailx shall terminate with a non-zero status.

In both cases listed in item \(b\), if the message is not empty:

UP

UP
UP
i. If save is enabled and the file named by \(D E A D\) can be created, the message shall be written to the file named by \(D E A D\). If the file exists, the message shall be written to replace the contents of the file.
ii. If save is not enabled, or the file named by \(D E A D\) cannot be created, the message shall not be saved.

The mailx utility shall take the standard action for all other signals.

\section*{STDOUT}

In command and input modes, all output, including prompts and messages, shall be written to standard output.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

Various mailx commands and command escapes can create or add to files, including the mbox, the dead-letter file, and secondary mailboxes. When mailx is used as described in this volume of IEEE Std 1003.1-200x, these files shall be text files, formatted as follows:
```

line beginning with From<space>
[one or more header-lines; see Commands in mailx (on page 598)]
empty line
[zero or more body lines
empty line]
[line beginning with From<space>...]

```
where each message begins with the From <space> line shown, preceded by the beginning of the file or an empty line. (The From <space> line is considered to be part of the message header, but not one of the header-lines referred to in Commands in mailx (on page 598); thus, it shall not be affected by the discard, ignore, or retain commands.) The formats of the remainder of the From <space> line and any additional header lines are unspecified, except that none shall be empty. The format of a message body line is also unspecified, except that no line following an empty line shall start with From <space>; mailx shall modify any such user-entered message body lines (following an empty line and beginning with From <space>) by adding one or more characters to precede the ' \(F^{\prime}\); it may add these characters to From <space> lines that are not preceded by an empty line.
When a message from the system mailbox or entered by the user is not a text file, it is implementation-defined how such a message is stored in files written by mailx.

\section*{EXTENDED DESCRIPTION}

UP The functionality in the entire EXTENDED DESCRIPTION section shall be provided on implementations supporting the User Portability Utilities option. The functionality described in this section shall be provided on implementations that support the User Portability Utilities option (and the rest of this section is not further shaded for this option).
The mailx utility need not support for all character encodings in all circumstances. For example, inter-system mail may be restricted to 7-bit data by the underlying network, 8-bit data need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used.
When mailx is invoked using one of the Receive Mode synopsis forms, it shall write a page of header-summary lines (if \(-\mathbf{N}\) was not specified and there are messages, see below), followed by a prompt indicating that mailx can accept regular commands (see Commands in mailx (on page 598)); this is termed command mode. The page of header-summary lines shall contain the first
new message if there are new messages, or the first unread message if there are unread messages, or the first message. When mailx is invoked using the Send Mode synopsis and standard input is a terminal, if no subject is specified on the command line and the asksub variable is set, a prompt for the subject shall be written. At this point, mailx shall be in input mode. This input mode shall also be entered when using one of the Receive Mode synopsis forms and a reply or new message is composed using the reply, Reply, followup, Followup, or mail commands and standard input is a terminal. When the message is typed and the end of the message is encountered, the message shall be passed to the mail delivery software. Commands can be entered by beginning a line with the escape character (by default, tilde ( \({ }^{\prime} \sim \prime\) ) ) followed by a single command letter and optional arguments. See Commands in mailx for a summary of these commands. It is unspecified what effect these commands will have if standard input is not a terminal when a message is entered using either the Send Mode synopsis, or the Read Mode commands reply, Reply, followup, Followup, or mail.
Note: For notational convenience, this section uses the default escape character, tilde, in all references and examples.

At any time, the behavior of mailx shall be governed by a set of environmental and internal variables. These are flags and valued parameters that can be set and cleared via the mailx set and unset commands.

Regular commands are of the form:
[command] [msglist] [argument ...]
If no command is specified in command mode, next shall be assumed. In input mode, commands shall be recognized by the escape character, and lines not treated as commands shall be taken as input for the message.
In command mode, each message shall be assigned a sequential number, starting with 1.
All messages have a state that shall affect how they are displayed in the header summary and how they are retained or deleted upon termination of mailx. There is at any time the notion of a current message, which shall be marked by a '>' at the beginning of a line in the header summary. When mailx is invoked using one of the Receive Mode synopsis forms, the current message shall be the first new message, if there is a new message, or the first unread message if there is an unread message, or the first message if there are any messages, or unspecified if there are no messages in the mailbox. Each command that takes an optional list of messages (msglist) or an optional single message (message) on which to operate shall leave the current message set to the highest-numbered message of the messages specified, unless the command deletes messages, in which case the current message shall be set to the first undeleted message (that is, a message not in the deleted state) after the highest-numbered message deleted by the command, if one exists, or the first undeleted message before the highest-numbered message deleted by the command, if one exists, or to an unspecified value if there are no remaining undeleted messages. All messages shall be in one of the following states:
new \(\quad\) The message is present in the system mailbox and has not been viewed by the user or moved to any other state. Messages in state new when mailx quits shall be retained in the system mailbox.
unread The message has been present in the system mailbox for more than one invocation of mailx and has not been viewed by the user or moved to any other state. Messages in state unread when mailx quits shall be retained in the system mailbox.
read The message has been processed by one of the following commands: \(\sim \mathfrak{f},{ }^{\sim} \mathbf{m},{ }^{\sim} \mathbf{F},{ }^{\sim} \mathbf{M}\), copy, mbox, next, pipe, print, Print, top, type, Type, undelete. The delete, dp, and dt commands may also cause the next message to be marked as read, depending on the value of the autoprint variable. Messages that are in the system mailbox and in state read when mailx quits shall be saved in the mbox, unless the internal variable hold was set. Messages that are in the mbox or in a secondary
mailbox and in state read when mailx quits shall be retained in their current location.
deleted The message has been processed by one of the following commands: delete, \(\mathbf{d p}, \mathbf{d t}\). Messages in state deleted when mailx quits shall be deleted. Deleted messages shall be ignored until mailx quits or changes mailboxes or they are specified to the undelete command; for example, the message specification /string shall only search the subject lines of messages that have not yet been deleted, unless the command operating on the list of messages is undelete. No deleted message or deleted message header shall be displayed by any mailx command other than undelete.
preserved The message has been processed by a preserve command. When mailx quits, the message shall be retained in its current location.
saved The message has been processed by one of the following commands: save or write. If the current mailbox is the system mailbox, and the internal variable keepsave is set, messages in the state saved shall be saved to the file designated by the \(M B O X\) variable (see the ENVIRONMENT VARIABLES section). If the current mailbox is the system mailbox, messages in the state saved shall be deleted from the current mailbox, when the quit or file command is used to exit the current mailbox.

The header-summary line for each message shall indicate the state of the message.
Many commands take an optional list of messages (msglist) on which to operate, which defaults to the current message. A msglist is a list of message specifications separated by <blank>s, which can include:
\(\mathrm{n} \quad\) Message number \(n\).
\(+\quad\) The next undeleted message, or the next deleted message for the undelete command.
- The next previous undeleted message, or the next previous deleted message for the undelete command.
- The current message.
- The first undeleted message, or the first deleted message for the undelete command.
\$ The last message.
* Allmessages.
\(n-m \quad\) An inclusive range of message numbers.
address All messages from address; any address as shown in a header summary shall be matchable in this form.
/string All messages with string in the subject line (case ignored).
:c All messages of type \(c\), where \(c\) shall be one of:
d Deleted messages.
n New messages.
- Old messages (any not in state read or new).
r Read messages.
u Unread messages.
Other commands take an optional message (message) on which to operate, which defaults to the current message. All of the forms allowed for msglist are also allowed for message, but if more than one message is specified, only the first shall be operated on.

Other arguments are usually arbitrary strings whose usage depends on the command involved.

\section*{Start-Up in mailx}

At start-up time, mailx shall take the following steps in sequence:
1. Establish all variables at their stated default values.
2. Process command line options, overriding corresponding default values.
3. Import any of the DEAD, EDITOR, MBOX, LISTER, PAGER, SHELL, or VISUAL variables that are present in the environment, overriding the corresponding default values.
4. Read mailx commands from an unspecified system start-up file, unless the \(\mathbf{- n}\) option is given, to initialize any internal mailx variables and aliases.
5. Process the start-up file of mailx commands named in the user MAILRC variable.

Most regular mailx commands are valid inside start-up files, the most common use being to set up initial display options and alias lists. The following commands shall be invalid in the start-up file: !, edit, hold, mail, preserve, reply, Reply, shell, visual, Copy, followup, and Followup. Any errors in the start-up file shall either cause mailx to terminate with a diagnostic message and a non-zero status or to continue after writing a diagnostic message, ignoring the remainder of the lines in the start-up file.
A blank line in a start-up file shall be ignored.

\section*{Internal Variables in mailx}

The following variables are internal mailx variables. Each internal variable can be set via the mailx set command at any time. The unset and set no name commands can be used to erase variables.
In the following list, variables shown as:
variable
represent Boolean values. Variables shown as:
variable=value
shall be assigned string or numeric values. For string values, the rules in Commands in mailx concerning filenames and quoting shall also apply.
The defaults specified here may be changed by the unspecified system start-up file unless the user specifies the \(-\boldsymbol{n}\) option.
allnet All network names whose login name components match shall be treated as identical. This shall cause the msglist message specifications to behave similarly. The default shall be noallnet. See also the alternates command and the metoo variable.
append Append messages to the end of the mbox file upon termination instead of placing them at the beginning. The default shall be noappend. This variable shall not affect the save command when saving to mbox.
ask, asksub Prompt for a subject line on outgoing mail if one is not specified on the command line with the -s option. The ask and asksub forms are synonyms; the system shall refer to asksub and noasksub in its messages, but shall accept ask and noask as user input to mean asksub and noasksub. It shall not be possible to set both ask and noasksub, or noask and asksub. The default shall be asksub, but no prompting shall be done if standard input is not a terminal.

```

| keep | When a system mailbox, secondary mailbox, or mbox is empty, truncate it to zero <br> length instead of removing it. The default shall be nokeep. |
| :--- | :--- |
| keepsave | Keep the messages that have been saved from the system mailbox into other files <br> in the file designated by the variable $M B O X$, instead of deleting them. The default <br> shall be nokeepsave. |
| metoo | Suppress the deletion of the login name of the user from the recipient list when <br> replying to a message or sending to a group. The default shall be nometoo. |
| onehop | When responding to a message that was originally sent to several recipients, the <br> other recipient addresses are normally forced to be relative to the originating <br> author's machine for the response. This flag disables alteration of the recipients' <br> addresses, improving efficiency in a network where all machines can send directly <br> to all other machines (that is, one hop away). The default shall be noonehop. |
| outfolder $\quad$Cause the files used to record outgoing messages to be located in the directory <br> specified by the folder variable unless the pathname is absolute. The default shall <br> be nooutfolder. See the record variable. |  |
| page | Insert a <form-feed> after each message sent through the pipe created by the pipe <br> command. The default shall be nopage. |

prompt=string
Set the command-mode prompt to string. If string is null or if noprompt is set, no
prompting shall occur. The default shall be to prompt with the string "? ".
quiet Refrain from writing the opening message and version when entering mailx. The
default shall be noquiet.
record=file Record all outgoing mail in the file with the pathname file. The default shall be
norecord. See also outfolder above.
save Enable saving of messages in the dead-letter file on interrupt or delivery error. See
the variable DEAD for the location of the dead-letter file. The default shall be save.
screen=number
Set the number of lines in a screenful of headers for the headers and z commands.
If screen is not specified, a value based on the terminal type identified by the
TERM environment variable, the window size, the baud rate, or some combination
of these shall be used.
sendwait Wait for the background mailer to finish before returning. The default shall be nosendwait.
showto When the sender of the message was the user who is invoking mailx, write the information from the To: line instead of the From: line in the header summary. The default shall be noshowto.
sign=string Set the variable inserted into the text of a message when the ${ }^{\sim}$ a command escape is given. The default shall be nosign. The character sequences ' $\backslash t^{\prime}$ and ' $\backslash n^{\prime}$ shall be recognized in the variable as <tab>s and <newline>s, respectively. (See also ${ }^{\sim} \mathbf{i}$ in Command Escapes in mailx (on page 606).)
Sign=string Set the variable inserted into the text of a message when the ${ }^{\sim} \mathbf{A}$ command escape is given. The default shall be noSign. The character sequences ' $\backslash t^{\prime}$ 'and ' $\backslash n$ ' shall be recognized in the variable as <tab>s and <newline>s, respectively.
toplines=number
Set the number of lines of the message to write with the top command. The default shall be 5 .

```

\section*{Commands in mailx}

The following mailx commands shall be provided. In the following list, header refers to lines from the message header, as shown in the OUTPUT FILES section. Header-line refers to lines within the header that begin with one or more non-white-space characters, immediately followed by a colon and white space and continuing until the next line beginning with a non-white-space character or an empty line. Header-field refers to the portion of a header line prior to the first colon in that line.
For each of the commands listed below, the command can be entered as the abbreviation (those characters in the Synopsis command word preceding the ' ['), the full command (all characters shown for the command word, omitting the '[' and ']'), or any truncation of the full command down to the abbreviation. For example, the exit command (shown as ex[it] in the Synopsis) can be entered as ex, exi, or exit.
The arguments to commands can be quoted, using the following methods:
- An argument can be enclosed between paired double-quotes (" ") or single-quotes (' ' ); any white space, shell word expansion, or backslash characters within the quotes shall be treated literally as part of the argument. A double-quote shall be treated literally within single-quotes and vice versa. These special properties of the quote marks shall occur only when they are paired at the beginning and end of the argument.
- A backslash outside of the enclosing quotes shall be discarded and the following character treated literally as part of the argument.
- An unquoted backslash at the end of a command line shall be discarded and the next line shall continue the command.
Filenames, where expected, shall be subjected to the following transformations, in sequence:
- If the filename begins with an unquoted plus sign, and the folder variable is defined (see the folder variable), the plus sign shall be replaced by the value of the folder variable followed by a slash. If the folder variable is unset or is set to null, the filename shall be unchanged.
- Shell word expansions shall be applied to the filename (see Section 2.6 (on page 37)). If more than a single pathname results from this expansion and the command is expecting one file, the effects are unspecified.

\section*{Declare Aliases}

Synopsis: a[lias] [alias [address...]]
g[roup] [alias [address...]]
Add the given addresses to the alias specified by alias. The names shall be substituted when alias is used as a recipient address specified by the user in an outgoing message (that is, other recipients addressed indirectly through the reply command shall not be substituted in this manner). Mail address alias substitution shall apply only when the alias string is used as a full address; for example, when \(\mathbf{h l j}\) is an alias, hlj@posix.com does not trigger the alias substitution. If no arguments are given, write a listing of the current aliases to standard output. If only an alias argument is given, write a listing of the specified alias to standard output. These listings need not reflect the same order of addresses that were entered.

\section*{Declare Alternatives}

Synopsis: alt[ernates] name...
(See also the metoo variable.) Declare a list of alternative names for the user's login. When responding to a message, these names shall be removed from the list of recipients for the response. The comparison of names shall be in a case-insensitive manner. With no arguments, alternates shall write the current list of alternative names.

\section*{Change Current Directory}
```

Synopsis: cd [directory]
ch[dir] [directory]

```

Change directory. If directory is not specified, the contents of \(H O M E\) shall be used.

\section*{Copy Messages}

Synopsis: C[opy] [file]
c[opy] [msglist] file
C[opy] [msglist]
Copy messages to the file named by the pathname file without marking the messages as saved. Otherwise, it shall be equivalent to the saye command.
In the capitalized form, save the specified messages in a file whose name is derived from the author of the message to be saved, without marking the messages as saved. Otherwise, it shall be equivalent to the Save command.

Delete Messages
Synopsis: d[elete] [msglist]
Mark messages for deletion from the mailbox. The deletions shall not occur until mailx quits (see the quit command) or changes mailboxes (see the folder command). If autoprint is set and there are messages remaining after the delete command, the current message shall be written as described for the print command (see the print command); otherwise, the mailx prompt shall be written.

\section*{Discard Header Fields}

Synopsis: di[scard] [header-field...]
ig[nore] [header-field...]
Suppress the specified header fields when writing messages. Specified header-fields shall be added to the list of suppressed header fields. Examples of header fields to ignore are status and cc. The fields shall be included when the message is saved. The Print and Type commands shall override this command. The comparison of header fields shall be in a case-insensitive manner. If no arguments are specified, write a list of the currently suppressed header fields to standard output; the listing need not reflect the same order of header fields that were entered.
If both retain and discard commands are given, discard commands shall be ignored.

Delete Messages and Display
Synopsis: dp [msglist]
```

    dt [msglist]
    ```

Delete the specified messages as described for the delete command, except that the autoprint variable shall have no effect, and the current message shall be written only if it was set to a message after the last message deleted by the command. Otherwise, an informational message to the effect that there are no further messages in the mailbox shall be written, followed by the mailx prompt.

\section*{Echo a String}

Synopsis: ec[ho] string ...
Echo the given strings, equivalent to the shell echo utility.

\section*{Edit Messages}

Synopsis: e[dit] [msglist]
Edit the given messages. The messages shall be placed in a temporary file and the utility named by the EDITOR variable is invoked to edit each file in sequence. The default EDITOR is unspecified.
The edit command does not modify the contents of those messages in the mailbox.

\section*{Exit \\ Synopsis: ex[it] \\ \(\mathrm{x}[\mathrm{it}]\)}

Exit from mailx without changing the mailbox. No messages shall be saved in the mbox (see also quit).

\section*{Change Folder}

Synopsis: fi[le] [file]
fold[er] [file]
Quit (see the quit command) from the current file of messages and read in the file named by the pathname file. If no argument is given, the name and status of the current mailbox shall be written.
Several unquoted special characters shall be recognized when used as file names, with the following substitutions:
\% The system mailbox for the invoking user.
\%user The system mailbox for user.
\# The previous file.
\& The current mbox.
+ file The named file in the folder directory. (See the folder variable.)
The default file shall be the current mailbox.

\section*{Display List of Folders}

Synopsis: folders
Write the names of the files in the directory set by the folder variable. The command specified by the LISTER environment variable shall be used (see the ENVIRONMENT VARIABLES section).

\section*{Follow Up Specified Messages}

Synopsis: fo[llowup] [message]
F[ollowup] [msglist]
In the lowercase form, respond to a message, recording the response in a file whose name is derived from the author of the message. See also the save and copy commands and outfolder.
In the capitalized form, respond to the first message in the msglist, sending the message to the author of each message in the msglist. The subject line shall be taken from the first message and the response shall be recorded in a file whose name is derived from the author of the first message. See also the Save and Copy commands and outfolder.

Both forms shall override the record variable, if set.

\section*{Display Header Summary for Specified Messages}

Synopsis: f[rom] [msglist]
Write the header summary for the specified messages.

\section*{Display Header Summary}

Synopsis: h[eaders] [message]
Write the page of headers that includes the message specified. If the message argument is not specified, the current message shall not change. However, if the message argument is specified, the current message shall become the message that appears at the top of the page of headers that includes the message specified. The screen variable sets the number of headers per page. See also the \(\mathbf{z}\) command.

\section*{Help}

Synopsis:
```

                                    hel[p]
                            ?
    ```

Write a summary of commands.
Hold Messages
Synopsis: ho[ld] [msglist]
pre[serve] [msglist]

Mark the messages in msglist to be retained in the mailbox when mailx terminates. This shall override any commands that might previously have marked the messages to be deleted. During the current invocation of mailx, only the delete, \(\mathbf{d p}\), or \(\mathbf{d t}\) commands shall remove the preserve marking of a message.

Execute Commands Conditionally
Synopsis: i[f] s|r
mail-commands
el[se]
mail-commands
en[dif]
Execute commands conditionally, where if \(\mathbf{s}\) executes the following mail-commands, up to an else or endif, if the program is in Send Mode, and if \(\mathbf{r}\) shall cause the mail-commands to be executed only in Receive Mode.

\section*{List Available Commands}

Synopsis: \(\quad\) [ist]
Write a list of all commands available. No explanation shall be given.

\section*{Mail a Message \\ Synopsis: m[ail] address...}

Mail a message to the specified addresses or aliases.

\section*{Direct Messages to mbox}

Synopsis: mb[ox] [msglist]
Arrange for the given messages to end up in the mbox save file when mailx terminates normally. See MBOX. See also the exit and quit commands.

\section*{Process Next Specified Message \\ Synopsis: \(\mathrm{n}[\) ext] [message]}

If the current message has not been written (for example, by the print command) since mailx started or since any other message was the current message, behave as if the print command was entered. Otherwise, if there is an undeleted message after the current message, make it the current message and behave as if the print command was entered. Otherwise, an informational message to the effect that there are no further messages in the mailbox shall be written, followed by the mailx prompt. Should the current message location be the result of an immediately preceding hold, mbox, preserve, or touch command, next will act as if the current message has already been written.

Pipe Message
Synopsis: pi[pe] [[msglist] command]
| [[msglist] command]
Pipe the messages through the given command by invoking the command interpreter specified by SHELL with two arguments: -c and command. (See also sh \(-\mathbf{c}\).) The application shall ensure that the command is given as a single argument. Quoting, described previously, can be used to accomplish this. If no arguments are given, the current message shall be piped through the command specified by the value of the cmd variable. If the page variable is set, a <form-feed> shall be inserted after each message.

\section*{Display Message with Headers}

Synopsis: P[rint] [msglist]
T[ype] [msglist]
Write the specified messages, including all header lines, to standard output. Override suppression of lines by the discard, ignore, and retain commands. If crt is set, the messages longer than the number of lines specified by the crt variable shall be paged through the command specified by the PAGER environment variable.

\section*{Display Message}

Synopsis: p[rint] [msglist]
t[ype] [msglist]
Write the specified messages to standard output. If crt is set, the messages longer than the number of lines specified by the crt variable shall be paged through the command specified by the PAGER environment variable.

\section*{Quit}

Synopsis: \(\quad\) [uit]
```

end-of-file

```

Terminate mailx, storing messages that were read in mbox (if the current mailbox is the system mailbox and unless hold is set), deleting messages that have been explicitly saved (unless keepsave is set), discarding messages that have been deleted, and saving all remaining messages in the mailbox.
Reply to a Message List
\begin{tabular}{ll} 
Synopsis: & \(\mathrm{R}[\) eply] [msglist] \\
& \(\mathrm{R}[\) espond] \([\) msglist]
\end{tabular}

Mail a reply message to the sender of each message in the msglist. The subject line shall be formed by concatenating Re:<space> (unless it already begins with that string) and the subject from the first message. If record is set to a filename, the response shall be saved at the end of that file.

See also the flipr variable.
Reply to a Message
Synopsis: r[eply] [message]
\(r\) [espond] [message]
Mail a reply message to all recipients included in the header of the message. The subject line shall be formed by concatenating Re:<space> (unless it already begins with that string) and the subject from the message. If record is set to a filename, the response shall be saved at the end of that file.

See also the flipr variable.

\section*{Retain Header Fields}

Synopsis: ret[ain] [header-field...]
Retain the specified header fields when writing messages. This command shall override all discard and ignore commands. The comparison of header fields shall be in a case-insensitive manner. If no arguments are specified, write a list of the currently retained header fields to standard output; the listing need not reflect the same order of header fields that were entered.

\section*{Save Messages}
\(\begin{array}{lll}\text { Synopsis: } & \mathrm{s}[\text { ave] } & \text { [file] } \\ & \mathrm{s}[\text { ave] } & \text { [msglist] file } \\ & \mathrm{S}[\text { [ave] } & \text { [msglist] }\end{array}\)
Save the specified messages in the file named by the pathname file, or the mbox if the file argument is omitted. The file shall be created if it does not exist; otherwise, the messages shall be appended to the file. The message shall be put in the state saved, and shall behave as specified in the description of the saved state when the current mailbox is exited by the quit or file command.

In the capitalized form, save the specified messages in a file whose name is derived from the author of the first message. The name of the file shall be taken to be the author's name with all network addressing stripped off. See also the Copy, followup, and Followup commands and outfolder variable.

\section*{Set Variables \\ Synopsis: se[t] [name[=[string]]...] [name=number...] [noname ...]}

Define one or more variables called name. The variable can be given a null, string, or numeric value. Quoting and backslash escapes can occur anywhere in string, as described previously, as if the string portion of the argument were the entire argument. The forms name and name= shall be equivalent to name \(=\cdots\) for variables that take string values. The set command without arguments shall write a list of all defined variables and their values. The no name form shall be equivalent to unset name.

\section*{Invoke a Shell}

Synopsis: sh[ell]
Invoke an interactive command interpreter (see also SHELL).
Display Message Size
Synopsis: si[ze] [msglist]
Write the size in bytes of each of the specified messages.

\section*{Read mailx Commands From a File}

Synopsis: so[urce] file
Read and execute commands from the file named by the pathname file and return to command mode.

\section*{Display Beginning of Messages}

Synopsis: to[p] [msglist]
Write the top few lines of each of the specified messages. If the toplines variable is set, it is taken as the number of lines to write. The default shall be 5 .

\section*{Touch Messages}

Synopsis: tou[ch] [msglist]
Touch the specified messages. If any message in msglist is not specifically deleted nor saved in a file, it shall be placed in the mbox upon normal termination. See exit and quit.

Delete Aliases
Synopsis: una[lias] [alias]...
Delete the specified alias names. If a specified alias does not exist, the results are unspecified.

\section*{Undelete Messages}

Synopsis: u[ndelete] [msglist]
Change the state of the specified messages from deleted to read. If autoprint is set, the last message of those restored shall be written. If msglist is not specified, the message shall be selected as follows:
- If there are any deleted messages that follow the current message, the first of these shall be chosen.
- Otherwise, the last deleted message that also precedes the current message shall be chosen.

\section*{Unset Variables \\ Synopsis: uns[et] name...}

Cause the specified variables to be erased.
Edit Message with Full-Screen Editor
Synopsis: V[isual] [msglist]
Edit the given messages with a screen editor. Each message shall be placed in a temporary file, and the utility named by the VISUAL variable shall be invoked to edit each file in sequence. The default editor shall be vi.
The visual command does not modify the contents of those messages in the mailbox.

\section*{Write Messages to a File}

Synopsis: w[rite] [msglist] file
Write the given messages to the file specified by the pathname file, minus the message header. Otherwise, it shall be equivalent to the save command.

\section*{Scroll Header Display}

Synopsis: \(\quad \mathrm{z}[+\mid-]\)
Scroll the header display forward (if ' \({ }^{\prime}\) ' is specified or if no option is specified) or backward (if \({ }^{\prime}{ }^{\prime}\) is specified) one screenful. The number of headers written shall be set by the screen variable.

\section*{Invoke Shell Command}

Synopsis: !command
Invoke the command interpreter specified by SHELL with two arguments: -c and command. (See also \(s h-\mathbf{c}\).) If the bang variable is set, each unescaped occurrence of '!' in command shall be replaced with the command executed by the previous!command or \(!\) command escape.

Null Command
Synopsis: \# comment
This null command (comment) shall be ignored by mailx.

\section*{Display Current Message Number}

Synopsis: =
Write the current message number.

\section*{Command Escapes in mailx}

The following commands can be entered only from input mode, by beginning a line with the escape character (by default, tilde ( \(\sim \wedge)\) ). See the escape variable description for changing this special character. The format for the commands shall be:
```

<escape-character><command-char><separator> [<arguments>]

```
where the <separator> can be zero or more <blank>s.
In the following descriptions, the application shall ensure that the argument command (but not mailx-command) is a shell command string. Any string acceptable to the command interpreter specified by the SHELL variable when it is invoked as SHELL -c command_string shall be valid. The command can be presented as multiple arguments (that is, quoting is not required).
Command escapes that are listed with msglist or mailx-command arguments are invalid in Send Mode and produce unspecified results.
? command Invoke the command interpreter specified by SHELL with two arguments: -c and command; and then return to input mode. If the bang variable is set, each unescaped occurrence of '!' in command shall be replaced with the command executed by the previous! command or \(\because\) command escape.
~. Simulate end-of-file (terminate message input).
: mailx-command, _ _ mailx-command Perform the command-level request.
? Write a summary of command escapes.
~A This shall be equivalent to ~i Sign.
a \(\quad\) This shall be equivalent to \(\sim\) i sign.

~I command Pipe the body of the message through the given command by invoking the command interpreter specified by SHELL with two arguments: -c and command. If the command returns a successful exit status, the standard output of the command shall replace the message. Otherwise, the message shall remain unchanged. If the command fails, an error message giving the exit status shall be written.

\section*{EXIT STATUS}
```

UP When the -e option is specified, the following exit values are returned:
0 Mail was found.
>0 Mail was not found or an error occurred.

```

Otherwise, the following exit values are returned:
0 Successful completion; note that this status implies that all messages were sent, but it gives no assurances that any of them were actually delivered.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

> UP When in input mode (Receive Mode) or Send Mode: UP \(\begin{aligned} & \text { - If an error is encountered processing an input line beginning with a tilde ( }\left(^{\prime}{ }^{\prime} \text { ) character, }\right. \\ & \text { (see Command Escapes in mailx (on page 606)), a diagnostic message shall be written to } \\ & \text { standard error, and the message being composed may be modified, but this condition shall } \\ & \text { not prevent the message from being sent. } \\ & \text { • Other errors shall prevent the sending of the message. }\end{aligned}\) UP When in command mode:
- Default.

\section*{APPLICATION USAGE}

Delivery of messages to remote systems requires the existence of communication paths to such systems. These need not exist.

Input lines are limited to \{LINE_MAX\} bytes, but mailers between systems may impose more severe line-length restrictions. This volume of IEEE Std 1003.1-200x does not place any restrictions on the length of messages handled by mailx, and for delivery of local messages the only limitations should be the normal problems of available disk space for the target mail file. When sending messages to external machines, applications are advised to limit messages to less than 100000 bytes because some mail gateways impose message-length restrictions.
The format of the system mailbox is intentionally unspecified. Not all systems implement system mailboxes as flat files, particularly with the advent of multimedia mail messages. Some system mailboxes may be multiple files, others records in a database. The internal format of the messages themselves is specified with the historical format from Version 7, but only after the messages have been saved in some file other than the system mailbox. This was done so that many historical applications expecting text-file mailboxes are not broken.

Some new formats for messages can be expected in the future, probably including binary data, bit maps, and various multimedia objects. As described here, mailx is not prohibited from handling such messages, but it must store them as text files in secondary mailboxes (unless some extension, such as a variable or command line option, is used to change the stored format). Its method of doing so is implementation-defined and might include translating the data into text file-compatible or readable form or omitting certain portions of the message from the stored output.

The discard and ignore commands are not inverses of the retain command. The retain command discards all header-fields except those explicitly retained. The discard command keeps all header-fields except those explicitly discarded. If headers exist on the retained header list, discard and ignore commands are ignored.

\section*{EXAMPLES}

None.

\section*{RATIONALE}

The standard developers felt strongly that a method for applications to send messages to specific users was necessary. The obvious example is a batch utility, running non-interactively, that wishes to communicate errors or results to a user. However, the actual format, delivery mechanism, and method of reading the message are clearly beyond the scope of this volume of IEEE Std 1003.1-200x.
The intent of this command is to provide a simple, portable interface for sending messages noninteractively. It merely defines a "front-end" to the historical mail system. It is suggested that implementations explicitly denote the sender and recipient in the body of the delivered message. Further specification of formats for either the message envelope or the message itself were deliberately not made, as the industry is in the midst of changing from the current standards to a more internationalized standard and it is probably incorrect, at this time, to require either one.

Implementations are encouraged to conform to the various delivery mechanisms described in the CCITT X. 400 standards or to the equivalent Internet standards, described in Internet Request for Comment (RFC) documents RFC 819, RFC 822, RFC 920, RFC 921, and RFC 1123.
Many historical systems modified each body line that started with From by prefixing the ' \(F\) ' with ' >'. It is unnecessary, but allowed, to do that when the string does not follow a blank line because it cannot be confused with the next header.
The edit and visual commands merely edit the specified messages in a temporary file. They do not modify the contents of those messages in the mailbox; such a capability could be added as an extension, such as by using different command names.
The restriction on a subject line being \{LINE_MAX\}-10 bytes is based on the historical format that consumes 10 bytes for Subject: and the trailing <newline>. Many historical mailers that a message may encounter on other systems are not able to handle lines that long, however.
Like the utilities logger and lp, mailx admittedly is difficult to test. This was not deemed sufficient justification to exclude this utility from this volume of IEEE Std 1003.1-200x. It is also arguable that it is, in fact, testable, but that the tests themselves are not portable.
When mailx is being used by an application that wishes to receive the results as if none of the User Portability Utilities option features were supported, the DEAD environment variable must be set to / \(\mathrm{dev} / \mathrm{null}\). Otherwise, it may be subject to the file creations described in mailx ASYNCHRONOUS EVENTS. Similarly, if the MAILRC environment variable is not set to \(/ \mathrm{dev} / \mathrm{null}\), historical versions of mailx and Mail read initialization commands from a file before processing begins. Since the initialization that a user specifies could alter the contents of messages an application is trying to send, such applications must set MAILRC to / dev/null.
The description of LC_TIME uses "may affect" because many historical implementations do not or cannot manipulate the date and time strings in the incoming mail headers. Some headers found in incoming mail do not have enough information to determine the timezone in which the mail originated, and, therefore, mailx cannot convert the date and time strings into the internal form that then is parsed by routines like strftime() that can take LC_TIME settings into account. Changing all these times to a user-specified format is allowed, but not required.
The paginator selected when PAGER is null or unset is partially unspecified to allow the System V historical practice of using \(p g\) as the default. Bypassing the pagination function, such as by declaring that cat is the paginator, would not meet with the intended meaning of this
description. However, any "portable user" would have to set PAGER explicitly to get his or her preferred paginator on all systems. The paginator choice was made partially unspecified, unlike the VISUAL editor choice (mandated to be vi) because most historical pagers follow a common theme of user input, whereas editors differ dramatically.

Options to specify addresses as cc (carbon copy) or bcc (blind carbon copy) were considered to be format details and were omitted.

A zero exit status implies that all messages were sent, but it gives no assurances that any of them were actually delivered. The reliability of the delivery mechanism is unspecified and is an appropriate marketing distinction between systems.
In order to conform to the Utility Syntax Guidelines, a solution was required to the optional file option-argument to -f. By making file an operand, the guidelines are satisfied and users remain portable. However, it does force implementations to support usage such as:
mailx -fin mymail.box
The no name method of unsetting variables is not present in all historical systems, but it is in System V and provides a logical set of commands corresponding to the format of the display of options from the mailx set command without arguments.

The ask and asksub variables are the names selected by BSD and System V, respectively, for the same feature. They are synonyms in this yolume of IEEE Std 1003.1-200x.

The mailx echo command was not documented in the BSD version and has been omitted here because it is not obviously useful for interactive users.
The default prompt on the System V mailx is a question mark, on BSD Mail an ampersand. Since this volume of IEEE Std 1003.1-200x chose the mailx name, it kept the System V default, assuming that BSD users would not have difficulty with this minor incompatibility (that they can override).
The meanings of \(\mathbf{r}\) and \(\mathbf{R}\) are reversed between System V mailx and SunOS Mail. Once again, since this volume of IEEE Std 1003.1-200x chose the mailx name, it kept the System V default, but allows the SunOS user to achieve the desired results using flipr, an internal variable in System V mailx, although it has not been documented in the SVID.
The indentprefix variable, the retain and unalias commands, and the \({ }^{\sim} \mathbf{F}\) and \({ }^{\sim} \mathbf{M}\) command escapes were adopted from 4.3 BSD Mail.

The version command was not included because no sufficiently general specification of the version information could be devised that would still be useful to a portable user. This command name should be used by suppliers who wish to provide version information about the mailx command.
The "implementation-specific (unspecified) system start-up file" hThe
followed by next (or the default command) would skip the message for which the user had searched.

\section*{FUTURE DIRECTIONS}

None.

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
The description of the EDITOR environment variable is changed to indicate that \(e d\) is the default editor if this variable is not set. In previous issues, this default was not stated explicitly at this point but was implied further down in the text.
The FUTURE DIRECTIONS section is added.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The -F option is added.
- The allnet, debug, and sendwait internal variables are added.
- The C, ec, fo, F, and S mailx commands are added.

In the DESCRIPTION and ENVIRONMENT VARIABLES sections, text stating "HOME directory" is replaced by "directory referred to by the HOME environment variable".
The mailx utility is aligned with the IEEE P1003.2b draft standard, which includes various clarifications to resolve IEEE PASC Interpretations submitted for the ISO POSIX-2: 1993 standard. In particular, the changes here address IEEE PASC Interpretations 1003.2 \#10, \#11, \#103, \#106, \#108, \#114, \#115, \#122, and \#129.

The normative text is reworded to avoid use of the term "must" for application requirements.
The \(T Z\) entry is added to the ENVIRONMENT VARIABLES section.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/32 is applied, applying a change to the EXTENDED DESCRIPTION, raised by IEEE PASC Interpretation 1003.2 \#122, which was overlooked in the first version of IEEE Std 1003.1-200x.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/17 is applied, updating the EXTENDED DESCRIPTION (Internal Variables in mailx). The system start-up file is changed from "implementation-defined" to "unspecified" for consistency with other text in the EXTENDED DESCRIPTION.

Issue 7
SD5-XCU-ERN-69 is applied.
Austin Group Interpretation 1003.1-2001 \#089 is applied, clarifying the effect of the LC_TIME environment variable.

Austin Group Interpretation 1003.1-2001 \#090 is applied, updating the description of the next command.

Shading to indicate support for the User Portability Utilities option is added.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

\section*{DESCRIPTION}

The make utility shall update files that are derived from other files. A typical case is one where object files are derived from the corresponding source files. The make utility examines time relationships and shall update those derived files (called targets) that have modified times earlier than the modified times of the files (called prerequisites) from which they are derived. A description file (makefile) contains a description of the relationships between files, and the commands that need to be executed to update the targets to reflect changes in their prerequisites. Each specification, or rule, shall consist of a target, optional prerequisites, and optional commands to be executed when a prerequisite is newer than the target. There are two types of rule:
1. Inference rules, which have one target name with at least one period (' .') and no slash (' /')
2. Target rules, which can have more than one target name

In addition, make shall have a collection of built-in macros and inference rules that infer prerequisite relationships to simplify maintenance of programs.
To receive exactly the behavior described in this section, the user shall ensure that a portable makefile shall:
- Include the special target. POSIX
- Omit any special target reserved for implementations (a leading period followed by uppercase letters) that has not been specified by this section
The behavior of make is unspecified if either or both of these conditions are not met.

\section*{OPTIONS}

The make utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for Guideline 9.

The following options shall be supported:
-e Cause environment variables, including those with null values, to override macro assignments within makefiles.
-f makefile Specify a different makefile. The argument makefile is a pathname of a description file, which is also referred to as the makefile. A pathname of \({ }^{\prime}{ }^{\prime}\) ' shall denote the standard input. There can be multiple instances of this option, and they shall be processed in the order specified. The effect of specifying the same option-argument more than once is unspecified.
-i Ignore error codes returned by invoked commands. This mode is the same as if the special target .IGNORE were specified without prerequisites.
\(-\mathbf{k} \quad\) Continue to update other targets that do not depend on the current target if a nonignored error occurs while executing the commands to bring a target up-to-date.

\section*{INPUT FILES}

The input file, otherwise known as the makefile, is a text file containing rules, macro definitions, and comments. See the EXTENDED DESCRIPTION section.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of make:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

\section*{MAKEFLAGS}

This variable shall be interpreted as a character string representing a series of option characters to be used as the default options. The implementation shall accept both of the following formats (but need not accept them when intermixed):
- The characters are option letters without the leading hyphens or <blank> separation used on a make utility command line.
- The characters are formatted in a manner similar to a portion of the make utility command line: options are preceded by hyphens and <blank>-separated as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. The macro=value macro definition operands can also be included. The difference between the contents of MAKEFLAGS and the make utility command line is that the contents of the variable shall not be subjected to the word expansions (see Section 2.6 (on page 37)) associated with parsing the command line values.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

\section*{PROJECTDIR}

Provide a directory to be used to search for SCCS files not found in the current directory. In all of the following cases, the search for SCCS files is made in the directory SCCS in the identified directory. If the value of PROJECTDIR begins with a slash, it shall be considered an absolute pathname; otherwise, the value of PROJECTDIR is treated as a user name and that user's initial working directory shall be examined for a subdirectory src or source. If such a directory is found, it shall be used. Otherwise, the value is used as a relative pathname.

If PROJECTDIR is not set or has a null value, the search for SCCS files shall be made in the directory SCCS in the current directory.
The setting of PROJECTDIR affects all files listed in the remainder of this utility description for files with a component named SCCS.
The value of the SHELL environment variable shall not be used as a macro and shall not be modified by defining the SHELL macro in a makefile or on the command line. All other environment variables, including those with null values, shall be used as macros, as defined in Macros (on page 618).

\section*{ASYNCHRONOUS EVENTS}

If not already ignored, make shall trap SIGHUP, SIGTERM, SIGINT, and SIGQUIT and remove the current target unless the target is a directory or the target is a prerequisite of the special target .PRECIOUS or unless one of the \(-\mathbf{n},-\mathbf{p}\), or \(-\mathbf{q}\) options was specified. Any targets removed in this manner shall be reported in diagnostic messages of unspecified format, written to standard error. After this cleanup process, if any, make shall take the standard action for all other signals.

\section*{STDOUT}

The make utility shall write all commands to be executed to standard output unless the -s option was specified, the command is prefixed with an at sign, or the special target .SILENT has either the current target as a prerequisite or has no prerequisites. If make is invoked without any work needing to be done, it shall write a message to standard output indicating that no action was taken. If the \(-\mathbf{t}\) option is present and a file is touched, make shall write to standard output a message of unspecified format indicating that the file was touched, including the filename of the file.

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

Files can be created when the \(-\mathbf{t}\) option is present. Additional files can also be created by the utilities invoked by make.

\section*{EXTENDED DESCRIPTION}

The make utility attempts to perform the actions required to ensure that the specified targets are up-to-date. A target is considered out-of-date if it is older than any of its prerequisites or if it does not exist. The make utility shall treat all prerequisites as targets themselves and recursively ensure that they are up-to-date, processing them in the order in which they appear in the rule. The make utility shall use the modification times of files to determine whether the corresponding targets are out-of-date.
After make has ensured that all of the prerequisites of a target are up-to-date and if the target is out-of-date, the commands associated with the target entry shall be executed. If there are no commands listed for the target, the target shall be treated as up-to-date.

\section*{Makefile Syntax}

A makefile can contain rules, macro definitions (see Macros (on page 618)), and comments. There are two kinds of rules: inference rules and target rules. The make utility shall contain a set of built-in inference rules. If the -r option is present, the built-in rules shall not be used and the suffix list shall be cleared. Additional rules of both types can be specified in a makefile. If a rule is defined more than once, the value of the rule shall be that of the last one specified. Macros can also be defined more than once, and the value of the macro is specified in Macros (on page 618). Comments start with a number sign ('\#') and continue until an unescaped <newline> is reached.

By default, the following files shall be tried in sequence: ./makefile and ./Makefile. If neither XSI ./makefile or ./Makefile are found, other implementation-defined files may also be tried. On XSI-conformant systems, the additional files ./s.makefile, SCCS/s.makefile, ./s.Makefile, and SCCS/s.Makefile shall also be tried.
The -f option shall direct make to ignore any of these default files and use the specified argument as a makefile instead. If the \({ }^{\prime}-^{\prime}\) argument is specified, standard input shall be used.
The term makefile is used to refer to any rules provided by the user, whether in ./makefile or its variants, or specified by the -f option.
The rules in makefiles shall consist of the following types of lines: target rules, including special targets (see Target Rules (on page 616)), inference rules (see Inference Rules (on page 619)), macro definitions (see Macros (on page 618)), empty lines, and comments.
When an escaped <newline> (one preceded by a backslash) is found anywhere in the makefile except in a command line, it shall be replaced, along with any leading white space on the following line, with a single <space>. When an escaped <newline> is found in a command line in a makefile, the command line shall contain the backslash, the <newline>, and the next line, except that the first character of the next line shall not be included if it is a <tab>.

\section*{Makefile Execution}

Makefile command lines shall be processed one at a time by writing the makefile command line to the standard output (unless one of the conditions listed under ' @' suppresses the writing) and executing the command(s) in the line. A <tab> may precede the command to standard output. Command execution shall be as if the makefile command line were the argument to the system () function. The environment for the command being executed shall contain all of the variables in the environment of make.

By default, when make receives a non-zero status from the execution of a command, it shall terminate with an error message to standard error.
Makefile command lines can have one or more of the following prefixes: a hyphen ( \({ }^{\prime} \mathbf{-}^{\prime}\) ), an at sign ('@'), or a plus sign ( \({ }^{\prime}+{ }^{\prime}\) ). These shall modify the way in which make processes the command. When a command is written to standard output, the prefix shall not be included in the output.
- If the command prefix contains a hyphen, or the -i option is present, or the special target .IGNORE has either the current target as a prerequisite or has no prerequisites, any error found while executing the command shall be ignored.
@ If the command prefix contains an at sign and the make utility command line \(-\mathbf{n}\) option is not specified, or the -s option is present, or the special target .SILENT has either the current target as a prerequisite or has no prerequisites, the command shall not be written to standard output before it is executed.
+ If the command prefix contains a plus sign, this indicates a makefile command line that shall be executed even if \(-\mathbf{n},-\mathbf{q}\), or \(-\mathbf{t}\) is specified.

\section*{Target Rules}

Target rules are formatted as follows:
```

target [target...]: [prerequisite...][;command]

```
[<tab>command
<tab>command

Target entries are specified by a <blank>-separated, non-null list of targets, then a colon, then a <blank>-separated, possibly empty list of prerequisites. Text following a semicolon, if any, and all following lines that begin with \(a<t a b>\), are makefile command lines to be executed to update the target. The first non-empty line that does not begin with \(\mathrm{a}<\) tab> or ' \#' shall begin a new entry. An empty or blank line, or a line beginning with ' \(\#\) ' , may begin a new entry.
Applications shall select target names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set). Implementations may allow other characters in target names as extensions. The interpretation of targets containing the characters ' \(\%\) ' and ' "' is implementation-defined.
A target that has prerequisites, but does not have any commands, can be used to add to the prerequisite list for that target. Only one target rule for any given target can contain commands.
Lines that begin with one of the following are called special targets and control the operation of make:
.DEFAULT If the makefile uses this special target, the application shall ensure that it is specified with commands, but without prerequisites. The commands shall be used by make if there are no other rules available to build a target.
.IGNORE Prerequisites of this special target are targets themselves; this shall cause errors from commands associated with them to be ignored in the same manner as specified by the -i option. Subsequent occurrences of .IGNORE shall add to the list of targets ignoring command errors. If no prerequisites are specified, make shall behave as if the -i option had been specified and errors from all commands associated with all targets shall be ignored.
.POSIX The application shall ensure that this special target is specified without prerequisites or commands. If it appears as the first non-comment line in the makefile, make shall process the makefile as specified by this section; otherwise, the behavior of make is unspecified.
.PRECIOUS Prerequisites of this special target shall not be removed if make receives one of the asynchronous events explicitly described in the ASYNCHRONOUS EVENTS section. Subsequent occurrences of .PRECIOUS shall add to the list of precious files. If no prerequisites are specified, all targets in the makefile shall be treated as if specified with .PRECIOUS.
xSI .SCCS_GET The application shall ensure that this special target is specified without prerequisites. If this special target is included in a makefile, the commands specified with this target shall replace the default commands associated with this special target (see Default Rules (on page 622)). The commands specified with this target are used to get all SCCS files that are not found in the current directory.
When source files are named in a dependency list, make shall treat them just like any other target. Because the source file is presumed to be present in the directory, there is no need to add an entry for it to the makefile. When a target has no dependencies, but is present in the directory, make shall assume that that file is up-to-date. If, however, an SCCS file named SCCS/s.source file is found for a target source file, make compares the timestamp of the target file with that of the SCCS/s.source_file to ensure the target is up-to-date. If the target is missing, or if the SCCS file is newer, make shall automatically issue the commands specified for the .SCCS_GET special target to retrieve the most recent version. However, if the target is writable by anyone, make shall not retrieve a new version.
.SILENT Prerequisites of this special target are targets themselves; this shall cause commands associated with them not to be written to the standard output before they are executed. Subsequent occurrences of .SILENT shall add to the list of targets with silent commands. If no prerequisites are specified, make shall behave as if the -s option had been specified and no commands or touch messages associated with any target shall be written to standard output.
.SUFFIXES Prerequisites of .SUFFIXES shall be appended to the list of known suffixes and are used in conjunction with the inference rules (see Inference Rules (on page 619)). If .SUFFIXES does not have any prerequisites, the list of known suffixes shall be cleared.

The special targets .IGNORE, .POSIX, .PRECIOUS, .SILENT, and .SUFFIXES shall be specified without commands.
Targets with names consisting of a leading period followed by the uppercase letters "POSIX" and then any other characters are reserved for future standardization. Targets with names consisting of a leading period followed by one or more uppercase letters are reserved for implementation extensions.

\section*{Macros}

Macro definitions are in the form:
```

string1 = [string2]

```

The macro named string1 is defined as having the value of string2, where string2 is defined as all characters, if any, after the equal sign, up to a comment character (' \#') or an unescaped <newline>. Any <blank>s immediately before or after the equal sign shall be ignored.

Applications shall select macro names from the set of characters consisting solely of periods, underscores, digits, and alphabetics from the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set). A macro name shall not contain an equals sign. Implementations may allow other characters in macro names as extensions.

Macros can appear anywhere in the makefile. Macro expansions using the forms \(\$\) (string1) or \(\$\{\) string 1\(\}\) shall be replaced by string2, as follows:
- Macros in target lines shall be evaluated when the target line is read.
- Macros in makefile command lines shall be evaluated when the command is executed.
- Macros in the string before the equals sign in a macro definition shall be evaluated when the macro assignment is made.
- Macros after the equals sign in a macro definition shall not be evaluated until the defined macro is used in a rule or command, or before the equals sign in a macro definition.
The parentheses or braces are optional if string1 is a single character. The macro \(\$ \$\) shall be replaced by the single character \(\mathbf{~}^{\prime}\). If string1 in a macro expansion contains a macro expansion, the results are unspecified.
Macro expansions using the forms \(\$\) (string \(1[: s u b s t 1=[\) subst2]]) or \(\$\{\) string \(1[: s u b s t 1=[\) subst2] \(]\}\) can be used to replace all occurrences of subst1 with subst2 when the macro substitution is performed. The subst1 to be replaced shall be recognized when it is a suffix at the end of a word in string1 (where a word, in this context, is defined to be a string delimited by the beginning of the line, a <blank>, or a <newline>). If string1 in a macro expansion contains a macro expansion, the results are unspecified.

Macro expansions in string1 of macro definition lines shall be evaluated when read. Macro expansions in string 2 of macro definition lines shall be performed when the macro identified by string1 is expanded in a rule or command.
Macro definitions shall be taken from the following sources, in the following logical order, before the makefile(s) are read.
1. Macros specified on the make utility command line, in the order specified on the command line. It is unspecified whether the internal macros defined in Internal Macros are accepted from this source.
2. Macros defined by the MAKEFLAGS environment variable, in the order specified in the environment variable. It is unspecified whether the internal macros defined in Internal Macros are accepted from this source.
3. The contents of the environment, excluding the MAKEFLAGS and SHELL variables and including the variables with null values.
4. Macros defined in the inference rules built into make.

Macro definitions from these sources shall not override macro definitions from a lowernumbered source. Macro definitions from a single source (for example, the make utility command line, the \(M A K E F L A G S\) environment variable, or the other environment variables)
shall override previous macro definitions from the same source.
Macros defined in the makefile(s) shall override macro definitions that occur before them in the makefile(s) and macro definitions from source 4. If the -e option is not specified, macros defined in the makefile(s) shall override macro definitions from source 3. Macros defined in the makefile(s) shall not override macro definitions from source 1 or source 2.

Before the makefile(s) are read, all of the make utility command line options (except \(-\mathbf{f}\) and \(-\mathbf{p}\) ) and make utility command line macro definitions (except any for the MAKEFLAGS macro), not already included in the MAKEFLAGS macro, shall be added to the MAKEFLAGS macro, quoted in an implementation-defined manner such that when \(M A K E F L A G S\) is read by another instance of the make command, the original macro's value is recovered. Other implementation-defined options and macros may also be added to the MAKEFLAGS macro. If this modifies the value of the MAKEFLAGS macro, or, if the MAKEFLAGS macro is modified at any subsequent time, the \(M A K E F L A G S\) environment variable shall be modified to match the new value of the \(M A K E F L A G S\) macro. The result of setting MAKEFLAGS in the Makefile is unspecified.
Before the makefile(s) are read, all of the make utility command line macro definitions (except the MAKEFLAGS macro or the SHELL macro) shall be added to the environment of make. Other implementation-defined variables may also be added to the environment of make.
The SHELL macro shall be treated specially. It shall be provided by make and set to the pathname of the shell command language interpreter (see sh). The SHELL environment variable shall not affect the value of the SHELL macro. If SHELL is defined in the makefile or is specified on the command line, it shall replace the original value of the SHELL macro, but shall not affect the SHELL environment variable. Other effects of defining SHELL in the makefile or on the command line are implementation-defined.

\section*{Inference Rules}

Inference rules are formatted as follows:
```

target:

```
<tab>command
[<tab>command]
line that does

The application shall ensure that the target portion is a valid target name (see Target Rules (on page 616)) of the form .s2 or .s1.s2 (where .s1 and .s2 are suffixes that have been given as prerequisites of the .SUFFIXES special target and s1 and s2 do not contain any slashes or periods.) If there is only one period in the target, it is a single-suffix inference rule. Targets with two periods are double-suffix inference rules. Inference rules can have only one target before the colon.

The application shall ensure that the makefile does not specify prerequisites for inference rules; no characters other than white space shall follow the colon in the first line, except when creating the empty rule, described below. Prerequisites are inferred, as described below.

Inference rules can be redefined. A target that matches an existing inference rule shall overwrite the old inference rule. An empty rule can be created with a command consisting of simply a semicolon (that is, the rule still exists and is found during inference rule search, but since it is empty, execution has no effect). The empty rule can also be formatted as follows:
rule: ;
where zero or more <blank>s separate the colon and semicolon.
The make utility uses the suffixes of targets and their prerequisites to infer how a target can be made up-to-date. A list of inference rules defines the commands to be executed. By default, make
contains a built-in set of inference rules. Additional rules can be specified in the makefile.
The special target .SUFFIXES contains as its prerequisites a list of suffixes that shall be used by the inference rules. The order in which the suffixes are specified defines the order in which the inference rules for the suffixes are used. New suffixes shall be appended to the current list by specifying a .SUFFIXES special target in the makefile. A .SUFFIXES target with no prerequisites shall clear the list of suffixes. An empty .SUFFIXES target followed by a new .SUFFIXES list is required to change the order of the suffixes.

Normally, the user would provide an inference rule for each suffix. The inference rule to update a target with a suffix .s1 from a prerequisite with a suffix . \(\mathbf{s 2}\) is specified as a target .s2.s1. The internal macros provide the means to specify general inference rules (see Internal Macros (on page 620)).
When no target rule is found to update a target, the inference rules shall be checked. The suffix of the target (.s1) to be built is compared to the list of suffixes specified by the .SUFFIXES special targets. If the . \(\mathbf{s 1}\) suffix is found in .SUFFIXES, the inference rules shall be searched in the order defined for the first .s2.s1 rule whose prerequisite file ( \(\mathbf{\$ *}^{*} . \mathbf{s} 2\) ) exists. If the target is out-of-date with respect to this prerequisite, the commands for that inference rule shall be executed.

If the target to be built does not contain a suffix and there is no rule for the target, the single suffix inference rules shall be checked. The single-suffix inference rules define how to build a target if a file is found with a name that matches the target name with one of the single suffixes appended. A rule with one suffix . \(\mathbf{s} 2\) is the definition of how to build target from target.s2. The other suffix (.s1) is treated as null.
A tilde ( \({ }^{\prime} \sim \prime\) ) in the above rules refers to an SCCS file in the current directory. Thus, the rule .c~. \(\mathbf{o}\) would transform an SCCS C-language source file into an object file (.o). Because the s. of the SCCS files is a prefix, it is incompatible with make's suffix point of view. Hence, the \(\boldsymbol{r}^{\prime} \sim\) ' is a way of changing any file reference into an SCCS file reference.

\section*{Libraries}

If a target or prerequisite contains parentheses, it shall be treated as a member of an archive library. For the lib(member.o) expression lib refers to the name of the archive library and member. \(\mathbf{o}\) to the member name. The application shall ensure that the member is an object file with the .o suffix. The modification time of the expression is the modification time for the member as kept in the archive library; see ar. The .a suffix shall refer to an archive library. The . \(\mathbf{s} \mathbf{2}\). a rule shall be used to update a member in the library from a file with a suffix .s2.

\section*{Internal Macros}

The make utility shall maintain five internal macros that can be used in target and inference rules. In order to clearly define the meaning of these macros, some clarification of the terms target rule, inference rule, target, and prerequisite is necessary.
Target rules are specified by the user in a makefile for a particular target. Inference rules are user-specified or make-specified rules for a particular class of target name. Explicit prerequisites are those prerequisites specified in a makefile on target lines. Implicit prerequisites are those prerequisites that are generated when inference rules are used. Inference rules are applied to implicit prerequisites or to explicit prerequisites that do not have target rules defined for them in the makefile. Target rules are applied to targets specified in the makefile.

Before any target in the makefile is updated, each of its prerequisites (both explicit and implicit) shall be updated. This shall be accomplished by recursively processing each prerequisite. Upon recursion, each prerequisite shall become a target itself. Its prerequisites in turn shall be processed recursively until a target is found that has no prerequisites, at which point the recursion stops. The recursion shall then back up, updating each target as it goes.

In the definitions that follow, the word target refers to one of:
- A target specified in the makefile
- An explicit prerequisite specified in the makefile that becomes the target when make processes it during recursion
- An implicit prerequisite that becomes a target when make processes it during recursion

In the definitions that follow, the word prerequisite refers to one of the following:
- An explicit prerequisite specified in the makefile for a particular target
- An implicit prerequisite generated as a result of locating an appropriate inference rule and corresponding file that matches the suffix of the target
The five internal macros are:
\$@ The \$@ shall evaluate to the full target name of the current target, or the archive filename part of a library archive target. It shall be evaluated for both target and inference rules.

For example, in the .c.a inference rule, \$@ represents the out-of-date .a file to be built. Similarly, in a makefile target rule to build lib.a from file.c, \(\$ @\) represents the out-ofdate lib.a.
\(\$ \% \quad\) The \(\$ \%\) macro shall be evaluated only when the current target is an archive library member of the form libname(member.o). In these cases, \$@ shall evaluate to libname and \(\$ \%\) shall evaluate to member.o. The \(\$ \%\) macro shall be evaluated for both target and inference rules.

For example, in a makefile target rule to build lib.a(file.o), \(\$ \%\) represents file.o, as opposed to \$@, which represents lib.a.
\(\$\) ? The \(\$\) ? macro shall evaluate to the list of prerequisites that are newer than the current target. It shall be evaluated for both target and inference rules.
For example, in a makefile target rule to build prog from file1.o, file2.o, and file3.0, and where prog is not out-of-date with respect to file1.o, but is out-of-date with respect to file2.0 and file3.0, \(\$\) ? represents file2.o and file3.o.
\(\$<\quad\) In an inference rule, the \(\$<\) macro shall evaluate to the filename whose existence allowed the inference rule to be chosen for the target. In the .DEFAULT rule, the \(\$<\) macro shall evaluate to the current target name. The meaning of the \(\$<\) macro shall be otherwise unspecified.
For example, in the .c.a inference rule, \(\$<\) represents the prerequisite .c file.
\$* The \(\$^{*}\) macro shall evaluate to the current target name with its suffix deleted. It shall be evaluated at least for inference rules.

For example, in the .c.a inference rule, \(\$^{*} . o\) represents the out-of-date .o file that corresponds to the prerequisite .c file.

Each of the internal macros has an alternative form. When an uppercase ' \(D^{\prime}\) or \({ }^{\prime} F^{\prime}\) is appended to any of the macros, the meaning shall be changed to the directory part for ' \(\mathrm{D}^{\prime}\) and filename part for ' \(\mathrm{F}^{\prime}\). The directory part is the path prefix of the file without a trailing slash; for the current directory, the directory part is ' .'. When the \(\$\) ? macro contains more than one prerequisite filename, the \(\$(? \mathrm{D})\) and \(\$(? \mathrm{~F})\) (or \(\$\{? \mathrm{D}\}\) and \(\$\{? \mathrm{~F}\}\) ) macros expand to a list of directory name parts and filename parts respectively.
For the target lib(member.o) and the s2.a rule, the internal macros shall be defined as:
```

    $(GET) $(GFLAGS) -p $< > $*.f
    $(FC) $(FFLAGS) $(LDFLAGS) -o $@ $*.f
    .sh ~
\$(GET) \$(GFLAGS) -p \$< > \$*.sh
cp \$*.sh \$@
chmod a+x \$@

```
```

\section*{EXIT STATUS}

When the \(-\mathbf{q}\) option is specified, the make utility shall exit with one of the following values:
0 Successful completion.
1 The target was not up-to-date.
\(>1\) An error occurred.
When the \(-\mathbf{q}\) option is not specified, the make utility shall exit with one of the following values:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.

\section*{APPLICATION USAGE}

If there is a source file (such as ./source.c) and there are two SCCS files corresponding to it (./s.source.c and ./SCCS/s.source.c), on XSI-conformant systems make uses the SCCS file in the current directory. However, users are advised to use the underlying SCCS utilities (admin, delta, get, and so on) or the sccs utility for all source files in a given directory. If both forms are used for a given source file, future developers are very likely to be confused.
It is incumbent upon portable makefiles to specify the .POSIX special target in order to guarantee that they are not affected by local extensions.
The \(-\mathbf{k}\) and \(\mathbf{- S}\) options are both present so that the relationship between the command line, the MAKEFLAGS variable, and the makefile can be controlled precisely. If the \(\mathbf{k}\) flag is passed in MAKEFLAGS and a command is of the form:
```

\$(MAKE) -S foo

```
then the default behavior is restored for the child make.
When the \(\mathbf{- n}\) option is specified, it is always added to MAKEFLAGS. This allows a recursive make \(-\mathbf{n}\) target to be used to see all of the action that would be taken to update target.
Because of widespread historical practice, interpreting a '\#' number sign inside a variable as the start of a comment has the unfortunate side effect of making it impossible to place a number sign in a variable, thus forbidding something like:
CFLAGS \(=\) "-D COMMENT_CHAR='\#'"

Many historical make utilities stop chaining together inference rules when an intermediate target is nonexistent. For example, it might be possible for a make to determine that both .y.c and .c.o could be used to convert a .y to a .o. Instead, in this case, make requires the use of a .y.o rule.
The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other parts of this volume of IEEE Std 1003.1-200x. The default rules include rules for optional commands in this volume of IEEE Std 1003.1-200x. Only rules pertaining to commands that are provided are needed in an implementation's default set.

Macros used within other macros are evaluated when the new macro is used rather than when the new macro is defined. Therefore:
```

MACRO = value1
NEW = \$(MACRO)
MACRO = value2
target:
echo \$(NEW)

```
would produce value 2 and not value1 since NEW was not expanded until it was needed in the echo command line.

Some historical applications have been known to intermix target_name and macro=name operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, although some backwards-compatibility support may be included in some implementations.
 inference rules, the description of \(\$<\) and \(\$\) ? seem similar. However, an example shows the minor difference. In a makefile containing:
foo.o: foo.h
if foo.h is newer than foo.o, yet foo.c is older than foo.o, the built-in rule to make foo.o from foo.c is used, with \(\$<\) equal to foo.c and \(\$\) ? equal to foo.h. If foo.c is also newer than foo.o, \(\$<\) is equal to foo.c and \(\$\) ? is equal to foo.h foo.c.

\section*{EXAMPLES}
1. The following command:
make
makes the first target found in the makefile.
2. The following command:
make junk
makes the target junk.
3. The following makefile says that pgm depends on two files, a.o and b.o, and that they in turn depend on their corresponding source files (a.c and b.c), and a common file incl.h:
```

pgm: a.o b.o
c99 a.o b.o -o pgm
a.o: incl.h a.c
c99 -c a.c
b.o: incl.h b.c
c99 -c b.c

```
4. An example for making optimized .o files from .c files is:
```

.c.o:
c99 -c -O \$*.c
or:
.c.○:
c99 -c -0 \$<

```
5. The most common use of the archive interface follows. Here, it is assumed that the source files are all C-language source:
```

lib: lib(file1.o) lib(file2.o) lib(file3.o)
@echo lib is now up-to-date

```

The .c.a rule is used to make file1.0, file2.o, and file3.o and insert them into lib.
The treatment of escaped <newline>s throughout the makefile is historical practice. For example, the inference rule:
.c.o\}
:
works, and the macro:
```

f= bar baz\
biz
a:
echo ==\$f==
echoes "==bar baz biz==".

```
If \$? were:
/usr/include/stdio.h /usr/include/unistd.h foo.h
then \(\$(? \mathrm{D})\) would be:
```

/usr/include /usr/include

```
and \(\$(? F)\) would be:
stdio.h unistd.h foo.h
6. The contents of the built-in rules can be viewed by running:
```

make -p -f /dev/null 2>/dev/null

```

\section*{RATIONALE}

The make utility described in this volume of IEEE Std 1003.1-200x is intended to provide the means for changing portable source code into executables that can be run on an IEEE Std 1003.1-200x-conforming system. It reflects the most common features present in System V and BSD makes.

Historically, the make utility has been an especially fertile ground for vendor and research organization-specific syntax modifications and extensions. Examples include:
- Syntax supporting parallel execution (such as from various multi-processor vendors, GNU, and others)
- Additional "operators" separating targets and their prerequisites (System V, BSD, and others)
- Specifying that command lines containing the strings "\$ \{MAKE\}" and "\$(MAKE)" are executed when the \(-\mathbf{n}\) option is specified (GNU and System V)
- Modifications of the meaning of internal macros when referencing libraries (BSD and others)
- Using a single instance of the shell for all of the command lines of the target (BSD and others)
- Allowing spaces as well as tabs to delimit command lines (BSD)
- Adding C preprocessor-style "include" and "ifdef" constructs (System V, GNU, BSD, and others)
- Remote execution of command lines (Sprite and others)
- Specifying additional special targets (BSD, System V, and most others)

Additionally, many vendors and research organizations have rethought the basic concepts of make, creating vastly extended, as well as completely new, syntaxes. Each of these versions of make fulfills the needs of a different community of users; it is unreasonable for this volume of IEEE Std 1003.1-200x to require behavior that would be incompatible (and probably inferior) to historical practice for such a community.

In similar circumstances, when the industry has enough sufficiently incompatible formats as to make them irreconcilable, this volume of IEEE Std 1003.1-200x has followed one or both of two courses of action. Commands have been renamed (cksum, echo, and pax) and/or command line options have been provided to select the desired behavior (grep, od, and pax).
Because the syntax specified for the make utility is, by and large, a subset of the syntaxes accepted by almost all versions of make, it was decided that it would be counter-productive to change the name. And since the makefile itself is a basic unit of portability, it would not be completely effective to reserve a new option letter, such as make \(\mathbf{-} \mathbf{P}\), to achieve the portable behavior. Therefore, the special target. POSIX was added to the makefile, allowing users to specify "standard" behavior. This special target does not preclude extensions in the make utility, nor does it preclude such extensions being used by the makefile specifying the target; it does, however, preclude any extensions from being applied that could alter the behavior of previously valid syntax; such extensions must be controlled via command line options or new special targets. It is incumbent upon portable makefiles to specify the .POSIX special target in order to guarantee that they are not affected by local extensions.

The portable version of make described in this reference page is not intended to be the state-of-the-art software generation tool and, as such, some newer and more leading-edge features have not been included. An attempt has been made to describe the portable makefile in a manner that does not preclude such extensions as long as they do not disturb the portable behavior described here.

When the \(\mathbf{- n}\) option is specified, it is always added to \(M A K E F L A G S\). This allows a recursive make \(-\mathbf{n}\) target to be used to see all of the action that would be taken to update target.

The definition of MAKEFLAGS allows both the System V letter string and the BSD command line formats. The two formats are sufficiently different to allow implementations to support both without ambiguity.
Early proposals stated that an "unquoted" number sign was treated as the start of a comment. The make utility does not pay any attention to quotes. A number sign starts a comment regardless of its surroundings.
The text about "other implementation-defined pathnames may also be tried" in addition to ./makefile and ./Makefile is to allow such extensions as SCCS/s.Makefile and other variations. It was made an implementation-defined requirement (as opposed to unspecified behavior) to
highlight surprising implementations that might select something unexpected like /etc/Makefile. XSI-conformant systems also try ./s.makefile, SCCS/s.makefile, ./s.Makefile, and SCCS/s.Makefile.

Early proposals contained the macro NPROC as a means of specifying that make should use \(n\) processes to do the work required. While this feature is a valuable extension for many systems, it is not common usage and could require other non-trivial extensions to makefile syntax. This extension is not required by this volume of IEEE Std 1003.1-200x, but could be provided as a compatible extension. The macro PARALLEL is used by some historical systems with essentially the same meaning (but without using a name that is a common system limit value). It is suggested that implementors recognize the existing use of NPROC and/or PARALLEL as extensions to make.
The default rules are based on System V. The default \(\mathbf{C C}=\) value is \(c 99\) instead of \(c c\) because this volume of IEEE Std 1003.1-200x does not standardize the utility named cc. Thus, every conforming application would be required to define \(\mathbf{C C}=c 99\) to expect to run. There is no advantage conferred by the hope that the makefile might hit the "preferred" compiler because this cannot be guaranteed to work. Also, since the portable makescript can only use the c99 options, no advantage is conferred in terms of what the script can do. It is a quality-ofimplementation issue as to whether \(c 99\) is as valuable as \(c c\).

The -d option to make is frequently used to produce debugging information, but is too implementation-defined to add to this volume of IEEE Std 1003.1-200x.

The - \(\mathbf{p}\) option is not passed in MAKEFLAGS on most historical implementations and to change this would cause many implementations to break without sufficiently increased portability.
Commands that begin with a plus sign ( \({ }^{\prime}+^{\prime}\) ) are executed even if the \(-\mathbf{n}\) option is present. Based on the GNU version of make, the behavior of \(-\mathbf{n}\) when the plus-sign prefix is encountered has been extended to apply to \(-\mathbf{q}\) and \(-\mathbf{t}\) as well. Howeyer, the System \(V\) convention of forcing command execution with \(\mathbf{- n}\) when the command line of a target contains either of the strings "\$ (MAKE) " or "\$\{MAKE\}" has not been adopted. This functionality appeared in early proposals, but the danger of this approach was pointed out with the following example of a portion of a makefile:
```

subdir:
cd subdir; rm all_the_files; \$(MAKE)

```

The loss of the System V behavior in this case is well-balanced by the safety afforded to other makefiles that were not aware of this situation. In any event, the command line plus-sign prefix can provide the desired functionality.
The double colon in the target rule format is supported in BSD systems to allow more than one target line containing the same target name to have commands associated with it. Since this is not functionality described in the SVID or XPG3 it has been allowed as an extension, but not mandated.
The default rules are provided with text specifying that the built-in rules shall be the same as if the listed set were used. The intent is that implementations should be able to use the rules without change, but will be allowed to alter them in ways that do not affect the primary behavior.

The best way to provide portable makefiles is to include all of the rules needed in the makefile itself. The rules provided use only features provided by other portions of this volume of IEEE Std 1003.1-200x. The default rules include rules for optional commands in this volume of IEEE Std 1003.1-200x. Only rules pertaining to commands that are provided are needed in the default set of an implementation.
One point of discussion was whether to drop the default rules list from this volume of IEEE Std 1003.1-200x. They provide convenience, but do not enhance portability of applications.

The prime benefit is in portability of users who wish to type make command and have the command build from a command.c file.

The historical \(M A K E S H E L L\) feature was omitted. In some implementations it is used to let a user override the shell to be used to run make commands. This was confusing; for a portable make, the shell should be chosen by the makefile writer or specified on the make command line and not by a user running make.

The make utilities in most historical implementations process the prerequisites of a target in left-to-right order, and the makefile format requires this. It supports the standard idiom used in many makefiles that produce yacc programs; for example:
foo: y.tab.o lex.o main.o
\$ (CC) \$ (CFLAGS) -o \$@ t.tab.o lex.o main.o
In this example, if make chose any arbitrary order, the lex.o might not be made with the correct y.tab.h. Although there may be better ways to express this relationship, it is widely used historically. Implementations that desire to update prerequisites in parallel should require an explicit extension to make or the makefile format to accomplish it, as described previously.
The algorithm for determining a new entry for target rules is partially unspecified. Some historical makes allow blank, empty, or comment lines within the collection of commands marked by leading <tab>s. A conforming makefile must ensure that each command starts with a <tab>, but implementations are free to ignore blank, empty, and comment lines without triggering the start of a new entry.
The ASYNCHRONOUS EVENTS section includes having SIGTERM and SIGHUP, along with the more traditional SIGINT and SIGQUIT, remove the current target unless directed not to do so. SIGTERM and SIGHUP were added to parallel other utilities that have historically cleaned up their work as a result of these signals. When make receives any signal other than SIGQUIT, it is required to resend itself the signal it received so that it exits with a status that reflects the signal. The results from SIGQUIT are partially unspecified because, on systems that create core files upon receipt of SIGQUIT, the core from make would conflict with a core file from the command that was running when the SIGQUIT arrived. The main concern was to prevent damaged files from appearing up-to-date when make is rerun.

The .PRECIOUS special target was extended to affect all targets globally (by specifying no prerequisites). The .IGNORE and .SILENT special targets were extended to allow prerequisites; it was judged to be more useful in some cases to be able to turn off errors or echoing for a list of targets than for the entire makefile. These extensions to make in System V were made to match historical practice from the BSD make.
Macros are not exported to the environment of commands to be run. This was never the case in any historical make and would have serious consequences. The environment is the same as the environment to make except that MAKEFLAGS and macros defined on the make command line are added.

Some implementations do not use system () for all command lines, as required by the portable makefile format; as a performance enhancement, they select lines without shell metacharacters for direct execution by execve( ). There is no requirement that system () be used specifically, but merely that the same results be achieved. The metacharacters typically used to bypass the direct execve ( ) execution have been any of:

The default in some advanced versions of make is to group all the command lines for a target and execute them using a single shell invocation; the System V method is to pass each line individually to a separate shell. The single-shell method has the advantages in performance and the lack of a requirement for many continued lines. However, converting to this newer method has caused portability problems with many historical makefiles, so the behavior with the POSIX
makefile is specified to be the same as that of System V. It is suggested that the special target .ONESHELL be used as an implementation extension to achieve the single-shell grouping for a target or group of targets.
Novice users of make have had difficulty with the historical need to start commands with a <tab>. Since it is often difficult to discern differences between <tab>s and <space>s on terminals or printed listings, confusing bugs can arise. In early proposals, an attempt was made to correct this problem by allowing leading <blank>s instead of <tab>s. However, implementors reported many makefiles that failed in subtle ways following this change, and it is difficult to implement a make that unambiguously can differentiate between macro and command lines. There is extensive historical practice of allowing leading spaces before macro definitions. Forcing macro lines into column 1 would be a significant backwards-compatibility problem for some makefiles. Therefore, historical practice was restored.
The System V INCLUDE feature was considered, but not included. This would treat a line that began in the first column and contained INCLUDE <filename> as an indication to read <filename> at that point in the makefile. This is difficult to use in a portable way, and it raises concerns about nesting levels and diagnostics. System V, BSD, GNU, and others have used different methods for including files.
The System V dynamic dependency feature was not included. It would support:
```

cat: \$\$@.c
```
that would expand to;
cat: cat.c
This feature exists only in the new version of System V make and, while useful, is not in wide usage. This means that macros are expanded twice for prerequisites: once at makefile parse time and once at target update time.
Consideration was given to adding metarules to the POSIX make. This would make \%.o: \%.c the same as .c.o:. This is quite useful and available from some vendors, but it would cause too many changes to this make to support. It would have introduced rule chaining and new substitution rules. However, the rules for target names have been set to reserve the ${ }^{\prime \prime}$ ' and ${ }^{\prime \prime}$ " characters. These are traditionally used to implement metarules and quoting of target names, respectively. Implementors are strongly encouraged to use these characters only for these purposes.
A request was made to extend the suffix delimiter character from a period to any character. The metarules feature in newer makes solves this problem in a more general way. This volume of IEEE Std 1003.1-200x is staying with the more conservative historical definition.
The standard output format for the $-\mathbf{p}$ option is not described because it is primarily a debugging option and because the format is not generally useful to programs. In historical implementations the output is not suitable for use in generating makefiles. The $-\mathbf{p}$ format has been variable across historical implementations. Therefore, the definition of $-\mathbf{p}$ was only to provide a consistently named option for obtaining make script debugging information.
Some historical implementations have not cleared the suffix list with -r.
Implementations should be aware that some historical applications have intermixed target_name and macro=value operands on the command line, expecting that all of the macros are processed before any of the targets are dealt with. Conforming applications do not do this, but some backwards-compatibility support may be warranted.
Empty inference rules are specified with a semicolon command rather than omitting all commands, as described in an early proposal. The latter case has no traditional meaning and is reserved for implementation extensions, such as in GNU make.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Chapter 2 (on page 29), ar, c99, get, lex, sccs, sh, yacc, the System Interfaces volume of IEEE Std 1003.1-200x, exec, system ()

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.

## Issue 6

This utility is marked as part of the Software Development Utilities option.
The Open Group Corrigendum U029/1 is applied, correcting a typographical error in the SPECIAL TARGETS section.
In the ENVIRONMENT VARIABLES section, the PROJECTDIR description is updated from "otherwise, the home directory of a user of that name is examined" to "otherwise, the value of PROJECTDIR is treated as a user name and that user's initial working directory is examined".

It is specified whether the command line is related to the makefile or to the make command, and the macro processing rules are updated to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
PASC Interpretation 1003.2 \#193 is applied.

## Issue 7

SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
man - display system documentation

## SYNOPSIS

```
man [-k] name...
```

## DESCRIPTION

The man utility shall write information about each of the name operands. If name is the name of a standard utility, man at a minimum shall write a message describing the syntax used by the standard utility, its options, and operands. If more information is available, the man utility shall provide it in an implementation-defined manner.
An implementation may provide information for values of name other than the standard utilities. Standard utilities that are listed as optional and that are not supported by the implementation either shall cause a brief message indicating that fact to be displayed or shall cause a full display of information as described previously.

## OPTIONS

The man utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-k Interpret name operands as keywords to be used in searching a utilities summary database that contains a brief purpose entry for each standard utility and write lines from the summary database that match any of the keywords. The keyword search shall produce results that are the equivalent of the output of the following command:

This assumes that the summary-database is a text file with a single entry per line; this organization is not required and the example using grep -Ei is merely illustrative of the type of search intended. The purpose entry to be included in the database shall consist of a terse description of the purpose of the utility.

OPERANDS
The following operand shall be supported:
name A keyword or the name of a standard utility. When $-\mathbf{k}$ is not specified and name does not represent one of the standard utilities, the results are unspecified.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of man:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and in the summary database). The value of LC_CTYPE need not affect the format of the information written about the name operands.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PAGER Determine an output filtering command for writing the output to a terminal. Any string acceptable as a command_string operand to the sh-c command shall be valid. When standard output is a terminal device, the reference page output shall be piped through the command. If the PAGER variable is null or not set, the command shall be either more or another paginator utility documented in the system documentation.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The man utility shall write text describing the syntax of the utility name, its options and its operands, or, when $-\mathbf{k}$ is specified, lines from the summary database. The format of this text is implementation-defined.

## STDERR

The standard error shall be used for diagnostic messages, and may also be used for informational messages of unspecified format.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

It is recognized that the man utility is only of minimal usefulness as specified. The opinion of the standard developers was strongly divided as to how much or how little information man should be required to provide. They considered, however, that the provision of some portable way of accessing documentation would aid user portability. The arguments against a fuller specification were:

- Large quantities of documentation should not be required on a system that does not have excess disk space.
- The current manual system does not present information in a manner that greatly aids user portability.
- A "better help system" is currently an area in which vendors feel that they can add value to their POSIX implementations.

The -f option was considered, but due to implementation differences, it was not included in this volume of IEEE Std 1003.1-200x.

The description was changed to be more specific about what has to be displayed for a utility. The standard developers considered it insufficient to allow a display of only the synopsis without giving a short description of what each option and operand does.
The "purpose" entry to be included in the database can be similar to the section title (less the numeric prefix) from this volume of IEEE Std 1003.1-200x for each utility. These titles are similar to those used in historical systems for this purpose.
See mailx for rationale concerning the default paginator.
The caveat in the LC_CTYPE description was added because it is not a requirement that an implementation provide reference pages for all of its supported locales on each system; changing LC_CTYPE does not necessarily translate the reference page into another language. This is equivalent to the current state of LC_MESSAGES in IEEE Std 1003.1-200x—locale-specific messages are not yet a requirement.

The historical MANPATH variable is not included in POSIX because no attempt is made to specify naming conventions for reference page files, nor even to mandate that they are files at all. On some implementations they could be a true database, a hypertext file, or even fixed strings within the man executable. The standard developers considered the portability of reference pages to be outside their scope of work. However, users should be aware that MANPATH is implemented on a number of historical systems and that it can be used to tailor the search pattern for reference pages from the various categories (utilities, functions, file formats, and so on) when the system administrator reveals the location and conventions for reference pages on the system.

The keyword search can rely on at least the text of the section titles from these utility descriptions, and the implementation may add more keywords. The term "section titles" refers to the strings such as:
man - Display system documentation
ps - Report process status

Issue 5
The FUTURE DIRECTIONS section is added.

## Issue 7

Austin Group Interpretation 1003.1-2001 \#108 is applied, clarifying that informational messages may appear on standard error.

NAME
mesg - permit or deny messages

## SYNOPSIS

```
mesg [y|n]
```

## DESCRIPTION

The mesg utility shall control whether other users are allowed to send messages via write, talk, or other utilities to a terminal device. The terminal device affected shall be determined by searching for the first terminal in the sequence of devices associated with standard input, standard output, and standard error, respectively. With no arguments, mesg shall report the current state without changing it. Processes with appropriate privileges may be able to send messages to the terminal independent of the current state.

## OPTIONS

None.

## OPERANDS

The following operands shall be supported in the POSIX locale:
$y \quad$ Grant permission to other users to send messages to the terminal device.
$n \quad$ Deny permission to other users to send messages to the terminal device.

## STDIN

Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of mesg:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written (by mesg) to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If no operand is specified, mesg shall display the current terminal state in an unspecified format.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## None.

## EXIT STATUS

The following exit values shall be returned:
0 Receiving messages is allowed.
1 Receiving messages is not allowed.
$>1$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The mechanism by which the message status of the terminal is changed is unspecified. Therefore, unspecified actions may cause the status of the terminal to change after mesg has successfully completed. These actions may include, but are not limited to: another invocation of the mesg utility, login procedures; invocation of the stty utility, invocation of the chmod utility or chmod () function, and so on.

## EXAMPLES

None.

## RATIONALE

The terminal changed by mesg is that associated with the standard input, output, or error, rather than the controlling terminal for the session. This is because users logged in more than once should be able to change any of their login terminals without having to stop the job running in those sessions. This is not a security problem involving the terminals of other users because appropriate privileges would be required to affect the terminal of another user.

The method of checking each of the first three file descriptors in sequence until a terminal is found was adopted from System V.
The file /dev/tty is not specified for the terminal device because it was thought to be too restrictive. Typical environment changes for the $n$ operand are that write permissions are removed for others and group from the appropriate device. It was decided to leave the actual description of what is done as unspecified because of potential differences between implementations.
The format for standard output is unspecified because of differences between historical implementations. This output is generally not useful to shell scripts (they can use the exit status), so exact parsing of the output is unnecessary.

## FUTURE DIRECTIONS

None.
SEE ALSO
talk, write

## CHANGE HISTORY

First released in Issue 2.

## Issue 6

This utility is marked as part of the User Portability Utilities option.
Issue 7
The mesg utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME
mkdir — make directories

## SYNOPSIS

```
    mkdir [-p] [-m mode] dir...
```

## DESCRIPTION

The mkdir utility shall create the directories specified by the operands, in the order specified.
For each dir operand, the mkdir utility shall perform actions equivalent to the mkdir() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

1. The dir operand is used as the path argument.
2. The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO is used as the mode argument. (If the -m option is specified, the value of the mkdir() mode argument is unspecified, but the directory shall at no time have permissions less restrictive than the -m mode option-argument.)
OPTIONS
The mkdir utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-m mode Set the file permission bits of the newly-created directory to the specified mode value. The mode option-argument shall be the same as the mode operand defined for the chmod utility. In the symbolic_mode strings, the op characters '+' and '_' shall be interpreted relative to an assumed initial mode of $a=r w x ;$ ' + ' shall add permissions to the default mode, ' ${ }^{\prime}$ ' shall delete permissions from the default mode.
-p Create any missing intermediate pathname components.
For each dir operand that does not name an existing directory, effects equivalent to those caused by the following command shall occur:

```
mkdir -p -m $(umask -S),u+wx $(dirname dir) &&
```

mkdir [-m mode] dir
where the -m mode option represents that option supplied to the original invocation of mkdir, if any.
Each dir operand that names an existing directory shall be ignored without error.

## OPERANDS

The following operand shall be supported:
dir A pathname of a directory to be created.
STDIN
Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of mkdir:
$L A N G \quad$ Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.
EXIT STATUS
The following exit values shall be returned:
0 All the specified directories were created successfully or the $-\mathbf{p}$ option was specified and all the specified directories now exist.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The default file mode for directories is $a=r w x$ (777 on most systems) with selected permissions removed in accordance with the file mode creation mask. For intermediate pathname components created by mkdir, the mode is the default modified by $u+w x$ so that the subdirectories can always be created regardless of the file mode creation mask; if different ultimate permissions are desired for the intermediate directories, they can be changed afterwards with chmod.

Note that some of the requested directories may have been created even if an error occurs.

## EXAMPLES

None.

## RATIONALE

The System V -m option was included to control the file mode.
The System V -p option was included to create any needed intermediate directories and to complement the functionality provided by rmdir for removing directories in the path prefix as they become empty. Because no error is produced if any path component already exists, the $-\mathbf{p}$ option is also useful to ensure that a particular directory exists.

The functionality of mkdir is described substantially through a reference to the mkdir () function in the System Interfaces volume of IEEE Std 1003.1-200x. For example, by default, the mode of the directory is affected by the file mode creation mask in accordance with the specified behavior of the mkdir () function. In this way, there is less duplication of effort required for describing details of the directory creation.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 7
SD5-XCU-ERN-56 is applied, aligning the $-\mathbf{m}$ option with the IEEE P1003.2b draft standard to clarify an ambiguity.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
mkfifo — make FIFO special files

## SYNOPSIS

```
    mkfifo [-m mode] file...
```

## DESCRIPTION

The mkfifo utility shall create the FIFO special files specified by the operands, in the order specified.

For each file operand, the mkfifo utility shall perform actions equivalent to the mkfifo() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

1. The file operand is used as the path argument.
2. The value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH is used as the mode argument. (If the -m option is specified, the value of the mkfifo() mode argument is unspecified, but the FIFO shall at no time have permissions less restrictive than the $-\mathbf{m}$ mode option-argument.)

## OPTIONS

The mkfifo utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-m mode Set the file permission bits of the newly-created FIFO to the specified mode value. The mode option-argument shall be the same as the mode operand defined for the chmod utility. In the symbolic_mode strings, the op characters ' + ' and ' -' shall be interpreted relative to an assumed initial mode of $a=r w$.

## OPERANDS

The following operand shall be supported:
file A pathname of the FIFO special file to be created.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of mkfifo:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.
EXIT STATUS
The following exit values shall be returned:
0 All the specified FIFO special files were created successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

This utility was added to permit shell applications to create FIFO special files.
The -m option was added to control the file mode, for consistency with the similar functionality provided by the mkdir utility.

Early proposals included a -p option similar to the mkdir $-\mathbf{p}$ option that created intermediate directories leading up to the FIFO specified by the final component. This was removed because it is not commonly needed and is not common practice with similar utilities.
The functionality of $m k f i f o$ is described substantially through a reference to the $m k f i f o()$ function in the System Interfaces volume of IEEE Std 1003.1-200x. For example, by default, the mode of the FIFO file is affected by the file mode creation mask in accordance with the specified behavior of the $m k f i f o()$ function. In this way, there is less duplication of effort required for describing details of the file creation.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 3.

NAME
more - display files on a page-by-page basis

## SYNOPSIS

UP more [-ceisu] [-n number] [-p command] [-t tagstring] [file...]

## DESCRIPTION

The more utility shall read files and either write them to the terminal on a page-by-page basis or filter them to standard output. If standard output is not a terminal device, all input files shall be copied to standard output in their entirety, without modification, except as specified for the -s option. If standard output is a terminal device, the files shall be written a number of lines (one screenful) at a time under the control of user commands. See the EXTENDED DESCRIPTION section.
Certain block-mode terminals do not have all the capabilities necessary to support the complete more definition; they are incapable of accepting commands that are not terminated with a <newline>. Implementations that support such terminals shall provide an operating mode to more in which all commands can be terminated with a <newline> on those terminals. This mode:

- Shall be documented in the system documentation
- Shall, at invocation, inform the user of the terminal deficiency that requires the <newline> usage and provide instructions on how this warning can be suppressed in future invocations
- Shall not be required for implementations supporting only fully capable terminals
- Shall not affect commands already requiring <newline>s
- Shall not affect users on the capable terminals from using more as described in this volume of IEEE Std 1003.1-200x

## OPTIONS

The more utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that ' + ' may be recognized as an option delimiter as well as ' - '.

The following options shall be supported:
-c If a screen is to be written that has no lines in common with the current screen, or more is writing its first screen, more shall not scroll the screen, but instead shall redraw each line of the screen in turn, from the top of the screen to the bottom. In addition, if more is writing its first screen, the screen shall be cleared. This option may be silently ignored on devices with insufficient terminal capabilities.
-e By default, more shall exit immediately after writing the last line of the last file in the argument list. If the -e option is specified:

1. If there is only a single file in the argument list and that file was completely displayed on a single screen, more shall exit immediately after writing the last line of that file.
2. Otherwise, more shall exit only after reaching end-of-file on the last file in the argument list twice without an intervening operation. See the EXTENDED DESCRIPTION section.

## STDIN

The standard input shall be used only if no file operands are specified, or if a file operand is ${ }^{\prime} \mathbf{-}^{\prime}$.

## INPUT FILES

The input files being examined shall be text files. If standard output is a terminal, standard error shall be used to read commands from the user. If standard output is a terminal, standard error is not readable, and command input is needed, more may attempt to obtain user commands from the controlling terminal (for example, /dev/tty); otherwise, more shall terminate with an error indicating that it was unable to read user commands. If standard output is not a terminal, no error shall result if standard error cannot be opened for reading.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of more:
COLUMNS Override the system-selected horizontal display line size. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.

EDITOR Used by the $\mathbf{v}$ command to select an editor. See the EXTENDED DESCRIPTION section.

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within regular expressions.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
LINES Override the system-selected vertical screen size, used as the number of lines in a screenful. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null. The $-\mathbf{n}$ option shall take precedence over the LINES variable for determining the number of lines in a screenful.

MORE Determine a string containing options described in the OPTIONS section preceded with hyphens and <blank>-separated as on the command line. Any command line49ael8 r the bR E9

TERM Determine the name of the terminal type. If this variable is unset or null, an unspecified default terminal type is used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be used to write the contents of the input files.

## STDERR

The standard error shall be used for diagnostic messages and user commands (see the INPUT FILES section), and, if standard output is a terminal device, to write a prompting string. The prompting string shall appear on the screen line below the last line of the file displayed in the current screenful. The prompt shall contain the name of the file currently being examined and shall contain an end-of-file indication and the name of the next file, if any, when prompting at the end-of-file. If an error or informational message is displayed, it is unspecified whether it is contained in the prompt. If it is not contained in the prompt, it shall be displayed and then the user shall be prompted for a continuation character, at which point another message or the user prompt may be displayed. The prompt is otherwise unspecified. It is unspecified whether informational messages are written for other user commands.

## OUTPUT FILES

 None.
## EXTENDED DESCRIPTION

The following section describes the behavior of more when the standard output is a terminal device. If the standard output is not a terminal device, no options other than -s shall have any effect, and all input files shall be copied to standard output otherwise unmodified, at which time more shall exit without further action.

The number of lines available per screen shall be determined by the -n option, if present, or by examining values in the environment (see the ENVIRONMENT VARIABLES section). If neither method yields a number, an unspecified number of lines shall be used.
The maximum number of lines written shall be one less than this number, because the screen line after the last line written shall be used to write a user prompt and user input. If the number of lines in the screen is less than two, the results are undefined. It is unspecified whether user input is permitted to be longer than the remainder of the single line where the prompt has been written.

The number of columns available per line shall be determined by examining values in the environment (see the ENVIRONMENT VARIABLES section), with a default value as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.
Lines that are longer than the display shall be folded; the length at which folding occurs is unspecified, but should be appropriate for the output device. Folding may occur between glyphs of single characters that take up multiple display columns.
When standard output is a terminal and $-\mathbf{u}$ is not specified, more shall treat <backspace>s and <carriage-return>s specially:

- A character, followed first by a sequence of $n<$ backspace>s (where $n$ is the same as the number of column positions that the character occupies), then by $n$ underscore characters ( ${ }^{\prime} \quad$ '), shall cause that character to be written as underlined text, if the terminal type supports that. The $n$ underscore characters, followed first by $n<$ backspace>s, then any character with $n$ column positions, shall also cause that character to be written as underlined text, if the terminal type supports that.
- A sequence of $n<$ backspace $>s$ (where $n$ is the same as the number of column positions that the previous character occupies) that appears between two identical printable characters shall cause the first of those two characters to be written as emboldened text (that is, visually brighter, standout mode, or inverse-video mode), if the terminal type supports that, and the second to be discarded. Immediately subsequent occurrences of <backspace>/character pairs for that same character shall also be discarded. (For example, the sequence " $\mathrm{a} \backslash \mathrm{ba} \backslash \mathrm{ba} \backslash \mathrm{ba}$ " is interpreted as a single emboldened ' $\mathrm{a}^{\prime}$. .)
- The more utility shall logically discard all other <backspace>s from the line as well as the character which precedes them, if any.
- A <carriage-return> at the end of a line shall be ignored, rather than being written as a non-printable character, as described in the next paragraph.
It is implementation-defined how other non-printable characters are written. Implementations should use the same format that they use for the ex print command; see the OPTIONS section within the ed utility. It is unspecified whether a multi-column character shall be separated if it crosses a display line boundary; it shall not be discarded. The behavior is unspecified if the number of columns on the display is less than the number of columns any single character in the line being displayed would occupy.
When each new file is displayed (or redisplayed), more shall write the first screen of the file. Once the initial screen has been written, more shall prompt for a user command. If the execution of the user command results in a screen that has lines in common with the current screen, and the device has sufficient terminal capabilities, more shall scroll the screen; otherwise, it is unspecified whether the screen is scrolled or redrawn.
For all files but the last (including standard input if no file was specified, and for the last file as well, if the -e option was not specified), when more has written the last line in the file, more shall prompt for a user command. This prompt shall contain the name of the next file as well as an indication that more has reached end-of-file. If the user command is $\mathbf{f},<$ control $>-\mathrm{F},<$ space $>, \mathbf{j}$, <newline>, d, <control>-D, or s, more shall display the next file. Otherwise, if displaying the last file, more shall exit. Otherwise, more shall execute the user command specified.
Several of the commands described in this section display a previous screen from the input stream. In the case that text is being taken from a non-rewindable stream, such as a pipe, it is implementation-defined how much backwards motion is supported. If a command cannot be executed because of a limitation on backwards motion, an error message to this effect shall be displayed, the current screen shall not change, and the user shall be prompted for another command.
If a command cannot be performed because there are insufficient lines to display, more shall alert the terminal. If a command cannot be performed because there are insufficient lines to display or a / command fails: if the input is the standard input, the last screen in the file may be displayed; otherwise, the current file and screen shall not change, and the user shall be prompted for another command.

The interactive commands in the following sections shall be supported. Some commands can be preceded by a decimal integer, called count in the following descriptions. If not specified with the command, count shall default to 1 . In the following descriptions, pattern is a basic regular expression, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions. The term "examine" is historical usage meaning "open the file for viewing"; for example, more foo would be expressed as examining file foo.
In the following descriptions, unless otherwise specified, line is a line in the more display, not a line from the file being examined.
In the following descriptions, the current position refers to two things:

1. The position of the current line on the screen
2. The line number (in the file) of the current line on the screen

Usually, the line on the screen corresponding to the current position is the third line on the screen. If this is not possible (there are fewer than three lines to display or this is the first page of the file, or it is the last page of the file), then the current position is either the first or last line on the screen as described later.

## Help

Synopsis: h
Write a summary of these commands and other implementation-defined commands. The behavior shall be as if the more utility were executed with the -e option on a file that contained the summary information. The user shall be prompted as described earlier in this section when end-of-file is reached. If the user command is one of those specified to continue to the next file, more shall return to the file and screen state from which the $\mathbf{h}$ command was executed.

## Scroll Forward One Screenful

Synopsis: [count]f
[count] <control>-F
Scroll forward count lines, with a default of one screenful. If count is more than the screen size, only the final screenful shall be written.

## Scroll Backward One Screenful <br> Synopsis: [count]b [count] <control>-B

Scroll backward count lines, with a default of one screenful (see the - $\mathbf{n}$ option). If count is more than the screen size, only the final screenful shall be written.

## Scroll Forward One Line

Synopsis: [count]<space>
[count] j
[count] <newline>
Scroll forward count lines. The default count for the <space> shall be one screenful; for $\mathbf{j}$ and <newline>, one line. The entire count lines shall be written, even if count is more than the screen size.

Scroll Backward One Line
Synopsis: [count]k
Scroll backward count lines. The entire count lines shall be written, even if count is more than the screen size.

## more

## Scroll Forward One Half Screenful

Synopsis: [count]d
[count]<control>-D
Scroll forward count lines, with a default of one half of the screen size. If count is specified, it shall become the new default for subsequent $\mathbf{d}$, <control>-D, and $\mathbf{u}$ commands.

## Skip Forward One Line

Synopsis: [count]s
Display the screenful beginning with the line count lines after the last line on the current screen. If count would cause the current position to be such that less than one screenful would be written, the last screenful in the file shall be written.

## Scroll Backward One Half Screenful

Synopsis: [count]u
[count]<control>-U
Scroll backward count lines, with a default of one half of the screen size. If count is specified, it shall become the new default for subsequent $\mathbf{d},<c o n t r o l>-D, \mathbf{u}$, and <control>-U commands. The entire count lines shall be written, even if count is more than the screen size.

## Go to Beginning of File

Synopsis: [count]g
Display the screenful beginning with line count.

If count is specified, display the screenful beginning with the line count. Otherwise, display the last screenful of the file.

## Refresh the Screen

Synopsis: $r$
<control>-L
Refresh the screen.
Discard and Refresh
Synopsis: $\quad \mathrm{R}$
Refresh the screen, discarding any buffered input. If the current file is non-seekable, buffered input shall not be discarded and the $\mathbf{R}$ command shall be equivalent to the $\mathbf{r}$ command.

## Mark Position

Synopsis: mletter
Mark the current position with the letter named by letter, where letter represents the name of one of the lowercase letters of the portable character set. When a new file is examined, all marks may be lost.

## Return to Mark

Synopsis: 'letter
Return to the position that was previously marked with the letter named by letter, making that line the current position.

## Return to Previous Position

Synopsis: ',
Return to the position from which the last large movement command was executed (where a "large movement" is defined as any movement of more than a screenful of lines). If no such movements have been made, return to the beginning of the file.

## Search Forward for Pattern

Synopsis: [count]/[!]pattern<newline>
Display the screenful beginning with the countth line containing the pattern. The search shall start after the first line currently displayed. The null regular expression ( ${ }^{\prime} /{ }^{\prime}$ followed by a <newline>) shall repeat the search using the previous regular expression, with a default count. If the character '!' is included, the matching lines shall be those that do not contain the pattern. If no match is found for the pattern, a message to that effect shall be displayed.

## Search Backward for Pattern <br> Synopsis: [count]?[!]páttern<newline>

Display the screenful beginning with the countth previous line containing the pattern. The search shall start on the last line before the first line currently displayed. The null regular expression (' ?' followed by a <newline>) shall repeat the search using the previous regular expression, with a default count. If the character ' $’$ is included, matching lines shall be those that do not contain the pattern. If no match is found for the pattern, a message to that effect shall be displayed.

## Repeat Search

Synopsis: [count]n
Repeat the previous search for countth line containing the last pattern (or not containing the last pattern, if the previous search was " $\langle$ !" or "? ! ").

Repeat Search in Reverse
Synopsis: [count] N
Repeat the search in the opposite direction of the previous search for the countth line containing the last pattern (or not containing the last pattern, if the previous search was "/!" or "?!").

## Examine New File

Synopsis: :e [filename]<newline>
Examine a new file. If the filename argument is not specified, the current file (see the :n and :p commands below) shall be re-examined. The filename shall be subjected to the process of shell word expansions (see Section 2.6 (on page 37)); if more than a single pathname results, the effects are unspecified. If filename is a number sign ( ${ }^{\prime} \#^{\prime}$ ), the previously examined file shall be re-examined. If filename is not accessible for any reason (including that it is a non-seekable file), an error message to this effect shall be displayed and the current file and screen shall not change.

## Examine Next File

Synopsis: [count]:n
Examine the next file. If a number count is specified, the countth next file shall be examined. If filename refers to a non-seekable file, the results are unspecified.

## Examine Previous File

Synopsis: [count]:p
Examine the previous file. If a number count is specified, the countth previous file shall be examined. If filename refers to a non-seekable file, the results are unspecified.

## Go to Tag

Synopsis: :t tagstring<newline>
If the file containing the tag named by the tagstring argument is not the current file, examine the file, as if the :e command was executed with that file as the argument. Otherwise, or in addition, display the screenful beginning with the tag, as described for the $-\mathbf{t}$ option (see the OPTIONS section). If the ctags utility is not supported by the system, the use of $: \mathbf{t}$ produces undefined results.

## Invoke Editor

Synopsis: V
Invoke an editor to edit the current file being examined. If standard input is being examined, the results are unspecified. The name of the editor shall be taken from the environment variable EDITOR, or shall default to $v i$. If the last pathname component in $E D I T O R$ is either $v i$ or $e x$, the editor shall be invoked with a-c linenumber command line argument, where linenumber is the line number of the file line containing the display line currently displayed as the first line of the screen. It is implementation-defined whether line-setting options are passed to editors other than $v i$ and $e x$.

When the editor exits, more shall resume with the same file and screen as when the editor was invoked.

```
Display Position
Synopsis:
```

Write a message for which the information references the first byte of the line after the last line of the file on the screen. This message shall include the name of the file currently being examined, its number relative to the total number of files there are to examine, the line number in the file, the byte number and the total bytes in the file, and what percentage of the file precedes the current position. If more is reading from standard input, or the file is shorter than a single screen, the line number, the byte number, the total bytes, and the percentage need not be written.

## Quit

Synopsis: $\quad \mathrm{q}$
:q
ZZ
Exit more.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If an error is encountered accessing a file when using the :n command, more shall attempt to examine the next file in the argument list, but the final exit status shall be affected. If an error is encountered accessing a file via the :p command, more shall attempt to examine the previous file in the argument list, but the final exit status shall be affected. If an error is encountered accessing a file via the :e command, more shall remain in the current file and the final exit status shall not be affected.

## APPLICATION USAGE

When the standard output is not a terminal, only the -s filter-modification option is effective. This is based on historical practice. For example, a typical implementation of man pipes its output through more -s to squeeze excess white space for terminal users. When man is piped to $l p$, however, it is undesirable for this squeezing to happen.

## EXAMPLES

The $-\mathbf{p}$ allows arbitrary commands to be executed at the start of each file. Examples are:
more - p G file1 file2
Examine each file starting with its last screenful.
more -p 100 file1 file 2
Examine each file starting with line 100 in the current position (usually the third line, so line 98 would be the first line written).
more - p / 100 file1 file 2
Examine each file starting with the first line containing the string 11000 in the current position

## RATIONALE

The more utility, available in BSD and BSD-derived systems, was chosen as the prototype for the POSIX file display program since it is more widely available than either the public-domain program less or than $p g$, a pager provided in System V. The 4.4 BSD more is the model for the features selected; it is almost fully upwards-compatible from the 4.3 BSD version in wide use and has become more amenable for vi users. Several features originally derived from various file editors, found in both less and $p g$, have been added to this volume of IEEE Std 1003.1-200x as they have proved extremely popular with users.
There are inconsistencies between more and vi that result from historical practice. For example, the single-character commands $\mathbf{h}, \mathbf{f}, \mathbf{b}$, and <space> are screen movers in more, but cursor movers in vi. These inconsistencies were maintained because the cursor movements are not applicable to more and the powerful functionality achieved without the use of the control key justifies the differences.

The tags interface has been included in a program that is not a text editor because it promotes another degree of consistent operation with $v i$. It is conceivable that the paging environment of more would be superior for browsing source code files in some circumstances.

The operating mode referred to for block-mode terminals effectively adds a <newline> to each Synopsis line that currently has none. So, for example, $\mathbf{d}<$ newline $>$ would page one screenful. The mode could be triggered by a command line option, environment variable, or some other method. The details are not imposed by this volume of IEEE Std 1003.1-200x because there are so few systems known to support such terminals. Nevertheless, it was considered that all systems should be able to support more given the exception cited for this small community of terminals
because, in comparison to vi, the cursor movements are few and the command set relatively amenable to the optional <newline>s.
Some versions of more provide a shell escaping mechanism similar to the ex ! command. The standard developers did not consider that this was necessary in a paginator, particularly given the wide acceptance of multiple window terminals and job control features. (They chose to retain such features in the editors and mailx because the shell interaction also gives an opportunity to modify the editing buffer, which is not applicable to more.)

The $-\mathbf{p}$ (position) option replaces the + command because of the Utility Syntax Guidelines. The +command option is no longer specified by this standard but may be present in some implementations. In early proposals, it took a pattern argument, but historical less provided the more general facility of a command. It would have been desirable to use the same $-\mathbf{c}$ as $e x$ and $v i$, but the letter was already in use.

The text stating "from a non-rewindable stream ... implementations may limit the amount of backwards motion supported" would allow an implementation that permitted no backwards motion beyond text already on the screen. It was not possible to require a minimum amount of backwards motion that would be effective for all conceivable device types. The implementation should allow the user to back up as far as possible, within device and reasonable memory allocation constraints.

Historically, non-printable characters were displayed using the ARPA standard mappings, which are as follows:

1. Printable characters are left alone.
2. Control characters less than $\backslash 177$ are represented as followed by the character offset from the ' @' character in the ASCII map; for example, $\backslash 007$ is represented as ' $\mathrm{G}^{\prime}$.
3. $\backslash 177$ is represented as followed by ' ?'.

The display of characters having their eighth bit set was less standard. Existing implementations use hex ( $0 x 00$ ), octal $(\backslash 000$ ), and a meta-bit display. (The latter displayed characters with their eighth bit set as the two characters $\mathrm{M} M-\mathrm{"}$, followed by the seven-bit display as described previously.) The latter probably has the best claim to historical practice because it was used with the -v option of 4 BSD and 4 BSD-derived versions of the cat utility since 1980.

No specific display format is required by IEEE Std 1003.1-200x. Implementations are encouraged to conform to historic practice in the absence of any strong reason to diverge.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 4.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The obsolescent SYNOPSIS is removed.
The utility has been extensively reworked for alignment with the IEEE P1003.2b draft standard:

- Changes have been made as a result of IEEE PASC Interpretations 1003.2 \#37 and \#109.
- The more utility should be able to handle underlined and emboldened displays of characters that are wider than a single column position.
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying that ${ }^{\prime}+^{\prime}$ may be recognized as an option delimiter in the OPTIONS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

mv - move files

## SYNOPSIS

> mv [-if] source_file target_file
> mv [-if] source_file... target_dir

## DESCRIPTION

In the first synopsis form, the $m v$ utility shall move the file named by the source_file operand to the destination specified by the target_file. This first synopsis form is assumed when the final operand does not name an existing directory and is not a symbolic link referring to an existing directory.
In the second synopsis form, $m v$ shall move each file named by a source file operand to a destination file in the existing directory named by the target_dir operand, or referenced if target_dir is a symbolic link referring to an existing directory. The destination path for each source_file shall be the concatenation of the target directory, a single slash character, and the last pathname component of the source_file. This second form is assumed when the final operand names an existing directory.
If any operand specifies an existing file of a type not specified by the System Interfaces volume of IEEE Std 1003.1-200x, the behavior is implementation-defined.
For each source_file the following steps shall be taken:

1. If the destination path exists, the $-\mathbf{f}$ option is not specified, and either of the following conditions is true:
a. The permissions of the destination path do not permit writing and the standard input is a terminal.
b. The -i option is specified.
the $m v$ utility shall write a prompt to standard error and read a line from standard input. If the response is not affirmative, $m 0$ shall do nothing more with the current source_file and go on to any remaining source_files.
2. The mv utility shall perform actions equivalent to the rename() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:
a. The source file operand is used as the old argument.
b. The destination path is used as the new argument.

If this succeeds, $m v$ shall do nothing more with the current source_file and go on to any remaining source_files. If this fails for any reasons other than those described for the errno [EXDEV] in the System Interfaces volume of IEEE Std 1003.1-200x, mv shall write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source_files.
3. If the destination path exists, and it is a file of type directory and source_file is not a file of type directory, or it is a file not of type directory and source_file is a file of type directory, $m v$ shall write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source_files.
4. If the destination path exists, $m v$ shall attempt to remove it. If this fails for any reason, $m v$ shall write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source_files.
5. The file hierarchy rooted in source_file shall be duplicated as a file hierarchy rooted in the destination path. If source file or any of the files below it in the hierarchy are symbolic links, the links themselves shall be duplicated, including their contents, rather than any files to which they refer. The following characteristics of each file in the file hierarchy shall be duplicated:

- The time of last data modification and time of last access
- The user ID and group ID
- The file mode

If the user ID, group ID, or file mode of a regular file cannot be duplicated, the file mode bits S_ISUID and S_ISGID shall not be duplicated.
When files are duplicated to another file system, the implementation may require that the process invoking $m v$ has read access to each file being duplicated.
If files being duplicated to another file system have hard links to other files, it is unspecified whether the files copied to the new file system have the hard links preserved or separate copies are created for the linked files.

If the duplication of the file hierarchy fails for any reason, $m v$ shall write a diagnostic message to standard error, do nothing more with the current source_file, and go on to any remaining source_files.
If the duplication of the file characteristics fails for any reason, $m v$ shall write a diagnostic message to standard error, but this failure shall not cause mo to modify its exit status.
6. The file hierarchy rooted in source file shall be removed. If this fails for any reason, mv shall write a diagnostic message to the standard error, do nothing more with the current source_file, and go on to any remaining source files.

## OPTIONS

The mv utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

> -f Do not prompt for confirmation if the destination path exists. Any previous occurrence of the -i option is ignored.
> Prompt for confirmation if the destination path exists. Any previous occurrence of the $-\mathbf{f}$ option is ignored.

Specifying more than one of the $-\mathbf{f}$ or $-\mathbf{i}$ options shall not be considered an error. The last option specified shall determine the behavior of $m v$.

## OPERANDS

The following operands shall be supported:
source_file A pathname of a file or directory to be moved.
target_file A new pathname for the file or directory being moved.
target_dir A pathname of an existing directory into which to move the input files.

## STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDERR section. Otherwise, the standard input shall not be used.

## INPUT FILES

The input files specified by each source_file operand can be of any file type.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $m v$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

Prompts shall be written to the standard error under the conditions specified in the DESCRIPTION section. The prompts shall contain the destination pathname, but their format is otherwise unspecified. Otherwise, the standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The output files may be of any file type.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were moved successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If the copying or removal of source_file is prematurely terminated by a signal or error, mv may leave a partial copy of source_file at the source or destination. The mv utility shall not modify both source file and the destination path simultaneously; termination at any point shall leave either source_file or the destination path complete.

## APPLICATION USAGE

Some implementations mark for update the st_ctime field of renamed files and some do not. Applications which make use of the st_ctime field may behave differently with respect to renamed files unless they are designed to allow for either behavior.

## EXAMPLES

If the current directory contains only files a (of any type defined by the System Interfaces volume of IEEE Std 1003.1-200x), $\mathbf{b}$ (also of any type), and a directory $\mathbf{c}$ :

```
mv a b c
mv c d
results with the original files \(\mathbf{a}\) and \(\mathbf{b}\) residing in the directory \(\mathbf{d}\) in the current directory.
```

## RATIONALE

Early proposals diverged from the SVID and BSD historical practice in that they required that when the destination path exists, the $-\mathbf{f}$ option is not specified, and input is not a terminal, mv fails. This was done for compatibility with $c p$. The current text returns to historical practice. It should be noted that this is consistent with the rename() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, which does not require write permission on the target.

For absolute clarity, paragraph (1), describing the behavior of $m v$ when prompting for confirmation, should be interpreted in the following manner:

```
if (exists AND (NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The -i option exists on BSD systems, giving applications and users a way to avoid accidentally unlinking files when moving others. When the standard input is not a terminal, the 4.3 BSD mv deletes all existing destination paths without prompting, even when -i is specified; this is inconsistent with the behavior of the 4.3 BSD $c p$ utility, which always generates an error when the file is unwritable and the standard input is not a terminal. The standard developers decided that use of $-\mathbf{i}$ is a request for interaction, so when the destination path exists, the utility takes instructions from whatever responds to standard input.
The rename () function is able to move directories within the same file system. Some historical versions of $m v$ have been able to move directories, but not to a different file system. The standard developers considered that this was an annoying inconsistency, so this volume of IEEE Std 1003.1-200x requires directories to be able to be moved even across file systems. There is no $-\mathbf{R}$ option to confirm that moving a directory is actually intended, since such an option was not required for moving directories in historical practice. Requiring the application to specify it sometimes, depending on the destination, seemed just as inconsistent. The semantics of the rename() function were preserved as much as possible. For example, $m v$ is not permitted to "rename" files to or from directories, even though they might be empty and removable.
Historic implementations of $m v$ did not exit with a non-zero exit status if they were unable to duplicate any file characteristics when moving a file across file systems, nor did they write a diagnostic message for the user. The former behavior has been preserved to prevent scripts from breaking; a diagnostic message is now required, however, so that users are alerted that the file characteristics have changed.
The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive prompts than those used on historical implementations. Therefore, an application not using the $-\mathbf{f}$ option or using the -i option relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.
When $m v$ is dealing with a single file system and source_file is a symbolic link, the link itself is moved as a consequence of the dependence on the rename() functionality, per the

DESCRIPTION. Across file systems, this has to be made explicit.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The mv utility is changed to describe processing of symbolic links as specified in the IEEE P1003.2b draft standard.
The APPLICATION USAGE section is added.

## Issue 7

SD5-XCU-ERN-13 is applied, making an editorial correction to the SYNOPSIS.
SD5-XCU-ERN-51 is applied to the DESCRIPTION, defining the behavior for when files are being duplicated to another file system while having hard links.

NAME
newgrp - change to a new group

## SYNOPSIS

newgrp [-l] [group]

## DESCRIPTION

 unspecified. change the effective group ID. it. there is room. database entries.If the first argument is ${ }^{\prime}-{ }^{\prime}$, the results are unspecified. suppress the changing of the group identification.

The newgrp utility shall create a new shell execution environment with a new real and effective group identification. Of the attributes listed in Section 2.12 (on page 61), the new shell execution environment shall retain the working directory, file creation mask, and exported variables from the previous environment (that is, open files, traps, unexported variables, alias definitions, shell functions, and set options may be lost). All other aspects of the process environment that are preserved by the exec family of functions defined in the System Interfaces volume of IEEE Std 1003.1-200x shall also be preserved by newgrp; whether other aspects are preserved is

A failure to assign the new group identifications (for example, for security or password-related reasons) shall not prevent the new shell execution environment from being created.

The newgrp utility shall affect the supplemental groups for the process as follows:

- On systems where the effective group ID is normally in the supplementary group list (or whenever the old effective group ID actually is in the supplementary group list):
- If the new effective group ID is also in the supplementary group list, newgrp shall
- If the new effective group ID is not in the supplementary group list, newgrp shall add the new effective group ID to the list, if there is room to add it.
- On systems where the effective group ID is not normally in the supplementary group list (or whenever the old effective group ID is not in the supplementary group list):
- If the new effective group ID is in the supplementary group list, newgrp shall delete
- If the old effective group ID is not in the supplementary list, newgrp shall add it if

Note: The System Interfaces volume of IEEE Std 1003.1-200x does not specify whether the effective group ID of a process is included in its supplementary group list.

With no operands, newgrp shall change the effective group back to the groups identified in the user's user entry, and shall set the list of supplementary groups to that set in the user's group

If a password is required for the specified group, and the user is not listed as a member of that group in the group database, the user shall be prompted to enter the correct password for that group. If the user is listed as a member of that group, no password shall be requested. If no password is required for the specified group, it is implementation-defined whether users not listed as members of that group can change to that group. Whether or not a password is required, implementation-defined system accounting or security mechanisms may impose additional authorization restrictions that may cause newgrp to write a diagnostic message and

OPTIONS
The newgrp utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for the unspecified usage of ${ }^{\prime} \mathbf{- '}^{\prime}$.

The following option shall be supported:
-1 (The letter ell.) Change the environment to what would be expected if the user actually logged in again.

## OPERANDS

The following operand shall be supported:
group A group name from the group database or a non-negative numeric group ID. Specifies the group ID to which the real and effective group IDs shall be set. If group is a non-negative numeric string and exists in the group database as a group name (see getgrnam()), the numeric group ID associated with that group name shall be used as the group ID.

## STDIN

Not used.

## INPUT FILES

The file /dev/tty shall be used to read a single line of text for password checking, when one is required.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of newgrp:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used for diagnostic messages and a prompt string for a password, if one is required. Diagnostic messages may be written in cases where the exit status is not available. See the EXIT STATUS section.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## EXIT STATUS

If newgrp succeeds in creating a new shell execution environment, whether or not the group identification was changed successfully, the exit status shall be the exit status of the shell. Otherwise, the following exit value shall be returned:
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

The invoking shell may terminate.

## APPLICATION USAGE

There is no convenient way to enter a password into the group database. Use of group passwords is not encouraged, because by their very nature they encourage poor security practices. Group passwords may disappear in the future.
A common implementation of newgrp is that the current shell uses exec to overlay itself with newgrp, which in turn overlays itself with a new shell after changing group. On some implementations, however, this may not occur and newgrp may be invoked as a subprocess.
The newgrp command is intended only for use from an interactive terminal. It does not offer a useful interface for the support of applications.
The exit status of newgrp is generally inapplicable. If newgrp is used in a script, in most cases it successfully invokes a new shell and the rest of the original shell script is bypassed when the new shell exits. Used interactively, newgrp displays diagnostic messages to indicate problems. But usage such as:
newgrp foo
echo \$?
is not useful because the new shell might not have access to any status newgrp may have generated (and most historical systems do not provide this status). A zero status echoed here does not necessarily indicate that the user has changed to the new group successfully. Following newgrp with the id command provides a portable means of determining whether the group change was successful or not.

## EXAMPLES

None.

## RATIONALE

Most historical implementations use one of the exec functions to implement the behavior of newgrp. Errors detected before the exec leave the environment unchanged, while errors detected after the exec leave the user in a changed environment. While it would be useful to have newgrp issue a diagnostic message to tell the user that the environment changed, it would be inappropriate to require this change to some historical implementations.
The password mechanism is allowed in the group database, but how this would be implemented is not specified.
The newgrp utility was retained in this volume of IEEE Std 1003.1-200x, even given the existence of the multiple group permissions feature in the System Interfaces volume of IEEE Std 1003.1-200x, for several reasons. First, in some implementations, the group ownership of a newly created file is determined by the group of the directory in which the file is created, as allowed by the System Interfaces volume of IEEE Std 1003.1-200x; on other implementations, the group ownership of a newly created file is determined by the effective group ID. On implementations of the latter type, newgrp allows files to be created with a specific group ownership. Finally, many implementations use the real group ID in accounting, and on such systems, newgrp allows the accounting identity of the user to be changed.

## newgrp

## FUTURE DIRECTIONS

None.
SEE ALSO
Chapter 2 (on page 29), sh, the System Interfaces volume of IEEE Std 1003.1-200x, exec, getgrnam()

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The obsolescent SYNOPSIS is removed.
The text describing supplemental groups is no longer conditional on \{NGROUPS_MAX\} being greater than 1. This is because \{NGROUPS_MAX\} now has a minimum value of 8 . This is a FIPS requirement.

Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying the behavior if the first argument is ${ }^{\prime}-$ '.

The newgrp utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
nice - invoke a utility with an altered nice value

## SYNOPSIS

```
nice [-n increment] utility [argument...]
```

## DESCRIPTION

The nice utility shall invoke a utility, requesting that it be run with a different nice value (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.239, Nice Value). With no options, the executed utility shall be run with a nice value that is some implementation-defined quantity greater than or equal to the nice value of the current process. If the user lacks appropriate privileges to affect the nice value in the requested manner, the nice utility shall not affect the nice value; in this case, a warning message may be written to standard error, but this shall not prevent the invocation of utility or affect the exit status.

## OPTIONS

The nice utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option is supported:
-n increment A positive or negative decimal integer which shall have the same effect on the execution of the utility as if the utility had called the nice() function with the numeric value of the increment option-argument.

## OPERANDS

The following operands shall be supported:
utility The name of a utility that is to be invoked. If the utility operand names any of the special built-in utilities in Section 2.14 (on page 64), the results are undefined.
argument Any string to be supplied as an argument when invoking the utility named by the utility operand.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of nice:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI

| NLSPATH | Determine the location of message catalogs for the processing of LC_MESSAGES. |
| :--- | :--- |
| PATH | Determine the search path used to locate the utility to be invoked. See the Base <br> Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables. |

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

If utility is invoked, the exit status of nice shall be the exit status of utility; otherwise, the nice utility shall exit with one of the following values:

1-125 An error occurred in the nice utility.
126 The utility specified by utility was found but could not be invoked.
127 The utility specified by utility could not be found.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The only guaranteed portable uses of this utility are:
nice utility
Run utility with the default higher or equal nice value.
nice $-\mathbf{n}<$ positive integer> utility
Run utility with a higher nice value.
On some implementations they have no discernible effect on the invoked utility and on some others they are exactly equivalent.
Historical systems have frequently supported the <positive integer> up to 20 . Since there is no error penalty associated with guessing a number that is too high, users without access to the system conformance document (to see what limits are actually in place) could use the historical 1 to 20 range or attempt to use very large numbers if the job should be truly low priority.
The nice value of a process can be displayed using the command:
ps -o nice
The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

## EXAMPLES

None.

## RATIONALE

The 4.3 BSD version of nice does not check whether increment is a valid decimal integer. The command nice -x utility, for example, would be treated the same as the command nice - $\mathbf{- 1}$ utility. If the user does not have appropriate privileges, this results in a "permission denied" error. This is considered a bug.

When a user without appropriate privileges gives a negative increment, System V treats it like the command nice $\mathbf{- 0}$ utility, while 4.3 BSD writes a "permission denied" message and does not run the utility. The standard specifies the System $V$ behavior together with an optional BSD-style "permission denied" message.
The C shell has a built-in version of nice that has a different interface from the one described in this volume of IEEE Std 1003.1-200x.

The term "utility" is used, rather than "command", to highlight the fact that shell compound commands, pipelines, and so on, cannot be used. Special built-ins also cannot be used. However, "utility" includes user application programs and shell scripts, not just utilities defined in this volume of IEEE Std 1003.1-200x.

Historical implementations of nice provide a nice value range of 40 or 41 discrete steps, with the default nice value being the midpoint of that range. By default, they raise the nice value of the executed utility by 10 .
Some historical documentation states that the increment value must be within a fixed range. This is misleading; the valid increment values on any invocation are determined by the current process nice value, which is not always the default.
The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of IEEE Std 1003.1-200x make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the nicerelated features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of IEEE Std 1003.1-200x, and others may have no effect at all. Because of the use of "implementation-defined" in nice and renice, a wide range of implementation strategies are possible.
Earlier versions of this standard allowed a -increment option. This form is no longer specified by this standard but may be present in some implementations.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Chapter 2 (on page 29), renice, the System Interfaces volume of IEEE Std 1003.1-200x, nice()

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The obsolescent SYNOPSIS is removed.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/18 is applied, deleting a paragraph of RATIONALE that referred to text no longer in the standard.

## Issue 7

SD5-XCU-ERN-32 and SD5-XCU-ERN-33 are applied, updating the DESCRIPTION, APPLICATION USAGE, and RATIONALE sections.

Austin Group Interpretation 1003.1-2001 \#027 is applied.
The nice utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

## NAME

nl — line numbering filter

## SYNOPSIS

xsi nl [-p] [-b type] [-d delim] [-f type] [-h type] [-i incr] [-l num] [-n format] [-s sep] [-v startnum] [-w width] [file]

## DESCRIPTION

The $n l$ utility shall read lines from the named file or the standard input if no file is named and shall reproduce the lines to standard output. Lines shall be numbered on the left. Additional functionality may be provided in accordance with the command options in effect.
The $n l$ utility views the text it reads in terms of logical pages. Line numbering shall be reset at the start of each logical page. A logical page consists of a header, a body, and a footer section. Empty sections are valid. Different line numbering options are independently available for header, body, and footer (for example, no numbering of header and footer lines while numbering blank lines only in the body).
The starts of logical page sections shall be signaled by input lines containing nothing but the following delimiter characters:

| Line | Start of |
| :--- | :--- |
| $\backslash: \backslash: \backslash:$ | Header |
| $\backslash: \backslash:$ | Body |
| $\backslash:$ | Footer |

Unless otherwise specified, $n l$ shall assume the text being read is in a single logical page body.

## OPTIONS

The $n l$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines. Only one file can be named.
The following options shall be supported:
-b type Specify which logical page body lines shall be numbered. Recognized types and their meaning are:
a Number all lines.
t Number only non-empty lines.
$n \quad$ No line numbering.
pstring Number only lines that contain the basic regular expression specified in string.
The default type for logical page body shall be $\mathbf{t}$ (text lines numbered).
-d delim Specify the delimiter characters that indicate the start of a logical page section. These can be changed from the default characters " $\backslash:$ " to two user-specified characters. If only one character is entered, the second character shall remain the default character ${ }^{\prime}$ :'
-f type Specify the same as $\mathbf{b}$ type except for footer. The default for logical page footer shall be $\mathbf{n}$ (no lines numbered).
-h type Specify the same as $\mathbf{b}$ type except for header. The default type for logical page header shall be $\mathbf{n}$ (no lines numbered).

> -i incr Specify the increment value used to number logical page lines. The default shall be 1.
> $\mathbf{- 1}$ num Specify the number of blank lines to be considered as one. For example, $\mathbf{- 1} \mathbf{2}$ results in only the second adjacent blank line being numbered (if the appropriate $-\mathbf{h} \mathbf{a}$, -b a, or -f a option is set). The default shall be 1.
> -n format Specify the line numbering format. Recognized values are: ln, left justified, leading zeros suppressed; rn, right justified, leading zeros suppressed; rz, right justified, leading zeros kept. The default format shall be rn (right justified).
> -p Specify that numbering should not be restarted at logical page delimiters.
> -s sep Specify the characters used in separating the line number and the corresponding text line. The default sep shall be a <tab>.
> -v startnum Specify the initial value used to number logical page lines. The default shall be 1.
> $-\mathbf{w}$ width Specify the number of characters to be used for the line number. The default width shall be 6.

## OPERANDS

The following operand shall be supported:
file A pathname of a text file to be line-numbered.

## STDIN

The standard input is a text file that is used if no file operand is given.

## INPUT FILES

The input file named by the file operand is a text file.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $n l$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes within regular expressions, and for deciding which characters are in character class graph (for the $-\mathbf{b} \mathbf{t},-\mathbf{f} \mathbf{t}$, and $-\mathbf{h} \mathbf{t}$ options).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be a text file in the following format:
"\%s\%s\%s", <line number>, <separator>, <input line>
where <line number> is one of the following numeric formats:
$\% 6 \mathrm{~d} \quad$ When the $\mathbf{r n}$ format is used (the default; see $-\mathbf{n}$ ).
$\% 06 \mathrm{~d} \quad$ When the $\mathbf{r z}$ format is used.
\%-6d When the $\ln$ format is used.
<empty> When line numbers are suppressed for a portion of the page; the <separator> is also suppressed.
In the preceding list, the number 6 is the default width; the $-\mathbf{w}$ option can change this value.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

In using the -d delim option, care should be taken to escape characters that have special meaning to the command interpreter.

## EXAMPLES

The command:
nl -v 10 -i $10-\mathrm{d} \mid!+$ file1
numbers file1 starting at line number 10 with an increment of 10 . The logical page delimiter is $"!+"$. Note that the ' ! has to be escaped when using csh as a command interpreter because of its history substitution syntax. For ksh and sh the escape is not necessary, but does not do any harm.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

## SEE ALSO

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The option [ $-\mathbf{f}$ type] is added to the SYNOPSIS. The option descriptions are presented in alphabetic order. The description of $-\mathbf{b t}$ is changed to "Number only non-empty lines".

Issue 6
The obsolescent behavior allowing the options to be intermingled with the optional file operand is removed.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

nm - write the name list of an object file (DEVELOPMENT)

## SYNOPSIS

sD nm [-APv] [-g|-u] [-t format] file...
xSI nm [-APv] [-efox] [-g|-u] [-t format] file...

## DESCRIPTION

The $n m$ utility shall display symbolic information appearing in the object file, executable file, or object-file library named by file. If no symbolic information is available for a valid input file, the $n m$ utility shall report that fact, but not consider it an error condition.
XSI The default base used when numeric values are written is unspecified. On XSI-conformant systems, it shall be decimal.

## OPTIONS

The $n m$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-A Write the full pathname or library name of an object on each line.
xSI -e Write only external (global) and static symbol information.
xsi $\mathbf{- f}$ Produce full output. Write redundant symbols (.text, .data, and .bss), normally suppressed.
-g Write only external (global) symbol information.
xSI - $\quad$ Write numeric values in octal (equivalent to $-\mathbf{t} \mathbf{0}$ ).
-P Write information in a portable output format, as specified in the STDOUT section.
$-\mathbf{t}$ format Write each numeric value in the specified format. The format shall be dependent on the single character used as the format option-argument:
xs
d The offset is written in decimal (default).

- The offset is written in octal.
x The offset is written in hexadecimal.
$-\mathbf{u} \quad$ Write only undefined symbols.
-v Sort output by value instead of alphabetically.
XSI $\quad \mathbf{x} \quad$ Write numeric values in hexadecimal (equivalent to $-\mathbf{t} \mathbf{x}$ ).

## OPERANDS

The following operand shall be supported:
file A pathname of an object file, executable file, or object-file library.

## STDIN

See the INPUT FILES section.

## INPUT FILES

The input file shall be an object file, an object-file library whose format is the same as those produced by the ar utility for link editing, or an executable file. The $n m$ utility may accept additional implementation-defined object library formats for the input file.

## ENVIRONMENT VARIABLES

## The following environment variables shall affect the execution of nm :

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for character collation information for the symbol-name and symbol-value collation sequences.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If symbolic information is present in the input files, then for each file or for each member of an archive, the $n m$ utility shall write the following information to standard output. By default, the format is unspecified, but the output shall be sorted alphabetically by symbol name:

- Library or object name, if -A is specified
- Symbol name
- Symbol type, which shall either be one of the following single characters or an implementation-defined type represented by a single character:
A Global absolute symbol.
a Local absolute symbol.
B Global "bss" (that is, uninitialized data space) symbol.
b Local bss symbol.
D Global data symbol.
d Local data symbol.
T Global text symbol.
t Local text symbol.
U Undefined symbol.
- Value of the symbol
- The size associated with the symbol, if applicable

This information may be supplemented by additional information specific to the implementation.
If the $\mathbf{- P}$ option is specified, the previous information shall be displayed using the following
portable format. The three versions differ depending on whether $-\mathbf{t} \mathbf{d}, \mathbf{t} \mathbf{0}$, or $-\mathbf{t} \mathbf{x}$ was specified, respectively:

```
"%s%s %s %d %d\n", <library/object name>, <name>, <type>,
    <value>, <size>
"%S%s %s %o %o\n", <library/object name>, <name>, <type>,
    <value>, <size>
"%s%s %s %x %x\n", <library/object name>, <name>, <type>,
    <value>, <size>
```

where <library/object name> shall be formatted as follows:

- If -A is not specified, <library/object name> shall be an empty string.
- If -A is specified and the corresponding file operand does not name a library:
"\%s: ", <file>
- If - $\mathbf{A}$ is specified and the corresponding file operand names a library. In this case, <object file> shall name the object file in the library containing the symbol being described:

```
"%s[%s]: ", <file>, <object file>
```

If -A is not specified, then if more than one file operand is specified or if only one file operand is specified and it names a library, $n m$ shall write a line identifying the object containing the following symbols before the lines containing those symbols, in the form:

- If the corresponding file operand does not name a library:
"\%s: \n", <file>
- If the corresponding file operand names a library; in this case, <object file> shall be the name of the file in the library containing the following symbols:

```
"%s[%s]:\n", <file>, <object file>
```

If $-\mathbf{P}$ is specified, but $\mathbf{t}$ is not, the format shall be as if $-\mathbf{t} \mathbf{x}$ had been specified.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Mechanisms for dynamic linking make this utility less meaningful when applied to an executable file because a dynamically linked executable may omit numerous library routines that would be found in a statically linked executable.

## EXAMPLES

None.

## RATIONALE

Historical implementations of $n m$ have used different bases for numeric output and supplied different default types of symbols that were reported. The $-\mathbf{t}$ format option, similar to that used in od and strings, can be used to specify the numeric base; -g and -u can be used to restrict the amount of output or the types of symbols included in the output.
The compromise of using $-\mathbf{t}$ format versus using $-\mathbf{d},-\mathbf{o}$, and other similar options was necessary because of differences in the meaning of $-\mathbf{o}$ between implementations. The $-\mathbf{o}$ option from BSD has been provided here as $-\mathbf{A}$ to avoid confusion with the $-\mathbf{o}$ from System V (which has been provided here as $-\mathbf{t}$ and as $-\mathbf{o}$ on XSI-conformant systems).
The option list was significantly reduced from that provided by historical implementations.
The $n m$ description is a subset of both the System V and BSD nm utilities with no specified default output.
It was recognized that mechanisms for dynamic linking make this utility less meaningful when applied to an executable file (because a dynamically linked executable file may omit numerous library routines that would be found in a statically linked executable file), but the value of nm during software development was judged to outweigh other limitations.
The default output format of $n m$ is not specified because of differences in historical implementations. The $-\mathbf{P}$ option was added to allow some type of portable output format. After a comparison of the different formats used in SunOS, BSD, SVR3, and SVR4, it was decided to create one that did not match the current format of any of these four systems. The format devised is easy to parse by humans, easy to parse in shell scripts, and does not need to vary depending on locale (because no English descriptions are included). All of the systems currently have the information available to use this format.
The format given in $n m$ STDOUT uses spaces between the fields, which may be any number of <blank>s required to align the columns. The single-character types were selected to match historical practice, and the requirement that implementation additions also be single characters made parsing the information easier for shell scripts.

## FUTURE DIRECTIONS

None.

## SEE ALSO

ar, c99

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as supported when both the User Portability Utilities option and the Software Development Utilities option are supported.

## Issue 7

The $n m$ utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
nohup - invoke a utility immune to hangups

## SYNOPSIS

```
nohup utility [argument...]
```

## DESCRIPTION

The nohup utility shall invoke the utility named by the utility operand with arguments supplied as the argument operands. At the time the named utility is invoked, the SIGHUP signal shall be set to be ignored.
If standard input is associated with a terminal, the nohup utility may redirect standard input from an unspecified file.
If the standard output is a terminal, all output written by the named utility to its standard output shall be appended to the end of the file nohup.out in the current directory. If nohup.out cannot be created or opened for appending, the output shall be appended to the end of the file nohup.out in the directory specified by the HOME environment variable. If neither file can be created or opened for appending, utility shall not be invoked. If a file is created, the file's permission bits shall be set to S_IRUSR I S_IWUSR.
If standard error is a terminal and standard output is open but is not a terminal, all output written by the named utility to its standard error shall be redirected to the same open file description as the standard output. If standard error is a terminal and standard output either is a terminal or is closed, the same output shall instead be appended to the end of the nohup.out file as described above.

## OPTIONS

None.

## OPERANDS

The following operands shall be supported:
utility The name of a utility that is to be invoked. If the utility operand names any of the special built-in utilities in Section 2.14 (on page 64), the results are undefined.
argument Any string to be supplied as an argument when invoking the utility named by the utility operand.

## STDIN

Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of nohup:
HOME Determine the pathname of the user's home directory: if the output file nohup.out cannot be created in the current directory, the nohup utility shall use the directory named by HOME to create the file.

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the search path that is used to locate the utility to be invoked. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

## ASYNCHRONOUS EVENTS

The nohup utility shall take the standard action for all signals except that SIGHUP shall be ignored.

## STDOUT

If the standard output is not a terminal, the standard output of nohup shall be the standard output generated by the execution of the utility specified by the operands. Otherwise, nothing shall be written to the standard output.

## STDERR

If the standard output is a terminal, a message shall be written to the standard error, indicating the name of the file to which the output is being appended. The name of the file shall be either nohup.out or \$HOME/nohup.out.

## OUTPUT FILES

Output written by the named utility is appended to the file nohup.out (or \$HOME/nohup.out), if the conditions hold as described in the DESCRIPTION.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
126 The utility specified by utility was found but could not be invoked.
127 An error occurred in the nohup utility or the utility specified by utility could not be found.

Otherwise, the exit status of nohup shall be that of the utility specified by the utility operand.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

## EXAMPLES

It is frequently desirable to apply nohup to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the nohup applies to everything in the file.

Alternatively, the following command can be used to apply nohup to a complex command:
nohup sh -c 'complex-command-line' </dev/null

## RATIONALE

The 4.3 BSD version ignores SIGTERM and SIGHUP, and if ./nohup.out cannot be used, it fails instead of trying to use \$HOME/nohup.out.

The csh utility has a built-in version of nohup that acts differently from the nohup defined in this volume of IEEE Std 1003.1-200x.

The term utility is used, rather than command, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, utility includes user application programs and shell scripts, not just the standard utilities.

Historical versions of the nohup utility use default file creation semantics. Some more recent versions use the permissions specified here as an added security precaution.

Some historical implementations ignore SIGQUIT in addition to SIGHUP; others ignore SIGTERM. An early proposal allowed, but did not require, SIGQUIT to be ignored. Several reviewers objected that nohup should only modify the handling of SIGHUP as required by this volume of IEEE Std 1003.1-200x.

Historical versions of nohup did not affect standard input, but that causes problems in the common scenario where the user logs into a system, types the command:

```
nohup make &
```

at the prompt, and then logs out. If standard input is not affected by nohup, the login session may not terminate for quite some time, since standard input remains open until make exits. To avoid this problem, this standard allows implementations to redirect standard input if it is a terminal. Since the behavior is implementation-defined, portable applications that may run into the problem should redirect standard input themselves. For example, instead of:
nohup make \&
an application can invoke:
nohup make </dev/null \&

## FUTURE DIRECTIONS

## CHANGE HISTORY

First released in Issue 2.
Issue 7
Austin Group Interpretations 1003.1-2001 \#104, \#105, and \#106 are applied.

## NAME

od - dump files in various formats

## SYNOPSIS

```
od [-v] [-A address_base] [-j skip] [-N count] [-t type_string]...
        [file...]
    od [-bcdosx] [file] [[+]offset[.][b]]
```

## DESCRIPTION

The od utility shall write the contents of its input files to standard output in a user-specified format.

## OPTIONS

The od utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, xSI Utility Syntax Guidelines, except that the order of presentation of the $-\mathbf{t}$ options and the -bcdosx options is significant.

The following options shall be supported:
-A address_base
Specify the input offset base. See the EXTENDED DESCRIPTION section. The application shall ensure that the address_base option-argument is a character. The characters ' d ', ' 0 ', and ' x ' specify that the offset base shall be written in decimal, octal, or hexadecimal, respectively. The character ' $n$ ' specifies that the offset shall not be written.
xSI -b Interpret bytes in octal. This shall be equivalent to $-\mathbf{t} \mathbf{0 1}$.
xsi
-c Interpret bytes as characters specified by the current setting of the LC_CTYPE category. Certain non-graphic characters appear as C escapes: "NUL=\0", "BS $=\backslash \mathrm{b} "$, "FF=\£", "NL=\n", "CR=\r", "HT=\t"; others appear as 3-digit octal numbers.
XSI -d Interpret words (two-byte units) in unsigned decimal. This shall be equivalent to $-\mathbf{t} \mathbf{u}$.
-j skip Jump over skip bytes from the beginning of the input. The od utility shall read or seek past the first skip bytes in the concatenated input files. If the combined input is not at least skip bytes long, the od utility shall write a diagnostic message to standard error and exit with a non-zero exit status.
By default, the skip option-argument shall be interpreted as a decimal number. With a leading 0 x or 0 X , the offset shall be interpreted as a hexadecimal number; otherwise, with a leading ' 0 ', the offset shall be interpreted as an octal number. Appending the character ' $b^{\prime}$, ' $k^{\prime}$, or ' $m^{\prime}$ to offset shall cause it to be interpreted as a multiple of 512,1024 , or 1048576 bytes, respectively. If the skip number is hexadecimal, any appended ' b ' shall be considered to be the final hexadecimal digit.
-N count Format no more than count bytes of input. By default, count shall be interpreted as a decimal number. With a leading $0 x$ or $0 X$, count shall be interpreted as a hexadecimal number; otherwise, with a leading ' 0 ', it shall be interpreted as an octal number. If count bytes of input (after successfully skipping, if $-\mathbf{j}$ skip is specified) are not available, it shall not be considered an error; the od utility shall format the input that is available.

| 26718 | XSI | -0 | Interpret words (two-byte units) in octal. This shall be equivalent to -t $\mathbf{0} \mathbf{2}$. |
| :---: | :---: | :---: | :---: |
| 26719 | XSI | -s | Interpret words (two-byte units) in signed decimal. This shall be equivalent to |
| 26720 |  |  | -t d2. |
| 26721 |  | -t type_string |  |
| 26722 |  |  | Specify one or more output types. See the EXTENDED DESCRIPTION section. The application shall ensure that the type_string option-argument is a string specifying |
| 26723 |  |  |  |
| 26724 |  |  | the types to be used when writing the input data. The string shall consist of the |
| 26725 |  |  | type specification characters $a, c, d, f, 0, u$, and $x$, specifying named character, |
| 26726 |  |  | character, signed decimal, floating point, octal, unsigned decimal, and |
| 26727 |  |  | hexadecimal, respectively. The type specification characters $d, f, 0, u$, and $x$ can be |
| 26728 |  |  | followed by an optional unsigned decimal integer that specifies the number of |
| 26729 |  |  | bytes to be transformed by each instance of the output type. The type specification |
| 26730 |  |  | character f can be followed by an optional F, D, or L indicating that the conversion |
| 26731 |  |  | should be applied to an item of type float, double, or long double, respectively. |
| 26732 |  |  | The type specification characters $d, o, u$, and $x$ can be followed by an optional $C, S$, |
| 26733 |  |  | I, or L indicating that the conversion should be applied to an item of type char, short, int, or long, respectively. Multiple types can be concatenated within the |
| 26734 |  |  |  |
| 26735 |  |  | same type_string and multiple -t options can be specified. Output lines shall be |
| 26736 |  |  | written for each type specified in the order in which the type specification |
| 26737 |  |  |  |
| 26738 |  | -v | Write all input data. Without the -v option, any number of groups of output lines, |
| 26739 |  |  | which would be identical to the immediately preceding group of output lines |
| 26740 |  |  | (except for the byte offsets), shall be replaced with a line containing only anasterisk ( $\times^{\prime \prime}$ ). |
| 26741 |  |  |  |
| 26742 | XSI | -x | Interpret words (two-byte units) in hexadecimal. This shall be equivalent to -t x2 . |
| 26743 26744 | XSI | Multiple types can be specified by using multiple -bcdostx options. Output lines are written for each type specified in the order in which the types are specified. |  |

## OPERANDS

The following operands shall be supported:
file A pathname of a file to be read. If no file operands are specified, the standard input shall be used.

If there are no more than two operands, none of the $-\mathbf{A},-\mathbf{j},-\mathbf{N},-\mathbf{t}$, or $-\mathbf{v}$ options is specified, and either of the following is true: the first character of the last operand is a plus sign $\left({ }^{\prime}+{ }^{\prime}\right)$, or there are two operands and the first character of the last operand is numeric; the last operand shall be interpreted as an offset operand on XSI-conformant systems. Under these conditions, the results are unspecified on systems that are not XSI-conformant systems.
xsi [+]offset[.][b] The offset operand specifies the offset in the file where dumping is to commence. This operand is normally interpreted as octal bytes. If ' .' is appended, the offset shall be interpreted in decimal. If ' $b$ ' is appended, the offset shall be interpreted in units of 512 bytes.

STDIN
The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

The input files can be any file type.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of od:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_NUMERIC
Determine the locale for selecting the radix character used when writing floatingpoint formatted output.
xSi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

See the EXTENDED DESCRIPTION section.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

The od utility shall copy sequentially each input file to standard output, transforming the input data according to the output types specified by the $-\mathbf{t}$ option or the $-\mathbf{b c d o s x}$ options. If no output type is specified, the default output shall be as if $-\mathbf{t} \mathbf{o S}$ had been specified.

The number of bytes transformed by the output type specifier c may be variable depending on the LC_CTYPE category.
The default number of bytes transformed by output type specifiers $d, f, 0, u$, and $x$ corresponds to the various C-language types as follows. If the c99 compiler is present on the system, these specifiers shall correspond to the sizes used by default in that compiler. Otherwise, these sizes may vary among systems that conform to IEEE Std 1003.1-200x.

- For the type specifier characters $d, 0, u$, and $x$, the default number of bytes shall correspond to the size of the underlying implementation's basic integer type. For these specifier characters, the implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types char, short, int, and long. These numbers can also be specified by an application as the characters ' $C^{\prime}, ~ ' S ', ~ ' I '$, and ' $L^{\prime}$, respectively. The implementation shall also support the values $1,2,4$, and 8 , even if it provides no C-Language types of those sizes. The implementation shall support the decimal value corresponding to the C-language type long long. The byte order used when interpreting numeric values is implementationdefined, but shall correspond to the order in which a constant of the corresponding type is stored in memory on the system.
- For the type specifier character $f$, the default number of bytes shall correspond to the number of bytes in the underlying implementation's basic double precision floating-point data type. The implementation shall support values of the optional number of bytes to be converted corresponding to the number of bytes in the C-language types float, double, and long double. These numbers can also be specified by an application as the characters ' $\mathrm{F}^{\prime},{ }^{\prime} \mathrm{D}^{\prime}$, and ' $\mathrm{L}^{\prime}$, respectively.

The type specifier character a specifies that bytes shall be interpreted as named characters from the International Reference Version (IRV) of the ISO/IEC 646:1991 standard. Only the least significant seven bits of each byte shall be used for this type specification. Bytes with the values listed in the following table shall be written using the corresponding names for those characters.

Table 4-12 Named Characters in od

| Value | Name | Value | Name | Value | Name | Value | Name |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\backslash 000$ | nul | $\backslash 001$ | soh | $\backslash 002$ | stx | $\backslash 003$ | etx |
| $\backslash 004$ | eot | $\backslash 005$ | enq | $\backslash 006$ | ack | $\backslash 007$ | bel |
| $\backslash 010$ | bs | $\backslash 011$ | ht | $\backslash 012$ | lf or nl | $\backslash 013$ | vt |
| $\backslash 014$ | ff | $\backslash 015$ | cr | $\backslash 016$ | so | $\backslash 017$ | si |
| $\backslash 020$ | dle | $\backslash 021$ | dc1 | $\backslash 022$ | dc2 | $\backslash 023$ | dc3 |
| $\backslash 024$ | dc4 | $\backslash 025$ | nak | $\backslash 026$ | syn | $\backslash 027$ | etb |
| $\backslash 030$ | can | $\backslash 031$ | em | $\backslash 032$ | sub | $\backslash 033$ | esc |
| $\backslash 034$ | fs | $\backslash 035$ | gs | $\backslash 036$ | rs | $\backslash 037$ | us |
| $\backslash 040$ | sp | $\backslash 177$ | del |  |  |  |  |

Note: The " $\backslash 012$ " value may be written either as lf or $\mathbf{n l}$.
The type specifier character c specifies that bytes shall be interpreted as characters specified by the current setting of the LC_CTYPE locale category. Characters listed in the table in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation ( $\backslash \backslash{ }^{\prime}, \quad$ ' $\backslash \mathrm{a}^{\prime}$, $\left.' \backslash \mathrm{~b}^{\prime}, ' \backslash \mathrm{f}^{\prime}, ' \backslash \mathrm{n}^{\prime}, ' \backslash \mathrm{r}^{\prime}, \backslash \mathrm{t}^{\prime}, \mathrm{g}^{\prime} \backslash \mathrm{v}^{\prime}\right)$ shall be written as the corresponding escape sequences, except that backslash shall be written as a single backslash and a NUL shall be written as ${ }^{\prime} \backslash 0^{\prime}$. Other non-printable characters shall be written as one three-digit octal number for each byte in the character. Printable multi-byte characters shall be written in the area corresponding to the first byte of the character; the two-character sequence "**" shall be written in the area corresponding to each remaining byte in the character, as an indication that the character is continued. When either the $-\mathbf{j}$ skip or $-\mathbf{N}$ count option is specified along with the c type specifier, and this results in an attempt to start or finish in the middle of a multi-byte character, the result is implementation-defined.

The input data shall be manipulated in blocks, where a block is defined as a multiple of the least common multiple of the number of bytes transformed by the specified output types. If the least common multiple is greater than 16, the results are unspecified. Each input block shall be written as transformed by each output type, one per written line, in the order that the output types were specified. If the input block size is larger than the number of bytes transformed by the output type, the output type shall sequentially transform the parts of the input block, and the output from each of the transformations shall be separated by one or more <blank>s.
If, as a result of the specification of the $-\mathbf{N}$ option or end-of-file being reached on the last input file, input data only partially satisfies an output type, the input shall be extended sufficiently with null bytes to write the last byte of the input.
Unless -A $\mathbf{n}$ is specified, the first output line produced for each input block shall be preceded by the input offset, cumulative across input files, of the next byte to be written. The format of the input offset is unspecified; however, it shall not contain any <blank>s, shall start at the first character of the output line, and shall be followed by one or more <blank>s. In addition, the offset of the byte following the last byte written shall be written after all the input data has been
processed, but shall not be followed by any <blank>s.
If no -A option is specified, the input offset base is unspecified.

## EXIT STATUS

The following exit values shall be returned:
0 All input files were processed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

XSI-conformant applications are warned not to use filenames starting with ' + ' or a first operand starting with a numeric character so that the old functionality can be maintained by implementations, unless they specify one of the $-\mathbf{A},-\mathbf{j}$, or $-\mathbf{N}$ options. To guarantee that one of these filenames is always interpreted as a filename, an application could always specify the address base format with the -A option.

## EXAMPLES

If a file containing 128 bytes with decimal values zero to 127 , in increasing order, is supplied as standard input to the command:

```
od -A d -t a
```

on an implementation using an input block size of 16 bytes, the standard output, independent of the current locale setting, would be similar to:

Note that this volume of IEEE Std 1003.1-200x allows nl or lf to be used as the name for the ISO/IEC 646:1991 standard IRV character with decimal value 10. The IRV names this character lf (line feed), but traditional implementations have referred to this character as newline (nl) and the POSIX locale character set symbolic name for the corresponding character is a <newline>.
The command:

```
od -A O -t o2x2x -N 18
```

on a system with 32 -bit words and an implementation using an input block size of 16 bytes could write 18 bytes in approximately the following format:

| 0000000 | 032056 | 031440 | 041123 | 042040 | 052516 | 044530 | 020043 |
| :---: | :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $342 e$ | 3320 | 4253 | 4420 | $554 e$ | 4958 | 2023 | 3334 |
| 3 | $342 e 3320$ | 42534420 | $554 e 4958$ | 20233334 |  |  |  |

The command:

```
od -A d -t f -t o4 -t x4 -N 24 -j 0x15
```

on a system with 64-bit doubles (for example, IEEE Std 754-1985 double precision floating-point format) would skip 21 bytes of input data and then write 24 bytes in approximately the following format:

```
0000000 1.00000000000000e+00 1.57350000000000e+01
    07774000000 00000000000 10013674121 35341217270
    3ff00000 00000000 402f3851 eb851eb8
0000016 1.40668230000000e+02
    10030312542 04370303230
    40619562 23e18698
0000024
```

## RATIONALE

The od utility went through several names in early proposals, including $h d, x d$, and most recently hexdump. There were several objections to all of these based on the following reasons:

- The $h d$ and $x d$ names conflicted with historical utilities that behaved differently.
- The hexdump description was much more complex than needed for a simple dump utility.
- The od utility has been available on all historical implementations and there was no need to create a new name for a utility so similar to the historical od utility.

The original reasons for not standardizing historical od were also fairly widespread. Those reasons are given below along with rationale explaining why the standard developers believe that this version does not suffer from the indicated problem:

- The BSD and System $V$ versions of od have diverged, and the intersection of features provided by both does not meet the needs of the user community. In fact, the System V version only provides a mechanism for dumping octal bytes and shorts, signed and unsigned decimal shorts, hexadecimal shorts, and ASCII characters. BSD added the ability to dump floats, doubles, named ASCII characters, and octal, signed decimal, unsigned decimal, and hexadecimal longs. The version presented here provides more normalized forms for dumping bytes, shorts, ints, and longs in octal, signed decimal, unsigned decimal, and hexadecimal; float, double, and long double; and named ASCII as well as current locale characters.
- It would not be possible to come up with a compatible superset of the BSD and System V flags that met the requirements of the standard developers. The historical default od output is the specified default output of this utility. None of the option letters chosen for this version of od conflict with any of the options to historical versions of od.
- On systems with different sizes for short, int, and long, there was no way to ask for dumps of ints, even in the BSD version. Because of the way options are named, the name space could not be extended to solve these problems. This is why the $-\mathbf{t}$ option was added (with type specifiers more closely matched to the printf() formats used in the rest of this volume of IEEE Std 1003.1-200x) and the optional field sizes were added to the $d, f, 0, u$, and $x$ type specifiers. It is also one of the reasons why the historical practice was not mandated as a required obsolescent form of od. (Although the old versions of od are not listed as an obsolescent form, implementations are urged to continue to recognize the older forms for several more years.) The $a, c, f, 0$, and $x$ types match the meaning of the corresponding format characters in the historical implementations of od except for the default sizes of the fields converted. The d format is signed in this volume of IEEE Std 1003.1-200x to match the $\operatorname{printf}()$ notation. (Historical versions of od used d as a synonym for $u$ in this version. The System V implementation uses s for signed decimal; BSD uses i for signed decimal and $s$ for null-terminated strings.) Other than $d$ and $u$, all of the type specifiers match format characters in the historical BSD version of od.
The sizes of the C-language types char, short, int, long, float, double, and long double are
used even though it is recognized that there may be zero or more than one compiler for the $C$ language on an implementation and that they may use different sizes for some of these types. (For example, one compiler might use 2 bytes shorts, 2 bytes ints, and 4 bytes longs, while another compiler (or an option to the same compiler) uses 2 bytes shorts, 4 bytes ints, and 4 bytes longs.) Nonetheless, there has to be a basic size known by the implementation for these types, corresponding to the values reported by invocations of the getconf utility when called with system_var operands \{UCHAR_MAX\}, \{USHORT_MAX\}, \{UINT_MAX\}, and \{ULONG_MAX\} for the types char, short, int, and long, respectively. There are similar constants required by the ISO C standard, but not required by the System Interfaces volume of IEEE Std 1003.1-200x or this volume of IEEE Std 1003.1-200x. They are \{FLT_MANT_DIG\}, \{DBL_MANT_DIG\}, and \{LDBL_MANT_DIG\} for the types float, double, and long double, respectively. If the optional c99 utility is provided by the implementation and used as specified by this volume of IEEE Std 1003.1-200x, these are the sizes that would be provided. If an option is used that specifies different sizes for these types, there is no guarantee that the od utility is able to interpret binary data output by such a program correctly.
This volume of IEEE Std 1003.1-200x requires that the numeric values of these lengths be recognized by the od utility and that symbolic forms also be recognized. Thus, a conforming application can always look at an array of unsigned long data elements using od $-\mathbf{t} u \mathrm{~L}$.
- The method of specifying the format for the address field based on specifying a starting offset in a file unnecessarily tied the two together. The - $\mathbf{A}$ option now specifies the address base and the - $\mathbf{S}$ option specifies a starting offset.
- It would be difficult to break the dependence on U.S. ASCII to achieve an internationalized utility. It does not seem to be any harder for od to dump characters in the current locale than it is for the ed or sed 1 commands. The c type specifier does this without difficulty and is completely compatible with the historical implementations of the $\mathbf{c}$ format character when the current locale uses a superset of the ISO/IEC 646: 1991 standard as a codeset. The a type specifier (from the BSD a format character) was left as a portable means to dump ASCII (or more correctly ISO/IEC 646:1991 standard (IRV)) so that headers produced by pax could be deciphered even on systems that do not use the ISO/IEC 646: 1991 standard as a subset of their base codeset.

The use of $" \star \star v$ as an indication of continuation of a multi-byte character in c specifier output was chosen based on seeing an implementation that uses this method. The continuation bytes have to be marked in a way that is not ambiguous with another single-byte or multi-byte character.

An early proposal used $-\mathbf{S}$ and $-\mathbf{n}$, respectively, for the $-\mathbf{j}$ and $-\mathbf{N}$ options eventually selected. These were changed to avoid conflicts with historical implementations.
The original standard specified $-\mathbf{t} \mathbf{o 2}$ as the default when no output type was given. This was changed to $\mathbf{- t} \mathbf{o S}$ (the length of a short) to accommodate a supercomputer implementation that historically used 64 bits as its default (and that defined shorts as 64 bits). This change should not affect conforming applications. The requirement to support lengths of 1,2 , and 4 was added at the same time to address an historical implementation that had no two-byte data types in its C compiler.
The use of a basic integer data type is intended to allow the implementation to choose a word size commonly used by applications on that architecture.

Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

## FUTURE DIRECTIONS

All option and operand interfaces marked as extensions may be withdrawn in a future version.

## CHANGE HISTORY

First released in Issue 2.
Issue 5
In the description of the $-\mathbf{c}$ option, the phrase "This is equivalent to $\mathbf{- t} \mathbf{c}$." is deleted.
The FUTURE DIRECTIONS section is modified.
Issue 6
The od utility is changed to remove the assumption that short was a two-byte entity, as per the revisions in the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/33 is applied, correcting the examples which used an undefined $-\mathbf{n}$ option, which should have been $-\mathbf{N}$.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/19 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.

Issue 7
SD5-XCU-ERN-37 is applied, updating the OPERANDS section.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
paste - merge corresponding or subsequent lines of files

## SYNOPSIS

paste [-s] [-d list] file...

## DESCRIPTION

The paste utility shall concatenate the corresponding lines of the given input files, and write the resulting lines to standard output.
The default operation of paste shall concatenate the corresponding lines of the input files. The <newline> of every line except the line from the last input file shall be replaced with a <tab>.
If an end-of-file condition is detected on one or more input files, but not all input files, paste shall behave as though empty lines were read from the files on which end-of-file was detected, unless the -s option is specified.

## OPTIONS

The paste utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-d list Unless a backslash character appears in list, each character in list is an element specifying a delimiter character. If a backslash character appears in list, the backslash character and one or more characters following it are an element specifying a delimiter character as described below. These elements specify one or more delimiters to use, instead of the default <tab>, to replace the <newline> of the input lines. The elements in list shall be used circularly; that is, when the list is exhausted the first element from the list is reused. When the -soption is specified:

- The last <newline> in a file shall not be modified.
- The delimiter shall be reset to the first element of list after each file operand is processed.
When the - s option is not specified:
- The <newline>s in the file specified by the last file operand shall not be modified.
- The delimiter shall be reset to the first element of list each time a line is processed from each file.
If a backslash character appears in list, it and the character following it shall be used to represent the following delimiter characters:
\n <newline>.
\t <tab>.
<br> Backslash character.
$\backslash 0$

Concatenate all of the lines of each separate input file in command line order. The <newline> of every line except the last line in each input file shall be replaced with the <tab>, unless otherwise specified by the -d option.

OPERANDS
The following operand shall be supported:
file A pathname of an input file. If '_' is specified for one or more of the files, the standard input shall be used; the standard input shall be read one line at a time, circularly, for each instance of ' - '. Implementations shall support pasting of at least 12 file operands.

## STDIN

The standard input shall be used only if one or more file operands is ' ${ }^{\prime}$ '. See the INPUT FILES section.

## INPUT FILES

The input files shall be text files, except that line lengths shall be unlimited.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of paste:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Concatenated lines of input files shall be separated by the <tab> (or other characters under the control of the -d option) and terminated by a <newline>.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If one or more input files cannot be opened when the -s option is not specified, a diagnostic message shall be written to standard error, but no output is written to standard output. If the -s option is specified, the paste utility shall provide the default behavior described in Section 1.11 (on page 18).

## APPLICATION USAGE

When the escape sequences of the list option-argument are used in a shell script, they must be quoted; otherwise, the shell treats the ' $\backslash$ ' as a special character.

Conforming applications should only use the specific backslash escaped delimiters presented in this volume of IEEE Std 1003.1-200x. Historical implementations treat ' $\backslash x$ ', where ' $x$ ' is not in this list, as ' $x$ ', but future implementations are free to expand this list to recognize other common escapes similar to those accepted by printf and other standard utilities.
Most of the standard utilities work on text files. The cut utility can be used to turn files with arbitrary line lengths into a set of text files containing the same data. The paste utility can be used to create (or recreate) files with arbitrary line lengths. For example, if file contains long lines:

```
cut -b 1-500 -n file > file1
cut -b 501- -n file > file2
```

creates file1 (a text file) with lines no longer than 500 bytes (plus the <newline>) and file2 that contains the remainder of the data from file. Note that file2 is not a text file if there are lines in file that are longer than $500+\{$ LINE_MAX $\}$ bytes. The original file can be recreated from file1 and file2 using the command:

```
paste -d "\0" file1 file2 > file
```

The commands:

```
paste -d "\0" ...
paste -d "" ...
```

are not necessarily equivalent; the latter is not specified by this volume of IEEE Std 1003.1-200x and may result in an error. The construct ' $\backslash 0$ ' is used to mean "no separator" because historical versions of paste did not follow the syntax guidelines, and the command:

```
paste -d"" ...
```

could not be handled properly by getopt ().

## EXAMPLES

1. Write out a directory in four columns:
```
ls
paste - - - -
```

2. Combine pairs of lines from a file into single lines:
```
paste -s -d "\t\n" file
```

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

& \text { [-o outfile] [-p num] [-r rejectfile] [file] }
\end{aligned}
$$

## DESCRIPTION

The patch utility shall read a source (patch) file containing any of four forms of difference (diff) listings produced by the diff utility (normal, copied context, unified context, or in the style of ed) and apply those differences to a file. By default, patch shall read from the standard input.
The patch utility shall attempt to determine the type of the diff listing, unless overruled by a $-\mathbf{c}$, $-\mathbf{e},-\mathbf{n}$, or $-\mathbf{u}$ option.
If the patch file contains more than one patch, patch shall attempt to apply each of them as if they came from separate patch files. (In this case, the application shall ensure that the name of the patch file is determinable for each diff listing.)

## OPTIONS

The patch utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-b Save a copy of the original contents of each modified file, before the differences are applied, in a file of the same name with the suffix .orig appended to it. If the file already exists, it shall be overwritten; if multiple patches are applied to the same file, the .orig file shall be written only for the first patch. When the -o outfile option is also specified, file.orig shall not be created but, if outfile already exists, outfile.orig shall be created.
-c Interpret the patch file as a copied context difference (the output of the utility diff when the -c or - C options are specified).
-d dir Change the current directory to dir before processing as described in the EXTENDED DESCRIPTION section.
-D define
Mark changes with one of the following $C$ preprocessor constructs:
\#ifdef define
\#endif
\#ifndef define
\#endif
optionally combined with the C preprocessor construct \#else. If the patched file is processed with the C preprocessor, where the macro define is defined, the output shall contain the changes from the patch file; otherwise, the output shall not contain the patches specified in the patch file.
-e Interpret the patch file as an ed script, rather than a diff script.
-i patchfile Read the patch information from the file named by the pathname patchfile, rather than the standard input.

| 27197 | $-\mathbf{1}$ | (The letter ell.) Cause any sequence of <blank>s in the difference script to match <br> any sequence of <blank>s in the input file. Other characters shall be matched <br> exactly. |
| :--- | :--- | :--- |
| 27198 | Interpret the script as a normal difference. |  |

## STDIN

See the INPUT FILES section.

## INPUT FILES

Input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of patch:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
LC_TIME Determine the locale for recognizing the format of file timestamps written by the diff utility in a context-difference input file.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used for diagnostic and informational messages.

## OUTPUT FILES

The output of the patch utility, the save files (.orig suffixes), and the reject files (.rej suffixes) shall be text files.

## EXTENDED DESCRIPTION

A patch file may contain patching instructions for more than one file; filenames shall be determined as specified in Filename Determination (on page 695). When the -b option is specified, for each patched file, the original shall be saved in a file of the same name with the suffix .orig appended to it.
For each patched file, a reject file may also be created as noted in Patch Application (on page 695). In the absence of a -r option, the name of this file shall be formed by appending the suffix .rej to the original filename.

## Patch File Format

The patch file shall contain zero or more lines of header information followed by one or more patches. Each patch shall contain zero or more lines of filename identification in the format produced by the $-\mathbf{c},-\mathbf{C},-\mathbf{u}$, or $-\mathbf{U}$ options of the diff utility, and one or more sets of diff output, which are customarily called hunks.
The patch utility shall recognize the following expression in the header information:

## Index: pathname

The file to be patched is named pathname.
If all lines (including headers) within a patch begin with the same leading sequence of <blank>s, the patch utility shall remove this sequence before proceeding. Within each patch, if the type of difference is common context, the patch utility shall recognize the following expressions:
*** filename timestamp
The patches arose from filename.
--- filename timestamp
The patches should be applied to filename.
If the type of difference is unified context, the patch utility shall recognize the following expressions:
--- filename timestamp
The patches arose from filename.
+++ filename timestamp
The patches should be applied to filename.
Each hunk within a patch shall be the diff output to change a line range within the original file. The line numbers for successive hunks within a patch shall occur in ascending order.

## Filename Determination

If no file operand is specified, patch shall perform the following steps to determine the filename to use:

1. If the type of diff is context, the patch utility shall delete pathname components (as specified by the $-\mathbf{p}$ option) from the filename on the line beginning with "***" (if copied context) or "---" (if unified context), then test for the existence of this file relative to the current directory (or the directory specified with the $-\mathbf{d}$ option). If the file exists, the patch utility shall use this filename.
2. If the type of diff is context, the patch utility shall delete the pathname components (as specified by the $-\mathbf{p}$ option) from the filename on the line beginning with "---" (if copied context) or "+++" (if unified context), then test for the existence of this file relative to the current directory (or the directory specified with the $-\mathbf{d}$ option). If the file exists, the patch utility shall use this filename.
3. If the header information contains a line beginning with the string Index:, the patch utility shall delete pathname components (as specified by the $-\mathbf{p}$ option) from this line, then test for the existence of this file relative to the current directory (or the directory specified with the -d option). If the file exists, the patch utility shall use this filename.

## xSI

4. If an SCCS directory exists in the current directory, patch shall attempt to perform a get -e SCCS/s.filename command to retrieve an editable version of the file. If the file exists, the patch utility shall use this filename.
5. The patch utility shall write a prompt to standard output and request a filename interactively from the controlling terminal (for example, /dev/tty).

## Patch Application

If the $-\mathbf{c},-\mathbf{e},-\mathbf{n}$, or $-\mathbf{u}$ option is present, the patch utility shall interpret information within each hunk as a copied context difference, an ed difference, a normal difference, or a unified context difference, respectively. In the absence of any of these options, the patch utility shall determine the type of difference based on the format of information within the hunk.
For each hunk, the patch utility shall begin to search for the place to apply the patch at the line number at the beginning of the hunk, plus or minus any offset used in applying the previous hunk. If lines matching the hunk context are not found, patch shall scan both forwards and backwards at least 1000 bytes for a set of lines that match the hunk context.
If no such place is found and it is a context difference, then another scan shall take place, ignoring the first and last line of context. If that fails, the first two and last two lines of context shall be ignored and another scan shall be made. Implementations may search more extensively for installation locations.
If no location can be found, the patch utility shall append the hunk to the reject file. A rejected hunk that is a copied context difference, an ed difference, or a normal difference shall be written in copied-context-difference format regardless of the format of the patch file. It is implementation-defined whether a rejected hunk that is a unified context difference is written in copied-context-difference format or in unified-context-difference format. If the input was a
normal or ed-style difference, the reject file may contain differences with zero lines of context. The line numbers on the hunks in the reject file may be different from the line numbers in the patch file since they shall reflect the approximate locations for the failed hunks in the new file rather than the old one.

If the type of patch is an ed diff, the implementation may accomplish the patching by invoking the ed utility.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
1 One or more lines were written to a reject file.
$>1$ An error occurred.

## CONSEQUENCES OF ERRORS

Patches that cannot be correctly placed in the file shall be written to a reject file.

## APPLICATION USAGE

The $-\mathbf{R}$ option does not work with ed scripts because there is too little information to reconstruct the reverse operation.

The -p option makes it possible to customize a patch file to local user directory structures without manually editing the patch file. For example, if the filename in the patch file was:
/curds/whey/src/blurfl/blurfl.c
Setting -p $\mathbf{0}$ gives the entire pathname unmodified; $-\mathbf{p} \mathbf{1}$ gives:
curds/whey/src/blurfl/blurfl.c
without the leading slash, $-\mathbf{p} 4$ gives:
blurfl/blurfl.c
and not specifying $-\mathbf{p}$ at all gives:
blurfl.c.

## EXAMPLES

None.

## RATIONALE

Some of the functionality in historical patch implementations was not specified. The following documents those features present in historical implementations that have not been specified.
A deleted piece of functionality was the ' + ' pseudo-option allowing an additional set of options and a patch file operand to be given. This was seen as being insufficiently useful to standardize.
In historical implementations, if the string "Prereq: " appeared in the header, the patch utility would search for the corresponding version information (the string specified in the header, delimited by <blank>s or the beginning or end of a line or the file) anywhere in the original file. This was deleted as too simplistic and insufficiently trustworthy a mechanism to standardize. For example, if:

Prereq: 1.2
were in the header, the presence of a delimited 1.2 anywhere in the file would satisfy the prerequisite.
The following options were dropped from historical implementations of patch as insufficiently useful to standardize:

| -b | The $-\mathbf{b}$ option historically provided a method for changing the name extension of <br> the backup file from the default .orig. This option has been modified and retained <br> in this volume of IEEE Std 1003.1-200x. |
| :--- | :--- |
| -F | The $-\mathbf{F}$ option specified the number of lines of a context diff to ignore when <br> searching for a place to install a patch. |
| -f | The $-\mathbf{f}$ option historically caused patch not to request additional information from <br> the user. |
| -r The $-\mathbf{r}$ option historically provided a method of overriding the extension of the |  |
| reject file from the default .rej. |  |$\quad$| The $-\mathbf{s}$ option historically caused patch to work silently unless an error occurred. |
| :--- |
| -s |

In some file system implementations, the saving of a .orig file may produce unwanted results. In the case of 12,13 , or 14 -character filenames (on file systems supporting 14-character maximum filenames), the .orig file overwrites the new file. The reject file may also exceed this filename limit. It was suggested, due to some historical practice, that a tilde ( $\left.\quad{ }^{\sim}\right)^{\prime}$ ) suffix be used instead of . orig and some other character instead of the rej suffix. This was rejected because it is not obvious to the user which file is which. The suffixes .orig and .rej are clearer and more understandable.

The -b option has the opposite sense in some historical implementations-do not save the .orig file. The default case here is not to save the files, making patch behave more consistently with the other standard utilities.

The $-\mathbf{w}$ option in early proposals was changed to -1 to match historical practice.
The $-\mathbf{N}$ option was included because without it, a non-interactive application cannot reject previously applied patches. For example, if a user is piping the output of diff into the patch utility, and the user only wants to patch a file to a newer version non-interactively, the $-\mathbf{N}$ option is required.

Changes to the -1 option description were proposed to allow matching across <newline>s in addition to just <blank>s. Since this is not historical practice, and since some ambiguities could result, it is suggested that future developments in this area utilize another option letter, such as $-\mathbf{L}$.

The -u option of GNU patch has been added, along with support for unified context formats.

## CHANGE HISTORY

First released in Issue 4.

## Issue 5

The FUTURE DIRECTIONS section is added.

## Issue 6

This utility is marked as part of the User Portability Utilities option.
The description of the $-\mathbf{D}$ option and the steps in Filename Determination are changed to match historical practice as defined in the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/34 is applied, clarifying the way that the
patch utility performs ifdef selection for the - D option.
Issue 7
The patch utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-103 and SD5-XCU-ERN-120 are applied, adding the $-\mathbf{u}$ option.

NAME
pathchk - check pathnames

## SYNOPSIS

```
    pathchk [-p] [-P] pathname...
```

## DESCRIPTION

The pathchk utility shall check that one or more pathnames are valid (that is, they could be used to access or create a file without causing syntax errors) and portable (that is, no filename truncation results). More extensive portability checks are provided by the $-\mathbf{p}$ and $-\mathbf{P}$ options.
By default, the pathchk utility shall check each component of each pathname operand based on the underlying file system. A diagnostic shall be written for each pathname operand that:

- Is longer than $\left\{P A T H \_M A X\right\}$ bytes (see Pathname Variable Values in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, <limits.h>)
- Contains any component longer than \{NAME_MAX\} bytes in its containing directory
- Contains any component in a directory that is not searchable
- Contains any character in any component that is not valid in its containing directory

The format of the diagnostic message is not specified, but shall indicate the error detected and the corresponding pathname operand.
It shall not be considered an error if one or more components of a pathname operand do not exist as long as a file matching the pathname specified by the missing components could be created that does not violate any of the checks specified above.

## OPTIONS

The pathchk utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-p Instead of performing checks based on the underlying file system, write a diagnostic for each pathname operand that:

- Is longer than 1 POSIX_PATH $\angle M A X\}$ bytes (see Minimum Values in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 13, Headers, <limits.h>)
- Contains any component longer than \{_POSIX_NAME_MAX\} bytes
- Contains any character in any component that is not in the portable filename character set
-P Write a diagnostic for each pathname operand that:
- Contains a component whose first character is the hyphen character
- Is empty

## OPERANDS

The following operand shall be supported:
pathname A pathname to be checked.

## STDIN

Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of pathchk:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.
OUTPUT FILES
None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All pathname operands passed all of the checks.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

 Default.
## APPLICATION USAGE

The test utility can be used to determine whether a given pathname names an existing file; it does not, however, give any indication of whether or not any component of the pathname was truncated in a directory where the _POSIX_NO_TRUNC feature is not in effect. The pathchk utility does not check for file existence; it performs checks to determine whether a pathname does exist or could be created with no pathname component truncation.

The noclobber option in the shell (see the set special built-in) can be used to atomically create a file. As with all file creation semantics in the System Interfaces volume of IEEE Std 1003.1-200x, it guarantees atomic creation, but still depends on applications to agree on conventions and cooperate on the use of files after they have been created.

To verify that a pathname meets the requirements of filename portability, applications should use both the $-\mathbf{p}$ and $-\mathbf{P}$ options together.

## EXAMPLES

To verify that all pathnames in an imported data interchange archive are legitimate and unambiguous on the current system:

```
# This example assumes that no pathnames in the archive
# contain <newline> characters.
pax -f archive | sed -e 's/[^[:alnum:]]/\\&/g' | xargs pathchk
if [ $? -eq 0 ]
then
    pax -r -f archive
else
    echo Investigate problems before importing files.
    exit 1
fi
```

To verify that all files in the current directory hierarchy could be moved to any system conforming to the System Interfaces volume of IEEE Std 1003.1-200x that also supports the pax utility:

```
find . -exec pathchk -p -P {}
if [ $? -eq 0 ]
then
    pax -w -f ../archive.
else
    echo Portable archive cannot be created.
    exit 1
fi
```

To verify that a user-supplied pathname names a readable file and that the application can create a file extending the given path without truncation and without overwriting any existing file:

```
case $- in
    *C*) reset="";;
    *) reset="set +C"
        set -C;;
esac
test -r "$path" && pathchk "$path.out" &&
    rm "$path.out" > "$path.out"
if [ $? -ne 0 ]; then
    printf "%s: %s not found or %s.out fails \
creation checks.\n" $0 "$path" "$path"
    $reset # Reset the noclobber option in case a trap
            # on EXIT depends on it.
    exit 1
fi
$reset
PROCESSING < "$path" > "$path.out"
```

The following assumptions are made in this example:

1. PROCESSING represents the code that is used by the application to use \$path once it is verified that \$path.out works as intended.
2. The state of the noclobber option is unknown when this code is invoked and should be set on exit to the state it was in when this code was invoked. (The reset variable is used in this example to restore the initial state.)
3. Note the usage of:
```
rm "$path.out" > "$path.out"
```

a. The pathchk command has already verified, at this point, that \$path.out is not truncated.
b. With the noclobber option set, the shell verifies that \$path.out does not already exist before invoking $r m$.
c. If the shell succeeded in creating \$path.out, $r m$ removes it so that the application can create the file again in the PROCESSING step.
d. If the PROCESSING step wants the file to exist already when it is invoked, the:

```
rm "$path.out" > "$path.out"
```

should be replaced with:
> "\$path. out"
which verifies that the file did not already exist, but leaves \$path.out in place for use by PROCESSING.

## RATIONALE

The pathchk utility was new for the ISO POSIX-2:1993 standard. It, along with the set -C(noclobber) option added to the shell, replaces the mktemp, validfnam, and create utilities that appeared in early proposals. All of these utilities were attempts to solve several common problems:

- Verify the validity (for several different definitions of "valid") of a pathname supplied by a user, generated by an application, or imported from an external source.
- Atomically create a file.
- Perform various string handling functions to generate a temporary filename.

The create utility, included in an early proposal, provided checking and atomic creation in a single invocation of the utility; these are orthogonal issues and need not be grouped into a single utility. Note that the noclobber option also provides a way of creating a lock for process synchronization; since it provides an atomic create, there is no race between a test for existence and the following creation if it did not exist.

Having a function like tmpnam () in the ISOC standard is important in many high-level languages. The shell programming language, however, has built-in string manipulation facilities, making it very easy to construct temporary filenames. The names needed obviously depend on the application, but are frequently of a form similar to:
\$TMPDIR/application_abbreviation\$\$.suffix
In cases where there is likely to be contention for a given suffix, a simple shell for or while loop can be used with the shell noclobber option to create a file without risk of collisions, as long as applications trying to use the same filename name space are cooperating on the use of files after they have been created.

For historical purposes, - $\mathbf{p}$ does not check for the use of the hyphen character as the first character in a component of the pathname, or for an empty pathname operand.

NAME
pax - portable archive interchange

## SYNOPSIS

```
pax [-dv] [-c|-n] [-H|-L] [-o options] [-f archive] [-s replstr]...
        [pattern...]
    pax \(-\mathrm{r}[-\mathrm{c} \mid-\mathrm{n}]\) [-dikuv] [-H|-L] [-f archive] [-o options]... [-p string]...
            [-s replstr]... [pattern...]
pax -w[-dituvX] [-H|-L] [-b blocksize] [[-a][-f archive]] [-o options]...
    [-s replstr]... [-x format] [file...]
pax \(-\mathrm{r}-\mathrm{w}[-\mathrm{diklntuvX}][-\mathrm{H} \mid-\mathrm{L}]\) [-o options]... [-p string]...
    [-s replstr]... [file...] directory
```

## DESCRIPTION

The pax utility shall read, write, and write lists of the members of archive files and copy directory hierarchies. A variety of archive formats shall be supported; see the $-\mathbf{x}$ format option.

The action to be taken depends on the presence of the $-\mathbf{r}$ and $-\mathbf{w}$ options. The four combinations of $-\mathbf{r}$ and $-\mathbf{w}$ are referred to as the four modes of operation. list, read, write, and copy modes, corresponding respectively to the four forms shown in the SYNOPSIS section.
list In list mode (when neither -r nor -w are specified), pax shall write the names of the members of the archive file read from the standard input, with pathnames matching the specified patterns, to standard output. If a named file is of type directory, the file hierarchy rooted at that file shall be listed as well.
read In read mode (when $-\mathbf{r}$ is specified, but $-\mathbf{w}$ is not), pax shall extract the members of the archive file read from the standard input, with pathnames matching the specified patterns. If an extracted file is of type directory, the file hierarchy rooted at that file shall be extracted as well. The extracted files shall be created performing pathname resolution with the directory in which pax was invoked as the current working directory.

If an attempt is made to extract a directory when the directory already exists, this shall not be considered an error. If an attempt is made to extract a FIFO when the FIFO already exists, this shall not be considered an error.
The ownership, access, and modification times, and file mode of the restored files are discussed under the - $\mathbf{p}$ option.
write In write mode (when $-\mathbf{w}$ is specified, but $-\mathbf{r}$ is not), pax shall write the contents of the file operands to the standard output in an archive format. If no file operands are specified, a list of files to copy, one per line, shall be read from the standard input and each entry in this list shall be processed as if it had been a file operand on the command line. A file of type directory shall include all of the files in the file hierarchy rooted at the file.
copy In copy mode (when both $-\mathbf{r}$ and $-\mathbf{w}$ are specified), pax shall copy the file operands to the destination directory.

If no file operands are specified, a list of files to copy, one per line, shall be read from the standard input. A file of type directory shall include all of the files in the file hierarchy rooted at the file.
The effect of the copy shall be as if the copied files were written to a pax format archive file and then subsequently extracted, except that there may be hard links
between the original and the copied files. If the destination directory is a subdirectory of one of the files to be copied, the results are unspecified. If the destination directory is a file of a type not defined by the System Interfaces volume of IEEE Std 1003.1-200x, the results are implementation-defined; otherwise, it shall be an error for the file named by the directory operand not to exist, not be writable by the user, or not be a file of type directory.
In read or copy modes, if intermediate directories are necessary to extract an archive member, pax shall perform actions equivalent to the mkdir() function defined in the System Interfaces volume of IEEE Std 1003.1-200x, called with the following arguments:

- The intermediate directory used as the path argument
- The value of the bitwise-inclusive OR of S_IRWXU, S_IRWXG, and S_IRWXO as the mode argument
If any specified pattern or file operands are not matched by at least one file or archive member, pax shall write a diagnostic message to standard error for each one that did not match and exit with a non-zero exit status.

The archive formats described in the EXTENDED DESCRIPTION section shall be automatically detected on input. The default output archive format shall be implementation-defined.

A single archive can span multiple files. The pax utility shall determine, in an implementationdefined manner, what file to read or write as the next file.

If the selected archive format supports the specification of linked files, it shall be an error if these files cannot be linked when the archive is extracted, except that if the files to be linked are symbolic links and the system is not capable of making hard links to symbolic links, then separate copies of the symbolic link shall be created instead. For archive formats that do not store file contents with each name that causes a hard link, if the file that contains the data is not extracted during this pax session, either the data shall be restored from the original file, or a diagnostic message shall be displayed with the name of a file that can be used to extract the data. In traversing directories, pax shall detect infinite loops; that is, entering a previously visited directory that is an ancestor of the last file visited. When it detects an infinite loop, pax shall write a diagnostic message to standard error and shall terminate.

## OPTIONS

The pax utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of presentation of the $-\mathbf{0},-\mathbf{p}$, and - s options is significant.
The following options shall be supported:
-r Read an archive file from standard input.
-w Write files to the standard output in the specified archive format.
-a Append files to the end of the archive. It is implementation-defined which devices on the system support appending. Additional file formats unspecified by this volume of IEEE Std 1003.1-200x may impose restrictions on appending.
-b blocksize Block the output at a positive decimal integer number of bytes per write to the archive file. Devices and archive formats may impose restrictions on blocking. Blocking shall be automatically determined on input. Conforming applications shall not specify a blocksize value larger than 32256. Default blocking when creating archives depends on the archive format. (See the -x option below.)
-c Match all file or archive members except those specified by the pattern or file operands.

| 27698 | -d | Cause files of type directory being copied or archived or archive members of type |
| :---: | :---: | :---: |
| 27699 |  | directory being extracted or listed to match only the file or archive member itself |
| 27700 |  | and not the file hierarchy rooted at the file. |
| 27701 | -f archive | Specify the pathname of the input or output archive, overriding the default |
| 27702 |  | standard input (in list or read modes) or standard output (write mode). |
| 27703 | -H | If a symbolic link referencing a file of type directory is specified on the command |
| 27704 |  | line, pax shall archive the file hierarchy rooted in the file referenced by the link, |
| 27705 |  | using the name of the link as the root of the file hierarchy. Otherwise, if a symbolic |
| 27706 |  | link referencing a file of any other file type which pax can normally archive is |
| 27707 |  | specified on the command line, then pax shall archive the file referenced by the |
| 27708 |  | link, using the name of the link. The default behavior, when neither $-\mathbf{H}$ or -L are |
| 27709 |  | specified, shall be to archive the symbolic link itself. |
| 27710 | -i | Interactively rename files or archive members. For each archive member matching |
| 27711 |  | a pattern operand or file matching a file operand, a prompt shall be written to the |
| 27712 |  | file /dev/tty. The prompt shall contain the name of the file or archive member, but |
| 27713 |  | the format is otherwise unspecified. A line shall then be read from /dev/tty. If this |
| 27714 |  | line is blank, the file or archive member shall be skipped. If this line consists of a |
| 27715 |  | single period, the file or archive member shall be processed with no modification |
| 27716 |  | to its name. Otherwise, its name shall be replaced with the contents of the line. The |
| 27717 |  | pax utility shall immediately exit with a non-zero exit status if end-of-file is |
| 27718 |  | encountered when reading a response or if /dev/tty cannot be opened for reading |
| 27719 |  | and writing. |
| 27720 |  | The results of extracting a hard link to a file that has been renamed during |
| 27721 |  | extraction are unspecified. |
| 27722 | -k | Prevent the overwriting of existing files. |
| 27723 | -1 | (The letter ell.) In copy mode, hard links shall be made between the source and |
| 27724 |  | destination file hierarchies whenever possible. If specified in conjunction with $-\mathbf{H}$ |
| 27725 |  | or $-\mathbf{L}$, when a symbolic link is encountered, the hard link created in the destination |
| 27726 |  | file hierarchy shall be to the file referenced by the symbolic link. If specified when |
| 27727 |  | neither $-\mathbf{H}$ nor $-\mathbf{L}$ is specified, when a symbolic link is encountered, the |
| 27728 |  | mplementation shall create a hard link to the symbolic link in the source file |
| 27729 |  | hierarchy or copy the symbolic link to the destination. |
| 27730 | -L | If a symbolic link referencing a file of type directory is specified on the command |
| 27731 |  | line or encountered during the traversal of a file hierarchy, pax shall archive the file |
| 27732 |  | hierarchy rooted in the file referenced by the link, using the name of the link as the |
| 27733 |  | root of the file hierarchy. Otherwise, if a symbolic link referencing a file of any |
| 27734 |  | other file type which pax can normally archive is specified on the command line or |
| 27735 |  | encountered during the traversal of a file hierarchy, pax shall archive the file |
| 27736 |  | referenced by the link, using the name of the link. The default behavior, when |
| 27737 |  | neither $-\mathbf{H}$ or $-\mathbf{L}$ are specified, shall be to archive the symbolic link itself. |
| 27738 | -n | Select the first archive member that matches each pattern operand. No more than |
| 27739 |  | one archive member shall be matched for each pattern (although members of type |
| 27740 |  | directory shall still match the file hierarchy rooted at that file). |
| 27741 | -o options | Provide information to the implementation to modify the algorithm for extracting |
| 27742 |  | or writing files. The value of options shall consist of one or more comma-separated |
| 27743 |  | keywords of the form: |

```
keyword[[:]=value][,keyword[[:]=value], ...]
```

Some keywords apply only to certain file formats, as indicated with each description. Use of keywords that are inapplicable to the file format being
processed produces undefined results.
Keywords in the options argument shall be a string that would be a valid portable filename as described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.276, Portable Filename Character Set.

Note: Keywords are not expected to be filenames, merely to follow the same character composition rules as portable filenames.

Keywords can be preceded with white space. The value field shall consist of zero or more characters; within value, the application shall precede any literal comma with a backslash, which shall be ignored, but preserves the comma as part of value. A comma as the final character, or a comma followed solely by white space as the final characters, in options shall be ignored. Multiple - o options can be specified; if keywords given to these multiple -o options conflict, the keywords and values appearing later in command line sequence shall take precedence and the earlier shall be silently ignored. The following keyword values of options shall be supported for the file formats as indicated:

## delete=pattern

(Applicable only to the -x pax format.) When used in write or copy mode, pax shall omit from extended header records that it produces any keywords matching the string pattern. When used in read or list mode, pax shall ignore any keywords matching the string pattern in the extended header records. In both cases, matching shall be performed using the pattern matching notation described in Section 2.13.1 and Section 2.13.2 (on page 63). For example:
-o delete=security.*
would suppress security-related information. See pax Extended Header for extended header record keyword usage.

When multiple -odelete=pattern options are specified, the patterns shall be additive; all keywords matching the specified string patterns shall be omitted from extended header records that pax produces.

## exthdr.name $=$ string

(Applicable only to the - $\mathbf{x}$ pax format.) This keyword allows user control over the name that is written into the ustar header blocks for the extended header produced under the circumstances described in pax Header Block (on page 716). The name shall be the contents of string, after the following character substitutions have been made:

| string <br> Includes: | Replaced By: |
| :--- | :--- |
| $\% \mathrm{~d}$ | The directory name of the file, equivalent to the result of the <br> dirname utility on the translated pathname. |
| $\% \mathrm{f}$ | The filename of the file, equivalent to the result of the <br> basename utility on the translated pathname. |
| $\% \mathrm{p}$ | The process ID of the pax process. <br> $\mathrm{A}^{\prime} \%^{\prime}$ ' character. |

Any other ${ }^{\prime} \%^{\prime}$ ' characters in string produce undefined results.
If no -o exthdr.name=string is specified, pax shall use the following default value:
\%d/PaxHeaders.\%p/\%f

## globexthdr.name=string

(Applicable only to the -x pax format.) When used in write or copy mode with the appropriate options, pax shall create global extended header records with ustar header blocks that will be treated as regular files by previous versions of pax. This keyword allows user control over the name that is written into the ustar header blocks for global extended header records. The name shall be the contents of string, after the following character substitutions have been made:

| string <br> Includes: | Replaced By: |
| :---: | :---: |
| \%n | An integer that represents the sequence number of the global extended header record in the archive, starting at 1. |
| \%p | The process ID of the pax process. |
| \%\% | $A^{\prime} \%$ ' character. |

Any other ${ }^{\prime} \%{ }^{\prime}$ characters in string produce undefined results.
If no -o globexthdr.name=string is specified, pax shall use the following default value:
\$TMPDIR/GlobalHead. $\circ$ ㄹp. $\%$ n
where $\$ T M P D I R$ represents the value of the TMPDIR environment variable. If TMPDIR is not set, pax shall use /tmp.
invalid=action
(Applicable only to the -x pax format.) This keyword allows user control over the action pax takes upon encountering values in an extended header record that, in read or copy mode, are invalid in the destination hierarchy or, in list mode, cannot be written in the codeset and current locale of the implementation. The following are invalid values that shall be recognized by pax:

- In read or copy mode, a filename or link name that contains character encodings invalid in the destination hierarchy. (For example, the name may contain embedded NULs.)
- In read or copy mode, a filename or link name that is longer than the maximum allowed in the destination hierarchy (for either a pathname component or the entire pathname).
- In list mode, any character string value (filename, link name, user name, and so on) that cannot be written in the codeset and current locale of the implementation.

The following mutually-exclusive values of the action argument are supported:
binary In write mode, pax shall generate a hdrcharset=BINARY extended header record for each file with a filename, link name, group name, owner name, or any other field in an extended header record that cannot be translated to the UTF-8 codeset, allowing the archive to contain the files with unencoded extended header record values. In read or copy mode, pax shall use the values specified in the header without translation, regardless of whether this may overwrite an existing file with a valid name. In list mode, pax shall behave identically to the bypass action.
bypass In read or copy mode, pax shall bypass the file, causing no change to the destination hierarchy. In list mode, pax shall write all requested valid values for the file, but its method for writing invalid values is unspecified.
rename In read or copy mode, pax shall act as if the -i option were in effect for each file with invalid filename or link name values, allowing the user to provide a replacement name interactively. In list mode, pax shall behave identically to the bypass action.
UTF-8 When used in read, copy, or list mode and a filename, link name, owner name, or any other field in an extended header record cannot be translated from the pax UTF-8 codeset format to the codeset and current locale of the implementation, pax shall use the actual UTF-8 encoding for the name. If a hdrcharset extended header record is in effect for this file, the character set specified by that record shall be used instead of UTF-8. If a hdrcharset=BINARY extended header record is in effect for this file, no translation shall be performed.
write In read or copy mode, $p a x$ shall write the file, translating the name, regardless of whether this may overwrite an existing file with a valid name. In list mode, pax shall behave identically to the bypass action.
If no -o invalid=option is specified, pax shall act as if -oinvalid=bypass were specified. Any overwriting of existing files that may be allowed by the -oinvalid= actions shall be subject to permission ( $-\mathbf{p}$ ) and modification time $(-\mathbf{u})$ restrictions, and shall be suppressed if the $-\mathbf{k}$ option is also specified.
linkdata
(Applicable only to the $-\boldsymbol{x}$ pax format.) In write mode, pax shall write the contents of a file to the archive even when that file is merely a hard link to a file whose contents have already been written to the archive.

## listopt=format

This keyword specifies the output format of the table of contents produced when the $-\mathbf{v}$ option is specified in list mode. See List Mode Format Specifications (on page 712). To avoid ambiguity, the listopt=format shall be the only or final keyword=value pair in a -o option-argument; all characters in the remainder of the option-argument shall be considered part of the format string. When multiple -olistopt=format options are specified, the format strings shall be considered a single, concatenated string, evaluated in command line order.

## times

(Applicable only to the $-\mathbf{x}$ pax format.) When used in write or copy mode, pax shall include atime and mtime extended header records for each file. See pax Extended Header File Times (on page 720).
In addition to these keywords, if the $-\mathbf{x} p a x$ format is specified, any of the keywords and values defined in pax Extended Header (on page 717), including implementation extensions, can be used in -o option-arguments, in either of two modes:

## keyword=value

When used in write or copy mode, these keyword/value pairs shall be included at the beginning of the archive as typeflag $g$ global extended header records. When used in read or list mode, these keyword/value pairs shall act
as if they had been at the beginning of the archive as typeflag $\mathbf{g}$ global extended header records.
keyword:=value
When used in write or copy mode, these keyword/value pairs shall be included as records at the beginning of a typeflag $\mathbf{x}$ extended header for each file. (This shall be equivalent to the equal-sign form except that it creates no typeflag $\mathbf{g}$ global extended header records.) When used in read or list mode, these keyword/value pairs shall act as if they were included as records at the end of each extended header; thus, they shall override any global or filespecific extended header record keywords of the same names. For example, in the command:

```
pax -r -o "
gname:=mygroup,
" <archive
```

the group name will be forced to a new value for all files read from the archive.

The precedence of $-\mathbf{o}$ keywords over various fields in the archive is described in pax Extended Header Keyword Precedence (on page 720).
-p string Specify one or more file characteristic options (privileges). The string optionargument shall be a string specifying file characteristics to be retained or discarded on extraction. The string shall consist of the specification characters $a, e, m, o$ and p. Other implementation-defined characters can be included. Multiple characteristics can be concatenated within the same string and multiple $-\mathbf{p}$ options can be specified. The meaning of the specification characters are as follows:
a Do not preserve file access times.
e Preserve the user ID, group ID, file mode bits (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.168, File Mode Bits), access time, modification time, and any other implementation-defined file characteristics.
m Do not preserve file modification times.
Preserve the user ID and group ID.
Preserve the file mode bits. Other implementation-defined file mode attributes may be preserved.
In the preceding list, "preserye" indicates that an attribute stored in the archive shall be given to the extracted file, subject to the permissions of the invoking process. The access and modification times of the file shall be preserved unless otherwise specified with the $-\mathbf{p}$ option or not stored in the archive. All attributes that are not preserved shall be determined as part of the normal file creation action (see Section 17.1.4 (on page 4)).
If neither the e nor the o specification character is specified, or the user ID and group ID are not preserved for any reason, pax shall not set the S_ISUID and S_ISGID bits of the file mode.

If the preservation of any of these items fails for any reason, pax shall write a diagnostic message to standard error. Failure to preserve these items shall affect the final exit status, but shall not cause the extracted file to be deleted.
If file characteristic letters in any of the string option-arguments are duplicated or conflict with each other, the ones given last shall take precedence. For example, if $-\mathbf{p}$ eme is specified, file modification times are preserved.

| 27937 | -s replstr | Modify file or archive member names named by pattern or file operands according |
| :---: | :---: | :---: |
| 27938 |  | to the substitution expression replstr, using the syntax of the ed utility. The concepts |
| 27939 |  | of "address" and "line" are meaningless in the context of the pax utility, and shall |
| 27940 |  | not be supplied. The format shall be: |
| 27941 |  | -s /old/new/[gp] |
| 27942 |  | where as in ed, old is a basic regular expression and new can contain an ampersand, |
| 27943 |  | $' \backslash \mathrm{n}^{\prime}$ (where $n$ is a digit) back-references, or subexpression matching. The old |
| 27944 |  | string shall also be permitted to contain <newline>s. |
| 27945 |  | Any non-null character can be used as a delimiter (' /' shown here). Multiple -s |
| 27946 |  | expressions can be specified; the expressions shall be applied in the order |
| 27947 |  | specified, terminating with the first successful substitution. The optional trailing |
| 27948 |  | ' g ' is as defined in the ed utility. The optional trailing ' p ' shall cause successful |
| 27949 |  | substitutions to be written to standard error. File or archive member names that |
| 27950 |  | substitute to the empty string shall be ignored when reading and writing archives. |
| 27951 | -t | When reading files from the file system, and if the user has the permissions required by utime () to do so, set the access time of each file read to the access time that it had before being read by pax. |
| 27952 |  |  |
| 27953 |  |  |
| 27954 | -u | Ignore files that are older (having a less recent file modification time) than a preexisting file or archive member with the same name. In read mode, an archive |
| 27955 |  |  |
| 27956 |  | member with the same name as a file in the file system shall be extracted if the |
| 27957 |  | archive member is newer than the file. In write mode, an archive file member with |
| 27958 |  | the same name as a file in the file system shall be superseded if the file is newer |
| 27959 |  | than the archive member. If -a is also specified, this is accomplished by appending |
| 27960 |  | to the archive; otherwise, it is unspecified whether this is accomplished by actual |
| 27961 |  | replacement in the archive or by appending to the archive. In copy mode, the file |
| 27962 |  | in the destination hierarchy shall be replaced by the file in the source hierarchy or |
| 27963 |  | by a link to the file in the source hierarchy if the file in the source hierarchy is |
| 27964 |  | newer. |
| 27965 | -v | list mode, produce a verbose table of contents (see the STDOUT section). |
| 27966 |  | Otherwise, write archive member pathnames to standard error (see the STDERR |
| 27967 |  | sction). |
| 27968 | -x format | Specify the output archive format. The pax utility shall support the following formats: |
| 27969 |  |  |
| 27970 |  | cpio The cpio interchange format; see the EXTENDED DESCRIPTION |
| 27971 |  | section. The default blocksize for this format for character special |
| 27972 |  | archive files shall be 5120. Implementations shall support all |
| 27973 |  | blocksize values less than or equal to 32256 that are multiples of 512 . |
| 27974 |  | pax The pax interchange format; see the EXTENDED DESCRIPTION |
| 27975 |  | section. The default blocksize for this format for character special |
| 27976 |  | archive files shall be 5120. Implementations shall support all |
| 27977 |  | blocksize values less than or equal to 32256 that are multiples of 512. |
| 27978 |  | ustar The tar interchange format; see the EXTENDED DESCRIPTION |
| 27979 |  | section. The default blocksize for this format for character special |
| 27980 |  | archive files shall be 10240. Implementations shall support all |
| 27981 |  | blocksize values less than or equal to 32256 that are multiples of 512. |

Implementation-defined formats shall specify a default block size as well as any other block sizes supported for character special archive files.
Any attempt to append to an archive file in a format different from the existing
archive format shall cause pax to exit immediately with a non-zero exit status.
-X When traversing the file hierarchy specified by a pathname, pax shall not descend into directories that have a different device ID (st_dev; see the System Interfaces volume of IEEE Std 1003.1-200x, stat ()).

Specifying more than one of the mutually-exclusive options -H and -L shall not be considered an error and the last option specified shall determine the behavior of the utility.

The options that operate on the names of files or archive members ( $-\mathbf{c},-\mathbf{i},-\mathbf{n},-\mathbf{s},-\mathbf{u}$, and $-\mathbf{v}$ ) shall interact as follows. In read mode, the archive members shall be selected based on the userspecified pattern operands as modified by the $-\mathbf{c},-\mathbf{n}$, and $-\mathbf{u}$ options. Then, any $-\mathbf{s}$ and $-\mathbf{i}$ options shall modify, in that order, the names of the selected files. The $-\mathbf{v}$ option shall write names resulting from these modifications.
In write mode, the files shall be selected based on the user-specified pathnames as modified by the $-\mathbf{n}$ and $-\mathbf{u}$ options. Then, any $-\mathbf{s}$ and $\mathbf{- i}$ options shall modify, in that order, the names of these selected files. The $-\mathbf{v}$ option shall write names resulting from these modifications.
If both the $-\mathbf{u}$ and $-\mathbf{n}$ options are specified, pax shall not consider a file selected unless it is newer than the file to which it is compared.

## List Mode Format Specifications

In list mode with the -o listopt=format option, the format argument shall be applied for each selected file. The pax utility shall append a <newline> to the listopt output for each selected file. The format argument shall be used as the format string described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation, with the exceptions 1. through 5. defined in the EXTENDED DESCRIPTION section of printf, plus the following exceptions:
6. The sequence (keyword) can occur before a format conversion specifier. The conversion argument is defined by the value of keyword. The implementation shall support the following keywords:

- Any of the Field Name entries in Table 4-13 and Table 4-15 (on page 724). The implementation may support the cpio keywords without the leading $\mathbf{c}_{-}$in addition to the form required by Table $4-15$ (on page 724).
- Any keyword defined for the extended header in pax Extended Header (on page 717).
- Any keyword provided as an implementation-defined extension within the extended header defined in pax Extended Header (on page 717).
For example, the sequence "\% (charset) $s$ " is the string value of the name of the character set in the extended header.
The result of the keyword conversion argument shall be the value from the applicable header field or extended header, without any trailing NULs.
All keyword values used as conversion arguments shall be translated from the UTF-8 encoding (or alternative encoding specified by any hdrcharset extended header record) to the character set appropriate for the local file system, user database, and so on, as applicable.

7. An additional conversion specifier character, $T$, shall be used to specify time formats. The $T$ conversion specifier character can be preceded by the sequence (keyword=subformat), where subformat is a date format as defined by date operands. The default keyword shall be mtime and the default subformat shall be:
$\% \mathrm{~b}$ \%e $\% \mathrm{H}: \% \mathrm{M} \% \mathrm{Y}$
8. An additional conversion specifier character, $M$, shall be used to specify the file mode string as defined in $l s$ Standard Output. If (keyword) is omitted, the mode keyword shall be used. For example, $\% .1 \mathrm{M}$ writes the single character corresponding to the <entry type> field of the $l s-1$ command.
9. An additional conversion specifier character, $D$, shall be used to specify the device for block or special files, if applicable, in an implementation-defined format. If not applicable, and (keyword) is specified, then this conversion shall be equivalent to $\%$ (keyword) u. If not applicable, and (keyword) is omitted, then this conversion shall be equivalent to <space>.
10. An additional conversion specifier character, $F$, shall be used to specify a pathname. The $F$ conversion character can be preceded by a sequence of comma-separated keywords:
(keyword[,keyword] . .. )
The values for all the keywords that are non-null shall be concatenated together, each separated by a ' /'. The default shall be (path) if the keyword path is defined; otherwise, the default shall be (prefix,name).
11. An additional conversion specifier character, $L$, shall be used to specify a symbolic link expansion. If the current file is a symbolic link, then \%L shall expand to:
```
"\%s \(\rightarrow\) \%s", <value of keyword>, <contents of link>
```

Otherwise, the $\% \mathrm{~L}$ conversion specification shall be the equivalent of $\% \mathrm{~F}$.

## OPERANDS

The following operands shall be supported:
directory The destination directory pathname for copy mode.
file A pathname of a file to be copied or archived.
pattern A pattern matching one or more pathnames of archive members. A pattern must be given in the name-generating notation of the pattern matching notation in Section 2.13 (on page 62), including the filename expansion rules in Section 2.13.3 (on page 63). The default, if no pattern is specified, is to select all members in the archive.

## STDIN

In write mode, the standard input shall be used only if no file operands are specified. It shall be a text file containing a list of pathnames, one per line, without leading or trailing <blank>s.
In list and read modes, if $-\mathbf{f}$ is not specified, the standard input shall be an archive file.
Otherwise, the standard input shall not be used.

## INPUT FILES

The input file named by the archive option-argument, or standard input when the archive is read from there, shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section or some other implementation-defined format.

The file /dev/tty shall be used to write prompts and read responses.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of pax:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements used in the pattern matching expressions for the pattern operand, the basic regular expression for the -s option, and the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the behavior of character classes used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category, and pattern matching.
LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

LC_TIME Determine the format and contents of date and time strings when the $-\mathbf{v}$ option is specified.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
$T M P D I R \quad$ Determine the pathname that provides part of the default global extended header record file, as described for the -o globexthdr= keyword in the OPTIONS section.
$T Z \quad$ Determine the timezone used to calculate date and time strings when the $-\mathbf{v}$ option is specified. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

In write mode, if $-\mathbf{f}$ is not specified, the standard output shall be the archive formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format (see $-\mathbf{x}$ format).

In list mode, when the -olistopt=format has been specified, the selected archive members shall be written to standard output using the format described under List Mode Format Specifications (on page 712). In list mode without the -olistopt=format option, the table of contents of the selected archive members shall be written to standard output using the following format:
"\%s n ", <pathname>
If the $\mathbf{- v}$ option is specified in list mode, the table of contents of the selected archive members shall be written to standard output using the following formats.
For pathnames representing hard links to previous members of the archive:
"\%s $\Delta==\Delta \% s \backslash n ",<l s-l$ listing>, <linkname>
For all other pathnames:
"\%s\n", <ls -l listing>
where <ls -1 listing> shall be the format specified by the $l s$ utility with the -1 option. When writing pathnames in this format, it is unspecified what is written for fields for which the underlying archive format does not have the correct information, although the correct number of <blank>-separated fields shall be written.

In list mode, standard output shall not be buffered more than a line at a time.

## STDERR

If $\mathbf{- v}$ is specified in read, write, or copy modes, pax shall write the pathnames it processes to the standard error output using the following format:
"\%s n n", <pathname>
These pathnames shall be written as soon as processing is begun on the file or archive member, and shall be flushed to standard error. The trailing <newline>, which shall not be buffered, is written when the file has been read or written.

If the -s option is specified, and the replacement string has a trailing ' $p^{\prime}$, substitutions shall be written to standard error in the following format:
"\%s $\Delta \gg \Delta \% s \backslash n ", ~<o r i g i n a l ~ p a t h n a m e>, ~<n e w ~ p a t h n a m e>~$
In all operating modes of pax, optional messages of unspecified format concerning the input archive format and volume number, the number of files, blocks, volumes, and media parts as well as other diagnostic messages may be written to standard error.
In all formats, for both standard output and standard error, it is unspecified how non-printable characters in pathnames or link names are written.

When using the -xpax archive format, if a filename, link name, group name, owner name, or any other field in an extended header record cannot be translated between the codeset in use for that extended header record and the character set of the current locale, pax shall write a diagnostic message to standard error, shall process the file as described for the $-\mathbf{o}$ invalid=option, and then shall continue processing with the next file.

## OUTPUT FILES

In read mode, the extracted output files shall be of the archived file type. In copy mode, the copied output files shall be the type of the file being copied. In either mode, existing files in the destination hierarchy shall be overwritten only when all permission ( $-\mathbf{p}$ ), modification time ( $-\mathbf{u}$ ), and invalid-value (-oinvalid=) tests allow it.

In write mode, the output file named by the -f option-argument shall be a file formatted according to one of the specifications in the EXTENDED DESCRIPTION section, or some other implementation-defined format.

## EXTENDED DESCRIPTION

## pax Interchange Format

A pax archive tape or file produced in the -xpax format shall contain a series of blocks. The physical layout of the archive shall be identical to the ustar format described in ustar Interchange Format (on page 721). Each file archived shall be represented by the following sequence:

- An optional header block with extended header records. This header block is of the form described in pax Header Block (on page 716), with a typeflag value of $\mathbf{x}$ or $\mathbf{g}$. The extended header records, described in pax Extended Header (on page 717), shall be included as the data for this header block.
- A header block that describes the file. Any fields in the preceding optional extended header shall override the associated fields in this header block for this file.
- Zero or more blocks that contain the contents of the file.

At the end of the archive file there shall be two 512-byte blocks filled with binary zeros, interpreted as an end-of-archive indicator.
A schematic of an example archive with global extended header records and two actual files is
shown in Figure 4-1 (on page 716). In the example, the second file in the archive has no extended header preceding it, presumably because it has no need for extended attributes.

| ustar Header [typeflag=g] |
| :--- |
| Global Extended Header Data |
| ustar Header [typeflag=x] |
| Extended Header Data |
| ustar Header [typeflag=0] |
| Data for File 1 |
| ustar Header [typeflag=0] |
| Data for File 2 |
| Block of binary zeros |
| Block of binary zeros |

File 1: Extended Header is included

File 2: No Extended Header is included

End of Archive Indicator

## pax Header Block

The pax header block shall be identical to the ustar header block described in ustar Interchange Format (on page 721), except that two additional typeflag values are defined:
x Represents extended header records for the following file in the archive (which shall have its own ustar header block). The format of these extended header records shall be as described in pax Extended Header (on page 717).
g Represents global extended header records for the following files in the archive. The format of these extended header records shall be as described in pax Extended Header (on page 717). Each value shall affect all subsequent files that do not override that value in their own extended header record and until another global extended header record is reached that provides another value for the same field. The typeflag $\mathbf{g}$ global headers should not be used with interchange media that could suffer partial data loss in transporting the archive.
For both of these types, the size field shall be the size of the extended header records in octets. The other fields in the header block are not meaningful to this version of the pax utility. However, if this archive is read by a pax utility conforming to the ISO POSIX-2: 1993 standard, the header block fields are used to create a regular file that contains the extended header records as data. Therefore, header block field values should be selected to provide reasonable file access to this regular file.

A further difference from the ustar header block is that data blocks for files of typeflag 1 (the digit one) (hard link) may be included, which means that the size field may be greater than zero. Archives created by pax -o linkdata shall include these data blocks with the hard links.

## pax Extended Header

A pax extended header contains values that are inappropriate for the ustar header block because of limitations in that format: fields requiring a character encoding other than that described in the ISO/IEC 646:1991 standard, fields representing file attributes not described in the ustar header, and fields whose format or length do not fit the requirements of the ustar header. The values in an extended header add attributes to the following file (or files; see the description of the typeflag $\mathbf{g}$ header block) or override values in the following header block(s), as indicated in the following list of keywords.
An extended header shall consist of one or more records, each constructed as follows:
"\%d \%s=\%s\n", <length>, <keyword>, <value>
The extended header records shall be encoded according to the ISO/IEC 10646-1:2000 standard UTF-8 encoding. The <length> field, <blank>, equals sign, and <newline> shown shall be limited to the portable character set, as encoded in UTF-8. The <keyword> fields can be any UTF-8 characters. The <length> field shall be the decimal length of the extended header record in octets, including the trailing <newline>. If there is a hdrcharset extended header in effect for a file, the value field for any gname, linkpath, path, and uname extended header records shall be encoded using the character set specified by the hdrcharset extended header record; otherwise, the value field shall be encoded using UTF-8. The value field for all other keywords specified by this standard shall be encoded using UTF-8.
The <keyword> field shall be one of the entries from the following list or a keyword provided as an implementation extension. Keywords consisting entirely of lowercase letters, digits, and periods are reserved for future standardization. A keyword shall not include an equals sign. (In the following list, the notations "file(s)" or "block(s)" is used to acknowledge that a keyword affects the following single file after a typeflag $\mathbf{x}$ extended header, but possibly multiple files after typeflag $\mathbf{g}$. Any requirements in the list for pax to include a record when in write or copy mode shall apply only when such a record has not already been provided through the use of the -o option. When used in copy mode, pax shall behave as if an archive had been created with applicable extended header records and then extracted.)
atime $\quad$ The file access time for the following file(s), equivalent to the value of the st_atime member of the stat structure for a file, as described by the stat() function. The access time shall be restored if the process has the appropriate privilege required to do so. The format of the <value> shall be as described in pax Extended Header File Times (on page 720).
charset The name of the character set used to encode the data in the following file(s). The entries in the following table are defined to refer to known standards; additional names may be agreed on between the originator and recipient.

| <value> | Formal Standard |
| :--- | :--- |
| ISO-IR $\Delta 646 \Delta 1990$ | ISO/IEC 646:1990 |
| ISO-IR $\Delta 8859 \Delta 1 \Delta 1998$ | ISO/IEC 8859-1:1998 |
| ISO-IR $\Delta 8859 \Delta 2 \Delta 1999$ | ISO/IEC 8859-2: 1999 |
| ISO-IR $\Delta 8859 \Delta 3 \Delta 1999$ | ISO/IEC 8859-3: 1999 |
| ISO-IR $\Delta 8859 \Delta 4 \Delta 1998$ | ISO/IEC 8859-4:1998 |
| ISO-IR $88859 \Delta 5 \Delta 1999$ | ISO/IEC 8859-5: 1999 |
| ISO-IR $\Delta 8859 \Delta 6 \Delta 1999$ | ISO/IEC 8859-6:1999 |
| ISO-IR $88859 \Delta 7 \Delta 1987$ | ISO/IEC 8859-7: 1987 |
| ISO-IR $\Delta 8859 \Delta 8 \Delta 1999$ | ISO/IEC 8859-8: 1999 |
| ISO-IR $\Delta 8859 \Delta 9 \Delta 1999$ | ISO/IEC 8859-9:1999 |
| ISO-IR $88859 \Delta 10 \Delta 1998$ | ISO/IEC 8859-10:1998 |
| ISO-IR $\Delta 8859 \Delta 13 \Delta 1998$ | ISO/IEC 8859-13:1998 |
| ISO-IR $\Delta 8859 \Delta 14 \Delta 1998$ | ISO/IEC 8859-14:1998 |
| ISO-IR $88859 \Delta 15 \Delta 1999$ | ISO/IEC 8859-15:1999 |
| ISO-IR $\Delta 10646 \Delta 2000$ | ISO/IEC 10646: 2000 |
| ISO-IR $\Delta 10646 \Delta 2000 \Delta U T F-8$ | ISO/IEC 10646, UTF-8 encoding |
| BINARY | None. |

The encoding is included in an extended header for information only; when pax is used as described in IEEE Std 1003.1-200x, it shall not translate the file data into any other encoding. The BINARY entry indicates unencoded binary data.
When used in write or copy mode, it is implementation-defined whether pax includes a charset extended header record for a file.
comment A series of characters used as a comment. All characters in the <value> field shall be ignored by pax.
gid The group ID of the group that owns the file, expressed as a decimal number using digits from the ISO/IEC 646:1991 standard. This record shall override the gid field in the following header block(s). When used in write or copy mode, pax shall include a gid extended header record for each file whose group ID is greater than 2097151 (octal 7777777).
gname The group of the file(s), formatted as a group name in the group database. This record shall override the gid and gname fields in the following header block(s), and any gid extended header record. When used in read, copy, or list mode, pax shall translate the name from the encoding in the header record to the character set appropriate for the group database on the receiving system. If any of the characters cannot be translated, and if neither the -oinvalid=UTF-8 option nor the -oinvalid=binary option is specified, the results are implementation-defined. When used in write or copy mode, pax shall include a gname extended header record for each file whose group name cannot be represented entirely with the letters and digits of the portable character set.
hdrcharset The name of the character set used to encode the value field of the gname, linkpath, path, and uname pax extended header records. The entries in the following table are defined to refer to known standards; additional names may be agreed between the originator and the recipient.

| <value> | Formal Standard |
| :--- | :--- |
| ISO-IRD10646 <br> BINARY | ISO/IEC 10646, UTF-8 encoding <br> None. |

If no hdrcharset extended header record is specified, the default character set used to encode all values in extended header records shall be the ISO/IEC 10646-1: 2000
standard UTF-8 encoding.
The BINARY entry indicates that all values recorded in extended headers for affected files are unencoded binary data from the underlying system.
linkpath The pathname of a link being created to another file, of any type, previously archived. This record shall override the linkname field in the following ustar header block(s). The following ustar header block shall determine the type of link created. If typeflag of the following header block is 1 , it shall be a hard link. If typeflag is 2 , it shall be a symbolic link and the linkpath value shall be the contents of the symbolic link. The pax utility shall translate the name of the link (contents of the symbolic link) from the encoding in the header to the character set appropriate for the local file system. When used in write or copy mode, pax shall include a linkpath extended header record for each link whose pathname cannot be represented entirely with the members of the portable character set other than NUL.
mtime The file modification time of the following file(s), equivalent to the value of the st_mtime member of the stat structure for a file, as described in the stat() function. This record shall override the mtime field in the following header block(s). The modification time shall be restored if the process has the appropriate privilege required to do so. The format of the <value> shall be as described in pax Extended Header File Times (on page 720).
path The pathname of the following file(s). This record shall override the name and prefix fields in the following header block(s). The pax utility shall translate the pathname of the file fr

If the <value> field is zero length, it shall delete any header block field, previously entered extended header value, or global extended header value of the same name.
If a keyword in an extended header record (or in a -o option-argument) overrides or deletes a corresponding field in the ustar header block, pax shall ignore the contents of that header block field.

Unlike the ustar header block fields, NULs shall not delimit <value>s; all characters within the <value> field shall be considered data for the field. None of the length limitations of the ustar header block fields in Table 4-13 shall apply to the extended header records.

## pax Extended Header Keyword Precedence

This section describes the precedence in which the various header records and fields and command line options are selected to apply to a file in the archive. When pax is used in read or list modes, it shall determine a file attribute in the following sequence:

1. If -odelete=keyword-prefix is used, the affected attributes shall be determined from step 7., if applicable, or ignored otherwise.
2. If -okeyword: = is used, the affected attributes shall be ignored.
3. If -okeyword:=value is used, the affected attribute shall be assigned the value.
4. If there is a typeflag $\mathbf{x}$ extended header record, the affected attribute shall be assigned the <value>. When extended header records conflict, the last one given in the header shall take precedence.
5. If -okeyword=value is used, the affected attribute shall be assigned the value.
6. If there is a typeflag $\mathbf{g}$ global extended header record, the affected attribute shall be assigned the <value>. When global extended header records conflict, the last one given in the global header shall take precedence.
7. Otherwise, the attribute shall be determined from the ustar header block.

## pax Extended Header File Times

The pax utility shall write an mtime record for each file in write or copy modes if the file's modification time cannot be represented exactly in the ustar header logical record described in ustar Interchange Format (on page 721). This can occur if the time is out of ustar range, or if the file system of the underlying implementation supports non-integer time granularities and the time is not an integer. All of these time records shall be formatted as a decimal representation of the time in seconds since the Epoch. If a period ( ${ }^{\prime} .^{\prime}$ ) decimal point character is present, the digits to the right of the point shall represent the units of a subsecond timing granularity, where the first digit is tenths of a second and each subsequent digit is a tenth of the previous digit. In read or copy mode, the pax utility shall truncate the time of a file to the greatest value that is not greater than the input header file time. In write or copy mode, the pax utility shall output a time exactly if it can be represented exactly as a decimal number, and otherwise shall generate only enough digits so that the same time shall be recovered if the file is extracted on a system whose underlying implementation supports the same time granularity.

## ustar Interchange Format

A ustar archive tape or file shall contain a series of logical records. Each logical record shall be a fixed-size logical record of 512 octets (see below). Although this format may be thought of as being stored on 9-track industry-standard 12.7 mm ( 0.5 in ) magnetic tape, other types of transportable media are not excluded. Each file archived shall be represented by a header logical record that describes the file, followed by zero or more logical records that give the contents of the file. At the end of the archive file there shall be two 512-octet logical records filled with binary zeros, interpreted as an end-of-archive indicator.
The logical records may be grouped for physical I/O operations, as described under the -bblocksize and -x ustar options. Each group of logical records may be written with a single operation equivalent to the write () function. On magnetic tape, the result of this write shall be a single tape physical block. The last physical block shall always be the full size, so logical records after the two zero logical records may contain undefined data.
The header logical record shall be structured as shown in the following table. All lengths and offsets are in decimal.

Table 4-13 ustar Header Block

| Field Name | Octet Offset | Length (in Octets) |
| :--- | :---: | :---: |
| name | 0 | 100 |
| mode | 100 | 8 |
| uid | 108 | 8 |
| gid | 116 | 8 |
| size | 124 | 12 |
| mime | 136 | 12 |
| chksum | 148 | 8 |
| typeflag | 156 | 1 |
| linkname | 157 | 100 |
| magic | 257 | 6 |
| version | 263 | 2 |
| uname | 265 | 32 |
| gname | 297 | 32 |
| devmajor | 329 | 8 |
| devminor | 337 | 8 |
| prefix | 345 | 155 |

All characters in the header logical record shall be represented in the coded character set of the ISO/IEC 646: 1991 standard. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside of slash and the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes.
However, the pax utility shall never create filenames on the local system that cannot be accessed via the procedures described in IEEE Std 1003.1-200x. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored. The pax utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.
Each field within the header logical record is contiguous; that is, there is no padding used. Each character on the archive medium shall be stored contiguously.

The fields magic, uname, and gname are character strings each terminated by a NUL character. The fields name, linkname, and prefix are NUL-terminated character strings except when all characters in the array contain non-NUL characters including the last character. The version field is two octets containing the characters " 00 " (zero-zero). The typeflag contains a single character. All other fields are leading zero-filled octal numbers using digits from the ISO/IEC 646: 1991 standard IRV. Each numeric field is terminated by one or more <space> or NUL characters.

The name and the prefix fields shall produce the pathname of the file. A new pathname shall be formed, if prefix is not an empty string (its first character is not NUL), by concatenating prefix (up to the first NUL character), a slash character, and name; otherwise, name is used alone. In either case, name is terminated at the first NUL character. If prefix begins with a NUL character, it shall be ignored. In this manner, pathnames of at most 256 characters can be supported. If a pathname does not fit in the space provided, pax shall notify the user of the error, and shall not store any part of the file-header or data-on the medium.
The linkname field, described below, shall not use the prefix to produce a pathname. As such, a linkname is limited to 100 characters. If the name does not fit in the space provided, pax shall notify the user of the error, and shall not attempt to store the link on the medium.
The mode field provides 12 bits encoded in the ISO/IEC 646:1991 standard octal digit representation. The encoded bits shall represent the following values:

Table 4-14 ustar mode Field

| Bit Value | IEEE Std 1003.1-200x Bit | Description |
| :---: | :--- | :--- |
| 04000 | S_ISUID | Set UID on execution. |
| 02000 | S_ISGID | Set GID on execution. |
| 01000 | <reserved $>$ | Reserved for future standardization. |
| 00400 | S_IRUSR | Read permission for file owner class. |
| 00200 | S_IWUSR | Write permission for file owner class. |
| 00100 | S_IXUSR | Execute/search permission for file owner class. |
| 00040 | S_IRGRP | Read permission for file group class. |
| 00020 | S_IWGRP | Write permission for file group class. |
| 00010 | S_IXGRP | Execute/search permission for file group class. |
| 00004 | S_IROTH | Read permission for file other class. |
| 00002 | S_IWOTH | Write permission for file other class. |
| 00001 | S_IXOTH | Execute/search permission for file other class. |

When appropriate privilege is required to set one of these mode bits, and the user restoring the files from the archive does not have the appropriate privilege, the mode bits for which the user does not have appropriate privilege shall be ignored. Some of the mode bits in the archive format are not mentioned elsewhere in this volume of IEEEStd 1003.1-200x. If the implementation does not support those bits, they may be ignored.
The uid and gid fields are the user and group ID of the owner and group of the file, respectively.
The size field is the size of the file in octets. If the typeflag field is set to specify a file to be of type 1 (a link) or 2 (a symbolic link), the size field shall be specified as zero. If the typeflag field is set to specify a file of type 5 (directory), the size field shall be interpreted as described under the definition of that record type. No data logical records are stored for types 1,2, or 5 . If the typeflag field is set to 3 (character special file), 4 (block special file), or 6 (FIFO), the meaning of the size field is unspecified by this volume of IEEE Std 1003.1-200x, and no data logical records shall be stored on the medium. Additionally, for type 6 , the size field shall be ignored when reading. If the typeflag field is set to any other value, the number of logical records written following the header shall be (size +511 )/512, ignoring any fraction in the result of the division.

The mtime field shall be the modification time of the file at the time it was archived. It is the

ISO/IEC 646: 1991 standard representation of the octal value of the modification time obtained from the stat () function.

The chksum field shall be the ISO/IEC 646: 1991 standard IRV representation of the octal value of the simple sum of all octets in the header logical record. Each octet in the header shall be treated as an unsigned value. These values shall be added to an unsigned integer, initialized to zero, the precision of which is not less than 17 bits. When calculating the checksum, the chksum field is treated as if it were all spaces.

The typeflag field specifies the type of file archived. If a particular implementation does not recognize the type, or the user does not have appropriate privilege to create that type, the file shall be extracted as if it were a regular file if the file type is defined to have a meaning for the size field that could cause data logical records to be written on the medium (see the previous description for size). If conversion to a regular file occurs, the pax utility shall produce an error indicating that the conversion took place. All of the typeflag fields shall be coded in the ISO/IEC 646: 1991 standard IRV:
0 Represents a regular file. For backwards-compatibility, a typeflag value of binary zero ( ${ }^{\prime} \backslash 0^{\prime}$ ) should be recognized as meaning a regular file when extracting files from the archive. Archives written with this version of the archive file format create regular files with a typeflag value of the ISO/IEC 646: 1991 standard IRV ' 0 '.

1 Represents a file linked to another file, of any type, previously archived. Such files are identified by having the same device and file serial numbers, and pathnames that refer to different directory entries. All such files shall be archived as linked files. The linkedto name is specified in the linkname field with a NUL-character terminator if it is less than 100 octets in length.
2 Represents a symbolic link. The contents of the symbolic link shall be stored in the linkname field.

3,4 Represent character special files and block special files respectively. In this case the devmajor and devminor fields shall contain information defining the device, the format of which is unspecified by this volume of IEEE Std 1003.1-200x. Implementations may map the device specifications to their own local specification or may ignore the entry.

5
Specifies a directory or subdirectory. On systems where disk allocation is performed on a directory basis, the size field shall contain the maximum number of octets (which may be rounded to the nearest disk block allocation unit) that the directory may hold. A size field of zero indicates no such limiting. Systems that do not support limiting in this manner should ignore the size field.
6 Specifies a FIFO special file. Note that the archiving of a FIFO file archives the existence of this file and not its contents.
7 Reserved to represent a file to which an implementation has associated some highperformance attribute. Implementations without such extensions should treat this file as a regular file (type 0 ).
$A-Z \quad$ The letters ' $A$ ' to ' $Z$ ', inclusive, are reserved for custom implementations. All other values are reserved for future versions of IEEE Std 1003.1-200x.

It is unspecified whether files with pathnames that refer to the same directory entry are archived as linked files or as separate files. If they are archived as linked files, this means that attempting to extract both pathnames from the resulting archive will always cause an error (unless the $-\mathbf{u}$ option is used) because the link cannot be created.
It is unspecified whether files with the same device and file serial numbers being appended to an archive are treated as linked files to members that were in the archive before the append.
Attempts to archive a socket using ustar interchange format shall produce a diagnostic message.

Handling of other file types is implementation-defined.
The magic field is the specification that this archive was output in this archive format. If this field contains ustar (the five characters from the ISO/IEC 646: 1991 standard IRV shown followed by NUL), the uname and gname fields shall contain the ISO/IEC 646:1991 standard IRV representation of the owner and group of the file, respectively (truncated to fit, if necessary). When the file is restored by a privileged, protection-preserving version of the utility, the user and group databases shall be scanned for these names. If found, the user and group IDs contained within these files shall be used rather than the values contained within the uid and gid fields.

## cpio Interchange Format

The octet-oriented cpio archive format shall be a series of entries, each comprising a header that describes the file, the name of the file, and then the contents of the file.
An archive may be recorded as a series of fixed-size blocks of octets. This blocking shall be used only to make physical I/O more efficient. The last group of blocks shall always be at the full size.

For the octet-oriented cpio archive format, the individual entry information shall be in the order indicated and described by the following table; see also the <cpio.h> header.

Table 4-15 Octet-Oriented cpio Archive Entry

| Header Field Name | Length (in Octets) | Interpreted as |
| :---: | :---: | :---: |
| c_magic | 6 | Octal number |
| c_dev | 6 | Octal number |
| c_ino | 6 | Octal number |
| C c_mode | 6 | Octal number |
| c_utid | 6 | Octal number |
| c_gid | 6 | Octal number |
| c_nlink | 6 | Octal number |
| c_rdev | 6 | Octal number |
| c_mtime |  | Octal number |
| c_namesize | 6 | Octal number |
| c.filesize | 11 | Octal number |
| Filename Field Name | Length | Interpreted as |
| c_name | c_namesize | Pathname string |
| File Data Field Name | Length | Interpreted as |
| c_filedata | c_filesize | Data |

## cpio Header

For each file in the archive, a header as defined previously shall be written. The information in the header fields is written as streams of the ISO/IEC 646: 1991 standard characters interpreted as octal numbers. The octal numbers shall be extended to the necessary length by appending the ISO/IEC 646: 1991 standard IRV zeros at the most-significant-digit end of the number; the result is written to the most-significant digit of the stream of octets first. The fields shall be interpreted as follows:
c_magic Identify the archive as being a transportable archive by containing the identifying value "070707".
> c_dev, c_ino Contains values that uniquely identify the file within the archive (that is, no files contain the same pair of $c_{-} d e v$ and $c_{-}$ino values unless they are links to the same file). The values shall be determined in an unspecified manner.
> c_mode Contains the file type and access permissions as defined in the following table.

Table 4-16 Values for cpio c_mode Field

| File Permissions Name | Value | Indicates |
| :--- | :---: | :--- |
| C_IRUSR | 000400 | Read by owner |
| C_IWUSR | 000200 | Write by owner |
| C_IXUSR | 000100 | Execute by owner |
| C_IRGRP | 000040 | Read by group |
| C_IWGRP | 000020 | Write by group |
| C_IXGRP | 000010 | Execute by group |
| C_IROTH | 000004 | Read by others |
| C_IWOTH | 000002 | Write by others |
| C_IXOTH | 000001 | Execute by others |
| C_ISUID | 004000 | Set uid |
| C_ISGID | 002000 | Set gid |
| C_ISVTX | 001000 | Reserved |
| File Type Name | Value | Indicates |
| C_ISDIR | 040000 | Directory |
| C_ISFIFO | 010000 | FIFO |
| C_ISREG | 0100000 | Regular file |
| C_ISLNK | 0120000 | Symboliclink |
| C_ISBLK | 060000 | Block special file |
| C_ISCHR | 020000 | Character special file |
| C_ISSOCK | 0140000 | Socket |
| C_ISCTG | 0110000 | Reserved |

Directories, FIFOs, symbolic links, and regular files shall be supported on a system conforming to this volume of IEEE Std 1003.1-200x; additional values defined previously are reserved for compatibility with existing systems. Additional file types may be supported; however, such files should not be written to archives intended to be transported to other systems.
c_uid Contains the user ID of the owner.
c_gid Contains the group ID of the group.
c_nlink Contains a number greater than or equal to the number of links in the archive referencing the file. If the $-\mathbf{a}$ option is used to append to a cpio archive, then the pax utility need not account for the files in the existing part of the archive when calculating the c_nlink values for the appended part of the archive, and need not alter the c_nlink values in the existing part of the archive if additional files with the same $c_{-} d e v$ and $c_{-}$ino values are appended to the archive.
c_rdev Contains implementation-defined information for character or block special files.
c_mtime Contains the latest time of modification of the file at the time the archive was created.
c_namesize Contains the length of the pathname, including the terminating NUL character.
c_filesize Contains the length in octets of the data section following the header structure.

## cpio Filename

The c_name field shall contain the pathname of the file. The length of this field in octets is the value of c_namesize.

If a filename is found on the medium that would create an invalid pathname, it is implementation-defined whether the data from the file is stored on the file hierarchy and under what name it is stored.

All characters shall be represented in the ISO/IEC 646:1991 standard IRV. For maximum portability between implementations, names should be selected from characters represented by the portable filename character set as octets with the most significant bit zero. If an implementation supports the use of characters outside the portable filename character set in names for files, users, and groups, one or more implementation-defined encodings of these characters shall be provided for interchange purposes. However, the pax utility shall never create filenames on the local system that cannot be accessed via the procedures described previously in this volume of IEEE Std 1003.1-200x. If a filename is found on the medium that would create an invalid filename, it is implementation-defined whether the data from the file is stored on the local file system and under what name it is stored. The pax utility may choose to ignore these files as long as it produces an error indicating that the file is being ignored.

## cpio File Data

Following c_name, there shall be c filesize octets of data. Interpretation of such data occurs in a manner dependent on the file. For regular files, the data shall consist of the contents of the file. For symblic links, the data shall consist of the contents of the symbolic link. If $c$ _filesize is zero, no data shall be contained in c_filedata.

When restoring from an archive:

- If the user does not have the appropriate privilege to create a file of the specified type, pax shall ignore the entry and write an error message to standard error.
- Only regular files and symbolic links have data to be restored. Presuming a regular file meets any selection criteria that might be imposed on the format-reading utility by the user, such data shall be restored.
- If a user does not have appropriate privilege to set a particular mode flag, the flag shall be ignored. Some of the mode flags in the archive format are not mentioned elsewhere in this volume of IEEE Std 1003.1-200x. If the implementation does not support those flags, they may be ignored.

## cpio Special Entries

FIFO special files, directories, and the trailer shall be recorded with c_filesize equal to zero. Symbolic links shall be recorded with $c$ _filesize equal to the length of the contents of the symbolic link. For other special files, c_filesize is unspecified by this volume of IEEE Std 1003.1-200x. The header for the next file entry in the archive shall be written directly after the last octet of the file entry preceding it. A header denoting the filename TRAILER!!! shall indicate the end of the archive; the contents of octets in the last block of the archive following such a header are undefined.

## EXIT STATUS

The following exit values shall be returned:
0 All files were processed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If

In read mode, implementations are permitted to overwrite files when the archive has multiple members with the same name. This may fail if permissions on the first version of the file do not permit it to be overwritten.
The cpio and ustar formats can only support files up to 8589934592 bytes $\left(8 * 2^{\wedge} 30\right)$ in size.
When archives containing binary header information are listed, the filenames printed may cause strange behavior on some terminals.

## EXAMPLES

The following command:
pax -w -f /dev/rmt/1m.
copies the contents of the current directory to tape drive 1, medium density (assuming historical System V device naming procedures-the historical BSD device name would be /dev/rmt9).
The following commands:

```
mkdir newdir
pax -rw olddir newdir
```

copy the olddir directory hierarchy to newdir.
pax -r -s ', ^//*usr//*,', -f a.pax
reads the archive a.pax, with all files rooted in /usr in the archive extracted relative to the current directory.

Using the option:
-o listopt $=$ "\%M \% (atime)T \%(size)D \%(name)s"
overrides the default output description in Standard Output and instead writes:
-rw-rw--- Jan 12 15:53 20031492 /usr/foo/bar
Using the options:
-o listopt $=$ '\%L\t\%(size) $D \backslash n \% .7^{\prime}$ \
-o listopt $=$ (name) $S \backslash n \%$ (atime) $T \backslash n \% T^{\prime}$
overrides the default output description in Standard Output and instead writes:
/usr/foo/bar $\rightarrow$ /tmp 1492
/usr/fo
Jan 12 15:53 1991
Jan 31 15:53 2003

## RATIONALE

The pax utility was new for the ISO POSIX-2: 1993 standard. It represents a peaceful compromise between advocates of the historical tar and cpio utilities.

A fundamental difference between cpio and tar was in the way directories were treated. The cpio utility did not treat directories differently from other files, and to select a directory and its contents required that each file in the hierarchy be explicitly specified. For tar, a directory matched every file in the file hierarchy it rooted.

The pax utility offers both interfaces; by default, directories map into the file hierarchy they root. The -d option causes pax to skip any file not explicitly referenced, as cpio historically did. The tar -style behavior was chosen as the default because it was believed that this was the more common usage and because tar is the more commonly available interface, as it was historically provided on both System V and BSD implementations.
The data interchange format specification in this volume of IEEE Std 1003.1-200x requires that
processes with "appropriate privileges" shall always restore the ownership and permissions of extracted files exactly as archived. If viewed from the historic equivalence between superuser and "appropriate privileges", there are two problems with this requirement. First, users running as superusers may unknowingly set dangerous permissions on extracted files. Second, it is needlessly limiting, in that superusers cannot extract files and own them as superuser unless the archive was created by the superuser. (It should be noted that restoration of ownerships and permissions for the superuser, by default, is historical practice in cpio, but not in tar.) In order to avoid these two problems, the pax specification has an additional "privilege" mechanism, the -p option. Only a pax invocation with the privileges needed, and which has the $-\mathbf{p}$ option set using the e specification character, has the "appropriate privilege" to restore full ownership and permission information.
Note also that this volume of IEEE Std 1003.1-200x requires that the file ownership and access permissions shall be set, on extraction, in the same fashion as the creat() function when provided with the mode stored in the archive. This means that the file creation mask of the user is applied to the file permissions.
Users should note that directories may be created by pax while extracting files with permissions that are different from those that existed at the time the archive was created. When extracting sensitive information into a directory hierarchy that no longer exists, users are encouraged to set their file creation mask appropriately to protect these files during extraction.

The table of contents output is written to standard output to facilitate pipeline processing.
An early proposal had hard links displaying for all pathnames. This was removed because it

significant performance advantages over historical implementations. The $\mathbf{- n}$ option in early proposals had three effects; the first was to cause special characters in patterns to not be treated specially. The second was to cause only the first file that matched a pattern to be extracted. The third was to cause pax to write a diagnostic message to standard error when no file was found matching a specified pattern. Only the second behavior is retained by this volume of IEEE Std 1003.1-200x, for many reasons. First, it is in general not acceptable for a single option to have multiple effects. Second, the ability to make pattern matching characters act as normal characters is useful for parts of pax other than file extraction. Third, a finer degree of control over the special characters is useful because users may wish to normalize only a single special character in a single filename. Fourth, given a more general escape mechanism, the previous behavior of the $-\mathbf{n}$ option can be easily obtained using the -s option or a sed script. Finally, writing a diagnostic message when a pattern specified by the user is unmatched by any file is useful behavior in all cases.

In this version, the $-\mathbf{n}$ was removed from the copy mode synopsis of pax; it is inapplicable because there are no pattern operands specified in this mode.
There is another method than pax for copying subtrees in IEEE Std 1003.1-200x described as part of the $c p$ utility. Both methods are historical practice: $c p$ provides a simpler, more intuitive interface, while pax offers a finer granularity of control. Each provides additional functionality to the other; in particular, pax maintains the hard-link structure of the hierarchy while $c p$ does not. It is the intention of the standard developers that the results be similar (using appropriate option combinations in both utilities). The results are not required to be identical; there seemed insufficient gain to applications to balance the difficulty of implementations having to guarantee that the results would be exactly identical.
A single archive may span more than one file. It is suggested that implementations provide informative messages to the user on standard error whenever the archive file is changed.
The -d option (do not create intermediate directories not listed in the archive) found in early proposals was originally provided as a complement to the historic -d option of cpio. It has been deleted.

The $-s$ option in early proposals specified a subset of the substitution command from the ed utility. As there was no reason for only a subset to be supported, the -s option is now compatible with the current ed specification. Since the delimiter can be any non-null character, the following usage with single spaces is valid:
pax -s " foo bar " ...
The $-\mathbf{t}$ description is worded so as to note that this may cause the access time update caused by some other activity (which occurs while the file is being read) to be overwritten.
The default behavior of pax with regard to file modification times is the same as historical implementations of tar. It is not the historical behavior of cpio.
Because the -i option uses /dev/tty, utilities without a controlling terminal are not able to use this option.

The -y option, found in early proposals, has been deleted because a line containing a single period for the $-\mathbf{i}$ option has equivalent functionality. The special lines for the $\mathbf{- i}$ option (a single period and the empty line) are historical practice in cpio.

In early drafts, a -echarmap option was included to increase portability of files between systems using different coded character sets. This option was omitted because it was apparent that consensus could not be formed for it. In this version, the use of UTF- 8 should be an adequate substitute.

The ISO POSIX-2: 1993 standard and ISO POSIX-1 standard requirements for pax, however, made it very difficult to create a single archive containing files created using extended characters
provided by different locales. This revision adds the hdrcharset keyword to make it possible to archive files in these cases without dropping files due to translation errors.
Translating filenames and other attributes from a locale's encoding to UTF-8 and then back again can lose information, as the resulting filename might not be byte-for-byte equivalent to the original. To avoid this problem, users can specify the -o hdrcharset=binary option, which will cause the resulting archive to use binary format for all names and attributes. Such archives are not portable among hosts that use different native encodings (e.g., EBCDIC versus ASCII-based encodings), but they will allow interchange among the vast majority of POSIX file systems in practical use. Also, the -o hdrcharset=binary option will cause pax in copy mode to behave more like other standard utilities such as $c p$.

If the values specified by the -o exthdr.name=value, $-\mathbf{o}$ globexthdr.name=value, or by \$TMPDIR (if -o globexthdr.name is not specified) require a character encoding other than that described in the ISO/IEC 646: 1991 standard, a path extended header record will have to be created for the file. If a hdrcharset extended header record is active for such headers, it will determine the codeset used for the value field in these extended path header records. These path extended header records always need to be created when writing an archive even if hdrcharset=binary has been specified and would contain the same (binary) data that appears in the ustar header record prefix and name fields. (In other words, an extended header path record is always required to be generated if the prefix or name fields contain non-ASCII characters even when hdrcharset=binary is also in effect for that file.)
The $-\mathbf{k}$ option was added to address international concerns about the dangers involved in the character set transformations of - (if the target character set were different from the source, the filenames might be transformed into names matching existing files) and also was made more general to protect files transferred between file systems with different \{NAME_MAX\} values (truncating a filename on a smaller system might also inadvertently overwrite existing files). As stated, it prevents any overwriting, even if the target file is older than the source. This version adds more granularity of options to solve this problem by introducing the -oinvalid=optionspecifically the UTF-8 and binary actions. (Note that an existing file is still subject to overwriting in this case. The $-\mathbf{k}$ option closes that loophole.)
Some of the file characteristics referenced in this volume of IEEE Std 1003.1-200x might not be supported by some archive formats. For example, neither the tar nor cpio formats contain the file access time. For this reason, the e specification character has been provided, intended to cause all file characteristics specified in the archive to be retained.

It is required that extracted directories, by default, have their access and modification times and permissions set to the values specified in the archive. This has obvious problems in that the directories are almost certainly modified after being extracted and that directory permissions may not permit file creation. One possible solution is to create directories with the mode specified in the archive, as modified by the umask of the user, with sufficient permissions to allow file creation. After all files have been extracted, pax would then reset the access and modification times and permissions as necessary.
The list-mode formatting description borrows heavily from the one defined by the printf utility. However, since there is no separate operand list to get conversion arguments, the format was extended to allow specifying the name of the conversion argument as part of the conversion specification.

The T conversion specifier allows time fields to be displayed in any of the date formats. Unlike the ls utility, pax does not adjust the format when the date is less than six months in the past. This makes parsing the output more predictable.
The D conversion specifier handles the ability to display the major/minor or file size, as with $l s$, by using \%-8 (size) D.
The $L$ conversion specifier handles the $l s$ display for symbolic links.

Conversion specifiers were added to generate existing known types used for $l s$.

## pax Interchange Format

The new POSIX data interchange format was developed primarily to satisfy international concerns that the ustar and cpio formats did not provide for file, user, and group names encoded in characters outside a subset of the ISO/IEC 646:1991 standard. The standard developers realized that this new POSIX data interchange format should be very extensible because there were other requirements they foresaw in the near future:

- Support international character encodings and locale information
- Support security information (ACLs, and so on)
- Support future file types, such as realtime or contiguous files
- Include data areas for implementation use
- Support systems with words larger than 32 bits and timers with subsecond granularity

The following were not goals for this format because these are better handled by separate utilities or are inappropriate for a portable format:

- Encryption
- Compression
- Data translation between locales and codesets
- inode storage

The format chosen to support the goals is an extension of the ustar format. Of the two formats previously available, only the ustar format was selected for extensions because:

- It was easier to extend in an upwards-compatible way. It offered version flags and header block type fields with room for future standardization. The cpio format, while possessing a more flexible file naming methodology, could not be extended without breaking some theoretical implementation or using a dummy filename that could be a legitimate filename.
- Industry experience since the original "tar wars" fought in developing the ISO POSIX-1 standard has clearly been in favor of the ustar format, which is generally the default output format selected forpax implementations on new systems.
The new format was designed with one additional goal in mind: reasonable behavior when an older tar or pax utility happened to read an archive. Since the POSIX.1-1990 standard mandated that a "format-reading utility" had to treat unrecognized typeflag values as regular files, this allowed the format to include all the extended information in a pseudo-regular file that preceded each real file. An option is given that allows the archive creator to set up reasonable names for these files on the older systems. Also, the normative text suggests that reasonable file access values be used for this ustar header block. Making these header files inaccessible for convenient reading and deleting would not be reasonable. File permissions of 600 or 700 are suggested.

The ustar typeflag field was used to accommodate the additional functionality of the new format rather than magic or version because the POSIX.1-1990 standard (and, by reference, the previous version of pax), mandated the behavior of the format-reading utility when it encountered an unknown typeflag, but was silent about the other two fields.
Early proposals of the first revision to IEEE Std 1003.1-200x contained a proposed archive format that was based on compatibility with the standard for tape files (ISO 1001, similar to the format used historically on many mainframes and minicomputers). This format was overly complex and required considerable overhead in volume and header records. Furthermore, the standard developers felt that it would not be acceptable to the community of POSIX developers, so it was
later changed to be a format more closely related to historical practice on POSIX systems.
The prefix and name split of pathnames in ustar was replaced by the single path extended header record for simplicity.
The concept of a global extended header (typeflag $\mathbf{g}$ ) was controversial. If this were applied to an archive being recorded on magnetic tape, a few unreadable blocks at the beginning of the tape could be a serious problem; a utility attempting to extract as many files as possible from a damaged archive could lose a large percentage of file header information in this case. However, if the archive were on a reliable medium, such as a CD-ROM, the global extended header offers considerable potential size reductions by eliminating redundant information. Thus, the text warns against using the global method for unreliable media and provides a method for implanting global information in the extended header for each file, rather than in the typeflag $\mathbf{g}$ records.

No facility for data translation or filtering on a per-file basis is included because the standard developers could not invent an interface that would allow this in an efficient manner. If a filter, such as encryption or compression, is to be applied to all the files, it is more efficient to apply the filter to the entire archive as a single file. The standard developers considered interfaces that would invoke a shell script for each file going into or out of the archive, but the system overhead in this approach was considered to be too high.

One such approach would be to have filter= records that give a pathname for an executable. When the program is invoked, the file and archive would be open for standard input/output and all the header fields would be available as environment variables or command-line arguments. The standard developers did discuss such schemes, but they were omitted from IEEE Std 1003.1-200x due to concerns about excessive overhead. Also, the program itself would need to be in the archive if it were to be used portably.
There is currently no portable means of identifying the character set(s) used for a file in the file system. Therefore, pax has not been given a mechanism to generate charset records automatically. The only portable means of doing this is for the user to write the archive using the -ocharset=string command line option. This assumes that all of the files in the archive use the same encoding. The "implementation-defined" text is included to allow for a system that can identify the encodings used for each of its files.

The table of standards that accompanies the charset record description is acknowledged to be very limited. Only a limited number of character set standards is reasonable for maximal interchange. Any character set is, of course, possible by prior agreement. It was suggested that EBCDIC be listed, but it was omitted because it is not defined by a formal standard. Formal standards, and then only those with reasonably large followings, can be included here, simply as a matter of practicality. The <value>s represent names of officially registered character sets in the format required by the ISO 2375: 1985 standard.
The normal comma or <blank>-separated list rules are not followed in the case of keyword options to allow ease of argument parsing for getopts.
Further information on character encodings is in pax Archive Character Set Encoding/Decoding (on page 735).

The standard developers have reserved keyword name space for vendor extensions. It is suggested that the format to be used is:

VENDOR. keyword
where $V E N D O R$ is the name of the vendor or organization in all uppercase letters. It is further suggested that the keyword following the period be named differently than any of the standard keywords so that it could be used for future standardization, if appropriate, by omitting the $V E N D O R$ prefix.

The <length> field in the extended header record was included to make it simpler to step through the records, even if a record contains an unknown format (to a particular pax) with complex interactions of special characters. It also provides a minor integrity checkpoint within the records to aid a program attempting to recover files from a damaged archive.

There are no extended header versions of the devmajor and devminor fields because the unspecified format ustar header field should be sufficient. If they are not, vendor-specific extended keywords (such as VENDOR.devmajor) should be used.

Device and $i$-number labeling of files was not adopted from cpio; files are interchanged strictly on a symbolic name basis, as in ustar.
Just as with the ustar format descriptions, the new format makes no special arrangements for multi-volume archives. Each of the pax archive types is assumed to be inside a single POSIX file and splitting that file over multiple volumes (diskettes, tape cartridges, and so on), processing their labels, and mounting each in the proper sequence are considered to be implementation details that cannot be described portably.
The pax format is intended for interchange, not only for backup on a single (family of) systems. It is not as densely packed as might be possible for backup:

- It contains information as coded characters that could be coded in binary.
- It identifies extended records with name fields that could be omitted in favor of a fixedfield layout.
- It translates names into a portable character set and identifies locale-related information, both of which are probably unnecessary for backup.
The requirements on restoring from an archive are slightly different from the historical wording, allowing for non-monolithic privilege to bring forward as much as possible. In particular, attributes such as "high performance file" might be broadly but not universally granted while set-user-ID or chown() might be much more restricted. There is no implication in IEEE Std 1003.1-200x that the security information be honored after it is restored to the file hierarchy, in spite of what might be improperly inferred by the silence on that topic. That is a topic for another standard.

Links are recorded in the fashion described here because a link can be to any file type. It is desirable in general to be able to restore part of an archive selectively and restore all of those files completely. If the data is not associated with each link, it is not possible to do this. However, the data associated with a file can be large, and when selective restoration is not needed, this can be a significant burden. The archive is structured so that files that have no associated data can always be restored by the name of any link name of any link, and the user may choose whether data is recorded with each instance of a file that contains data. The format permits mixing of both types of links in a single archive; this can be done for special needs, and pax is expected to interpret such archives on input properly, despite the fact that there is no pax option that would force this mixed case on output. (When -o linkdata is used, the output must contain the duplicate data, but the implementation is free to include it or omit it when -o linkdata is not used.)

The time values are included as extended header records for those implementations needing more than the eleven octal digits allowed by the ustar format. Portable file timestamps cannot be negative. If pax encounters a file with a negative timestamp in copy or write mode, it can reject the file, substitute a non-negative timestamp, or generate a non-portable timestamp with a leading ' $\mathbf{~ ' ~}^{\prime}$. Even though some implementations can support finer file-time granularities than seconds, the normative text requires support only for seconds since the Epoch because the ISO POSIX-1 standard states them that way. The ustar format includes only mtime; the new format adds atime and ctime for symmetry. The atime access time restored to the file system will be affected by the $-\mathbf{p}$ a and $-\mathbf{p} \mathbf{e}$ options. The ctime creation time (actually inode modification
time) is described with "appropriate privilege" so that it can be ignored when writing to the file system. POSIX does not provide a portable means to change file creation time. Nothing is intended to prevent a non-portable implementation of pax from restoring the value.
The gid, size, and uid extended header records were included to allow expansion beyond the sizes specified in the regular tar header. New file system architectures are emerging that will exhaust the 12-digit size field. There are probably not many systems requiring more than 8 digits for user and group IDs, but the extended header values were included for completeness, allowing overrides for all of the decimal values in the tar header.
The standard developers intended to describe the effective results of pax with regard to file ownerships and permissions; implementations are not restricted in timing or sequencing the restoration of such, provided the results are as specified.
Much of the text describing the extended headers refers to use in "write or copy modes". The copy mode references are due to the normative text: "The effect of the copy shall be as if the copied files were written to an archive file and then subsequently extracted ...". There is certainly no way to test whether pax is actually generating the extended headers in copy mode, but the effects must be as if it had.

## pax Archive Character Set Encoding/Decoding

There is a need to exchange archives of files between systems of different native codesets. Filenames, group names, and user names must be preserved to the fullest extent possible when an archive is read on the receiving platform. Translation of the contents of files is not within the scope of the pax utility.
There will also be the need to represent characters that are not available on the receiving platform. These unsupported characters cannot be automatically folded to the local set of characters due to the chance of collisions. This could result in overwriting previous extracted files from the archive or pre-existing files on the system.
For these reasons, the codeset used to represent characters within the extended header records of the pax archive must be sufficiently rich to handle all commonly used character sets. The fields requiring translation include, at a minimum, filenames, user names, group names, and link pathnames. Implementations may wish to have localized extended keywords that use nonportable characters.

The standard developers considered the following options:

- The archive creator specifies the well-defined name of the source codeset. The receiver must then recognize the codeset name and perform the appropriate translations to the destination codeset.
- The archive creator includes within the archive the character mapping table for the source codeset used to encode extended header records. The receiver must then read the character mapping table and perform the appropriate translations to the destination codeset.
- The archive creator translates the extended header records in the source codeset into a canonical form. The receiver must then perform the appropriate translations to the destination codeset.

The approach that incorporates the name of the source codeset poses the problem of codeset name registration, and makes the archive useless to pax archive decoders that do not recognize that codeset.
Because parts of an archive may be corrupted, the standard developers felt that including the character map of the source codeset was too fragile. The loss of this one key component could result in making the entire archive useless. (The difference between this and the global extended
header decision was that the latter has a workaround-duplicating extended header records on unreliable media-but this would be too burdensome for large character set maps.)
Both of the above approaches also put an undue burden on the pax archive receiver to handle the cross-product of all source and destination codesets.
To simplify the translation from the source codeset to the canonical form and from the canonical form to the destination codeset, the standard developers decided that the internal representation should be a stateless encoding. A stateless encoding is one where each codepoint has the same meaning, without regard to the decoder being in a specific state. An example of a stateful encoding would be the Japanese Shift-JIS; an example of a stateless encoding would be the ISO/IEC 646: 1991 standard (equivalent to 7-bit ASCII).
For these reasons, the standard developers decided to adopt a canonical format for the representation of file information strings. The obvious, well-endorsed candidate is the ISO/IEC 10646-1: 2000 standard (based in part on Unicode), which can be used to represent the characters of virtually all standardized character sets. The standard developers initially agreed upon using UCS2 (16-bit Unicode) as the internal representation. This repertoire of characters provides a sufficiently rich set to represent all commonly-used codesets.
However, the standard developers found that the 16 -bit Unicode representation had some problems. It forced the issue of standardizing byte ordering. The 2-byte length of each character made the extended header records twice as long for the case of strings coded entirely from historical 7-bit ASCII. For these reasons, the standard developers chose the UTF-8 defined in the ISO/IEC 10646-1:2000 standard. This multi-byte representation encodes UCS2 or UCS4 characters reliably and deterministically, eliminating the need for a canonical byte ordering. In addition, NUL octets and other characters possibly confusing to POSIX file systems do not appear, except to represent themselves. It was realized that certain national codesets take up more space after the encoding, due to their placement within the UCS range; it was felt that the usefulness of the encoding of the names outweighs the disadvantage of size increase for file, user, and group names.
The encoding of UTF-8 is as follows:

```
UCS4 Hex Encoding UTF-8 Binary Encoding
00000000-0000007F 0xxxxxxx
00000080-000007FF 110xxxxx 10xxxxxx
00000800-0000FFFF 1110xxxx 10xxxxxx 10xxxxxx
00010000-001FFFFFF 11110xx% 10xxxxxx 10xxxxxx 10xxxxxx
00200000-03FFFFFF 111110xx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
04000000-7FFFFFFF 1111110x 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx 10xxxxxx
```

where each ' x ' represents a bit value from the character being translated.

## ustar Interchange Format

The description of the ustar format reflects numerous enhancements over pre-1988 versions of the historical tar utility. The goal of these changes was not only to provide the functional enhancements desired, but also to retain compatibility between new and old versions. This compatibility has been retained. Archives written using the old archive format are compatible with the new format.

Implementors should be aware that the previous file format did not include a mechanism to archive directory type files. For this reason, the convention of using a filename ending with slash was adopted to specify a directory on the archive.
The total size of the name and prefix fields have been set to meet the minimum requirements for \{PATH_MAX\}. If a pathname will fit within the name field, it is recommended that the pathname be stored there without the use of the prefix field. Although the name field is known to be too
small to contain $\{$ PATH_MAX $\}$ characters, the value was not changed in this version of the archive file format to retain backwards-compatibility, and instead the prefix was introduced. Also, because of the earlier version of the format, there is no way to remove the restriction on the linkname field being limited in size to just that of the name field.

The size field is required to be meaningful in all implementation extensions, although it could be zero. This is required so that the data blocks can always be properly counted.

It is suggested that if device special files need to be represented that cannot be represented in the standard format, that one of the extension types (A-Z) be used, and that the additional information for the special file be represented as data and be reflected in the size field.

Attempting to restore a special file type, where it is converted to ordinary data and conflicts with an existing filename, need not be specially detected by the utility. If run as an ordinary user, pax should not be able to overwrite the entries in, for example, /dev in any case (whether the file is converted to another type or not). If run as a privileged user, it should be able to do so, and it would be considered a bug if it did not. The same is true of ordinary data files and similarly named special files; it is impossible to anticipate the needs of the user (who could really intend to overwrite the file), so the behavior should be predictable (and thus regular) and rely on the protection system as required.

The value 7 in the typeflag field is intended to define how contiguous files can be stored in a ustar archive. IEEE Std 1003.1-200x does not require the contiguous file extension, but does define a standard way of archiving such files so that all conforming systems can interpret these file types in a meaningful and consistent manner. On a system that does not support extended file types, the pax utility should do the best it can with the file and go on to the next.

The file protection modes are those conventionally used by the $l s$ utility. This is extended beyond the usage in the ISO POSIX-2 standard to support the "shared text" or "sticky" bit. It is intended that the conformance document should not document anything beyond the existence of and support of such a mode. Further extensions are expected to these bits, particularly with overloading the set-user-ID and set-group-ID flags.

## cpio Interchange Format

The reference to appropriate privilege in the cpio format refers to an error on standard output; the ustar format does not make comparable statements.

The model for this format was the historical System V cpio-c data interchange format. This model documents the portable version of the cpio format and not the binary version. It has the flexibility to transfer data of any type described within IEEE Std 1003.1-200x, yet is extensible to transfer data types specific to extensions beyond IEEE Std 1003.1-200x (for example, contiguous files). Because it describes existing practice, there is no question of maintaining upwardscompatibility.

## cpio Header

There has been some concern that the size of the $c_{-}$ino field of the header is too small to handle those systems that have very large inode numbers. However, the $c_{-}$ino field in the header is used strictly as a hard-link resolution mechanism for archives. It is not necessarily the same value as the inode number of the file in the location from which that file is extracted.

The name c_magic is based on historical usage.

## cpio Filename

For most historical implementations of the cpio utility, $\left\{\mathrm{PATH} \_\mathrm{MAX}\right\}$ octets can be used to describe the pathname without the addition of any other header fields (the NUL character would be included in this count). \{PATH_MAX\} is the minimum value for pathname size, documented as 256 bytes. However, an implementation may use $c_{-}$namesize to determine the exact length of the pathname. With the current description of the <cpio.h> header, this pathname size can be as large as a number that is described in six octal digits.

Two values are documented under the c_mode field values to provide for extensibility for known file types:

0110000 Reserved for contiguous files. The implementation may treat the rest of the information for this archive like a regular file. If this file type is undefined, the implementation may create the file as a regular file.
This provides for extensibility of the cpio format while allowing for the ability to read old archives. Files of an unknown type may be read as "regular files" on some implementations. On a system that does not support extended file types, the pax utility should do the best it can with the file and go on to the next.

## FUTURE DIRECTIONS

## None.

## CHANGE HISTORY

First released in Issue 4.
Issue 5
A note is added to the APPLICATION USAGE indicating that the cpio and tar formats can only support files up to 8 gigabytes in size.

## Issue 6

The pax utility is aligned with the IEEE P1003.2b draft standard:

- Support has been added for symbolic links in theoptions and interchange formats.
- A new format has been devised, based on extensions to ustar.
- References to the "extended" tar and cpio formats derived from the POSIX.1-1990 standard have been changed to remove the "extended" adjective because this could cause confusion with the extended tar header added in this revision. (All references to tar are actually to ustar.)
The $T Z$ entry is added to the ENVIRONMENT VARIABLES section.
IEEE PASC Interpretation 1003.2 \#168 is applied, clarifying that $m k d i r()$ and $m k f i f o()$ calls can ignore an [EEXIST] error when extracting an archive.

IEEE PASC Interpretation 1003.2 \#180 is applied, clarifying how extracted files are created when in read mode.

IEEE PASC Interpretation 1003.2 \#181 is applied, clarifying the description of the $-\mathbf{t}$ option.
IEEE PASC Interpretation 1003.2 \#195 is applied.
IEEE PASC Interpretation 1003.2 \#206 is applied, clarifying the handling of links for the $\mathbf{- H},-\mathbf{L}$, and - 1 options.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/35 is applied, adding the process ID of
the pax process into certain fields. This change provides a method for the implementation to ensure that different instances of pax extracting a file named /a/b/foo will not collide when processing the extended header information associated with foo.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/36 is applied, changing $-\mathbf{x} \mathbf{B}$ to $-\mathbf{x}$ pax in the OPTIONS section.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/20 is applied, updating the SYNOPSIS to be consistent with the normative text.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/21 is applied, updating the DESCRIPTION to describe the behavior when files to be linked are symbolic links and the system is not capable of making hard links to symbolic links.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/22 is applied, updating the OPTIONS section to describe the behavior for how multiple -odelete=pattern options are to be handled.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/23 is applied, updating the write option within the OPTIONS section.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/24 is applied, adding a paragraph into the OPTIONS section that states that specifying more than one of the mutually-exclusive options $(-\mathbf{H}$ and $-\mathbf{L})$ is not considered an error and that the last option specified will determine the behavior of the utility.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/25 is applied, removing the ctime paragraph within the EXTENDED DESCRIPTION. There is a contradiction in the definition of the ctime keyword for the pax extended header, in that the st_ctime member of the stat structure does not refer to a file creation time. No field in the standard stat structure from <sys/stat.h> includes a file creation time.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/26 is applied, making it clear that typeflag 1 (ustar Interchange Format) applies not only to files that are hard-linked, but also to files that are aliased via symlinks.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/27 is applied, clarifying the cpio c_nlink field.

## Issue 7

SD5-XCU-ERN-2 is applied, making - $\mathbf{c}$ and $-\mathbf{n}$ mutually-exclusive in the SYNOPSIS.
SD5-XCU-ERN-3 is applied, revising the default behavior of $-\mathbf{H}$ and $-\mathbf{L}$.
SD5-XCU-ERN-5, SD5-XCU-ERN-6, SD5-XCU-ERN-7, SD5-XCU-ERN-60 are applied.
Austin Group Interpretations 1003.1-2001 \#011, \#036, \#086, and \#109 are applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
pr — print files

## SYNOPSIS

pr [+page] [-column] [-adFmrt] [-e[char][gap]] [-h header] [-i[char][gap]]
XSI [-l lines] [-n[char][width]] [-o offset] [-s[char]] [-w width] [-fp] [file...]

## DESCRIPTION

The $p r$ utility is a printing and pagination filter. If multiple input files are specified, each shall be read, formatted, and written to standard output. By default, the input shall be separated into 66-line pages, each with:

- A 5-line header that includes the page number, date, time, and the pathname of the file
- A 5-line trailer consisting of blank lines

If standard output is associated with a terminal, diagnostic messages shall be deferred until the $p r$ utility has completed processing.
When options specifying multi-column output are specified, output text columns shall be of equal width; input lines that do not fit into a text column shall be truncated. By default, text columns shall be separated with at least one <blank>.

## OPTIONS

The $p r$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x , Section 12.2, Utility Syntax Guidelines, except that: the page option has a ' + ' delimiter; page and column can be multi-digit numbers; some of the option-arguments are optional; and some of the optionarguments cannot be specified as separate arguments from the preceding option letter. In particular, the -s option does not allow the option letter to be separated from its argument, and the options $-\mathbf{e},-\mathbf{i}$, and $-\mathbf{n}$ require that both arguments, if present, not be separated from the option letter.

The following options shall be supported. In the following option descriptions, column, lines, offset, page, and width are positive decimal integers; gap is a non-negative decimal integer.

$$
\text { +page } \quad \text { Begin output at page number page of the formatted input. }
$$

-column Produce multi-column output that is arranged in column columns (the default shall be 1 ) and is written down each column in the order in which the text is received from the input file. This option should not be used with $-\mathbf{m}$. The options $-\mathbf{e}$ and $-\mathbf{i}$ shall be assumed for multiple text-column output. Whether or not text columns are produced with identical vertical lengths is unspecified, but a text column shall never exceed the length of the page (see the $-\mathbf{l}$ option). When used with $-\mathbf{t}$, use the minimum number of lines to write the output.
-a Modify the effect of the -column option so that the columns are filled across the page in a round-robin order (for example, when column is 2, the first input line heads column 1, the second heads column 2 , the third is the second line in column 1 , and so on).
-d Produce output that is double-spaced; append an extra <newline> following every <newline> found in the input.
-e[char][gap]
Expand each input <tab> to the next greater column position specified by the formula $n^{*}$ gap +1 , where $n$ is an integer $>0$. If gap is zero or is omitted, it shall default to 8 . All <tab>s in the input shall be expanded into the appropriate number
of <space>s. If any non-digit character, char, is specified, it shall be used as the input <tab>. If the first character of the -e option-argument is a digit, the entire option-argument shall be assumed to be gap.
XSI

Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline>s. Pause before beginning the first page if the standard output is associated with a terminal.

Use a <form-feed> for new pages, instead of the default behavior that uses a sequence of <newline>s.

Use the string header to replace the contents of the file operand in the page header.
In output, replace <space>s with <tab>s wherever one or more adjacent <space>s reach column positions $g a p+1,2^{*}$ gap $+1,3^{*}$ gap +1 , and so on. If gap is zero or is omitted, default tab settings at every eighth column position shall be assumed. If any non-digit character, char, is specified, it shall be used as the output <tab>. If the first character of the -i option-argument is a digit, the entire option-argument shall be assumed to be gap.
Override the 66 -line default and reset the page length to lines. If lines is not greater than the sum of both the header and trailer depths (in lines), the $p r$ utility shall suppress both the header and trailer, as if the $-\mathbf{t}$ option were in effect.
Merge files. Standard output shall be formatted so the $p r$ utility writes one line from each file specified by a file operand, side by side into text columns of equal fixed widths, in terms of the number of column positions. Implementations shall support merging of at least nine file operands.
$-\mathbf{n}[$ char $][$ width $]$
Provide width-digit line numbering (default for width shall be 5). The number shall occupy the first width column positions of each text column of default output or each line of -m output. If char (any non-digit character) is given, it shall be appended to the line number to separate it from whatever follows (default for char is a <tab>).
-o offset Each line of output shall be preceded by offset <space>s. If the -o option is not specified, the default offset shall be zero. The space taken is in addition to the output line width (see the -w option below).
$-\mathbf{p} \quad$ Pause before beginning each page if the standard output is directed to a terminal ( $p r$ shall write an <alert> to standard error and wait for a <carriage-return> to be read on $/ \mathrm{dev} / \mathrm{tty}$ ).
-r Write no diagnostic reports on failure to open files.
$-s[$ char $] \quad$ Separate text columns by the single character char instead of by the appropriate number of <space>s (default for char shall be <tab>).
-t Write neither the five-line identifying header nor the five-line trailer usually supplied for each page. Quit writing after the last line of each file without spacing to the end of the page.
-w width Set the width of the line to width column positions for multiple text-column output only. If the $-\mathbf{w}$ option is not specified and the $-\mathbf{s}$ option is not specified, the default width shall be 72 . If the $-\mathbf{w}$ option is not specified and the $-\mathbf{s}$ option is specified, the default width shall be 512 .
For single column output, input lines shall not be truncated.

## OPERANDS

The following operand shall be supported:
file A pathname of a file to be written. If no file operands are specified, or if a file operand is ' - ', the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified, or if a file operand is ' ${ }^{\prime}$. See the INPUT FILES section.

## INPUT FILES

The input files shall be text files.
The file /dev/tty shall be used to read responses required by the -p option.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of pr :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as printable (character class print). Non-printable characters are still written to standard output, but are not counted for the purpose for column-width and line-length calculations.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_TIME Determine the format of the date and time for use in writing header lines.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TZ
Determine the timezone used to calculate date and time strings written in header lines. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

If $p r$ receives an interrupt while writing to a terminal, it shall flush all accumulated error messages to the screen before terminating.

## STDOUT

The $p r$ utility output shall be a paginated version of the original file (or files). This pagination shall be accomplished using either <form-feed>s or a sequence of <newline>s, as controlled by
xsi the $-\mathbf{F}$ or $-\mathbf{f}$ option. Page headers shall be generated unless the $-\mathbf{t}$ option is specified. The page headers shall be of the form:
"\n\n\%s \%s Page \%d\n\n\n", <output of date>, <file>, <page number>
In the POSIX locale, the <output of date> field, representing the date and time of last modification of the input file (or the current date and time if the input file is standard input), shall be equivalent to the output of the following command as it would appear if executed at the given time:

```
date "+%b %e %H:%M %Y"
```

without the trailing <newline>, if the page being written is from standard input. If the page
being written is not from standard input, in the POSIX locale, the same format shall be used, but the time used shall be the modification time of the file corresponding to file instead of the current time. When the LC_TIME locale category is not set to the POSIX locale, a different format and order of presentation of this field may be used.

If the standard input is used instead of a file operand, the <file> field shall be replaced by a null string.

If the $-\mathbf{h}$ option is specified, the $<$ file $>$ field shall be replaced by the header argument.

## STDERR

The standard error shall be used for diagnostic messages and for alerting the terminal when $-\mathbf{p}$ is specified.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

A conforming application must protect its first operand, if it starts with a plus sign, by preceding it with the "--" argument that denotes the end of the options. For example, $p r+x$ could be interpreted as an invalid page number or a file operand.

## EXAMPLES

1. Print a numbered list of all files in the current directory:

Is -a $\mid$ pr -n -h "Files in $\$(p w d)$."
2. Print file1 and file2 as a double-spaced, three-column listing headed by "file list":
pr -3d -h "file list" file1 file2
3. Write file1 on file2, expanding tabs to columns $10,19,28, \ldots$ :
pr -e9 -t <file1 >file2

## RATIONALE

This utility is one of those that does not follow the Utility Syntax Guidelines because of its historical origins. The standard developers could have added new options that obeyed the guidelines (and marked the old options obsolescent) or devised an entirely new utility; there are examples of both actions in this volume of IEEE Std 1003.1-200x. Because of its widespread use by historical applications, the standard developers decided to exempt this version of $p r$ from many of the guidelines.

Implementations are required to accept option-arguments to the $-\mathbf{h}, \mathbf{l},-\mathbf{0}$, and $-\mathbf{w}$ options whether presented as part of the same argument or as a separate argument to $p r$, as suggested by the Utility Syntax Guidelines. The -n and -s options, however, are specified as in historical practice because they are frequently specified without their optional arguments. If a <blank> were allowed before the option-argument in these cases, a file operand could mistakenly be interpreted as an option-argument in historical applications.

The text about the minimum number of lines in multi-column output was included to ensure that a best effort is made in balancing the length of the columns. There are known historical implementations in which, for example, 60 -line files are listed by $p r-2$ as one column of 56 lines and a second of 4 . Although this is not a problem when a full page with headers and trailers is produced, it would be relatively useless when used with $-\mathbf{t}$.

Historical implementations of the $p r$ utility have differed in the action taken for the $-\mathbf{f}$ option. BSD uses it as described here for the $-F$ option; System V uses it to change trailing <newline>s on each page to a <form-feed> and, if standard output is a TTY device, sends an <alert> to standard error and reads a line from /dev/tty before the first page. There were strong arguments from both sides of this issue concerning historical practice and as a result the $-\mathbf{F}$ option was added. XSI-conformant systems support the System V historical actions for the $-\mathbf{f}$ option.
The <output of date> field in the -1 format is specified only for the POSIX locale. As noted, the format can be different in other locales. No mechanism for defining this is present in this volume of IEEE Std 1003.1-200x, as the appropriate vehicle is a message catalog; that is, the format should be specified as a "message".

## FUTURE DIRECTIONS

None.
SEE ALSO
expand, lp

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The $-\mathbf{p}$ option is added.

The normative text is reworded to avoid use of the term "must" for application requirements.

## Issue 7

PASC Interpretation 1003.2-92 \#151 (SD5-XCU-ERN-44) is applied.
Austin Group Interpretation 1003.1-2001 \#093 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
printf — write formatted output

## SYNOPSIS

```
    printf format [argument...]
```

## DESCRIPTION

The printf utility shall write formatted operands to the standard output. The argument operands shall be formatted under control of the format operand.

## OPTIONS

None.
OPERANDS
The following operands shall be supported:
format A string describing the format to use to write the remaining operands. See the EXTENDED DESCRIPTION section.
argument The strings to be written to standard output, under the control of format. See the EXTENDED DESCRIPTION section.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of printf:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_NUMERIC
Determine the locale for numeric formatting. It shall affect the format of numbers written using the e, $\mathrm{E}, \mathrm{f}, \mathrm{g}$, and G conversion specifier characters (if supported).
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

See the EXTENDED DESCRIPTION section.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

The format operand shall be used as the format string described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation with the following exceptions:

1. A <space> in the format string, in any context other than a flag of a conversion specification, shall be treated as an ordinary character that is copied to the output.
2. A ' $\Delta^{\prime}$ character in the format string shall be treated as a ' $\Delta^{\prime}$ character, not as a <space>.
3. In addition to the escape sequences shown in the Base Definitions volume of
 $\left.' \backslash r^{\prime}, \prime \backslash t^{\prime}, ' \backslash v^{\prime}\right), " \backslash d d d "$, where $d d d$ is a one, two, or three-digit octal number, shall be written as a byte with the numeric value specified by the octal number.
4. The implementation shall not precede or follow output from the $d$ or $u$ conversion specifiers with <blank>s not specified by the format operand.
5. The implementation shall not precede output from the o conversion specifier with zeros not specified by the format operand.
6. The $e, E, f, g$, and $G$ conversion specifiers need not be supported.
7. An additional conversion specifier character, b, shall be supported as follows. The argument shall be taken to be a string that may contain backslash-escape sequences. The following backslash-escape sequences shall be supported:

- The escape sequences listed in the Base Definitions volume of IEEE Std 1003.1-200x,
 ( $\left.\backslash \mathrm{v}^{\prime}\right)$, which shall be converted to the characters they represent
- " $\backslash 0$ ddd", where $d d d$ is a zero, one, two, or three-digit octal number that shall be converted to a byte with the numeric value specified by the octal number
- $10^{\prime}$, which shall not be written and shall cause printf to ignore any remaining characters in the string operand containing it, any remaining string operands, and any additional characters in the format operand
The interpretation of a backslash followed by any other sequence of characters is unspecified.
Bytes from the converted string shall be written until the end of the string or the number of bytes indicated by the precision specification is reached. If the precision is omitted, it shall be taken to be infinite, so all bytes up to the end of the converted string shall be written.

8. For each conversion specification that consumes an argument, the next argument operand shall be evaluated and converted to the appropriate type for the conversion as specified below.
9. The format operand shall be reused as often as necessary to satisfy the argument operands. Any extra c or s conversion specifiers shall be evaluated as if a null string argument were supplied; other extra conversion specifications shall be evaluated as if a zero argument were supplied. If the format operand contains no conversion specifications and argument operands are present, the results are unspecified.
10. If a character sequence in the format operand begins with $\mathrm{a}^{\prime} \%{ }^{\prime}$ character, but does not form a valid conversion specification, the behavior is unspecified.
The argument operands shall be treated as strings if the corresponding conversion specifier is $b$, $c$, or $s$; otherwise, it shall be evaluated as a C constant, as described by the ISO C standard, with the following extensions:

- A leading plus or minus sign shall be allowed.
- If the leading character is a single-quote or double-quote, the value shall be the numeric value in the underlying codeset of the character following the single-quote or doublequote.

If an argument operand cannot be completely converted into an internal value appropriate to the corresponding conversion specification, a diagnostic message shall be written to standard error and the utility shall not exit with a zero exit status, but shall continue processing any remaining operands and shall write the value accumulated at the time the error was detected to standard output.
It is not considered an error if an argument operand is not completely used for a cor s conversion or if a string operand's first or second character is used to get the numeric value of a character.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The floating-point formatting conversion specifications of printf() are not required because all arithmetic in the shell is integer arithmetic. The awk utility performs floating-point calculations and provides its own printf function. The bc utility can perform arbitrary-precision floatingpoint arithmetic, but does not provide extensive formatting capabilities. (This printf utility cannot really be used to format bc output; it does not support arbitrary precision.) Implementations are encouraged to support the floating-point conversions as an extension.
Note that this printf utility, like the printf() function defined in the System Interfaces volume of IEEE Std 1003.1-200x on which it is based, makes no special provision for dealing with multibyte characters when using the \%c conversion specification or when a precision is specified in a $\% \mathrm{~b}$ or \%s conversion specification. Applications should be extremely cautious using either of these features when there are multi-byte characters in the character set.
No provision is made in this volume of IEEE Std 1003.1-200x which allows field widths and precisions to be specified as ' ${ }^{\prime \prime}$ since the ${ }^{\prime * \prime}$ can be replaced directly in the format operand using shell variable substitution. Implementations can also provide this feature as an extension if they so choose.

Hexadecimal character constants as defined in the ISO C standard are not recognized in the format operand because there is no consistent way to detect the end of the constant. Octal character constants are limited to, at most, three octal digits, but hexadecimal character constants are only terminated by a non-hex-digit character. In the ISO C standard, the "\#\#" concatenation operator can be used to terminate a constant and follow it with a hexadecimal character to be written. In the shell, concatenation occurs before the printf utility has a chance to parse the end of the hexadecimal constant.
The \%b conversion specification is not part of the ISO C standard; it has been added here as a
portable way to process backslash escapes expanded in string operands as provided by the echo utility. See also the APPLICATION USAGE section of echo for ways to use printf as a replacement for all of the traditional versions of the echo utility.

If an argument cannot be parsed correctly for the corresponding conversion specification, the printf utility is required to report an error. Thus, overflow and extraneous characters at the end of an argument being used for a numeric conversion shall be reported as errors.

## EXAMPLES

To alert the user and then print and read a series of prompts:

```
printf "\aPlease fill in the following: \nName: "
read name
printf "Phone number: "
read phone
```

To read out a list of right and wrong answers from a file, calculate the percentage correctly, and print them out. The numbers are right-justified and separated by a single <tab>. The percentage is written to one decimal place of accuracy:

```
while read right wrong ; do
    percent=$(echo "scale=1;($right*100)/($right+$wrong)" | bc)
    printf "%2d right\t%2d wrong\t(%s%%)\n" \
            $right $wrong $percent
done < database_file
```

The command:

```
printf "%5d%4d\n" 1 21 321 4321 54321
```

produces:
121
3214321
543210
Note that the format operand is used three times to print all of the given strings and that a ' 0' was supplied by printf to satisfy the last $\% 4 \mathrm{~d}$ conversion specification.
The printf utility is required to notify the user when conversion errors are detected while producing numeric output; thus, the following results would be expected on an implementation with 32-bit twos-complement integers when \%d is specified as the format operand:

| Argument | Standard <br> Output | Diagnostic Output |
| :--- | :--- | :--- |
| 5 a | 5 | printf: "5a" not completely converted |
| 9999999999 | 2147483647 | printf: "9999999999" arithmetic overflow |
| -9999999999 | -2147483648 | printf: "9999999999" arithmetic overflow |
| ABC | 0 | printf: "ABC" expected numeric value |

The diagnostic message format is not specified, but these examples convey the type of information that should be reported. Note that the value shown on standard output is what would be expected as the return value from the strtol() function as defined in the System Interfaces volume of IEEE Std 1003.1-200x. A similar correspondence exists between \%u and $\operatorname{strtoul}()$ and $\% e, \% f$, and $\% g$ (if the implementation supports floating-point conversions) and strtod ().
In a locale using the ISO/IEC 646: 1991 standard as the underlying codeset, the command:

```
printf "%d\n" 3 +3 -3 \'3 \"+3 "'-3"
```

produces:

3 Numeric value of constant 3
3 Numeric value of constant 3
-3 Numeric value of constant -3
51 Numeric value of the character ' 3 ' in the ISO/IEC 646: 1991 standard codeset
43 Numeric value of the character ' + ' in the ISO/IEC 646: 1991 standard codeset
45 Numeric value of the character ' ${ }^{\prime}$ ' in the ISO/IEC 646: 1991 standard codeset
Note that in a locale with multi-byte characters, the value of a character is intended to be the value of the equivalent of the wchar_t representation of the character as described in the System Interfaces volume of IEEE Std 1003.1-200x.

## RATIONALE

The printf utility was added to provide functionality that has historically been provided by echo. However, due to irreconcilable differences in the various versions of echo extant, the version has few special features, leaving those to this new printf utility, which is based on one in the Ninth Edition system.
The EXTENDED DESCRIPTION section almost exactly matches the printf() function in the ISO C standard, although it is described in terms of the file format notation in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 5, File Format Notation.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 4.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

prs - print an SCCS file (DEVELOPMENT)

## SYNOPSIS

```
XSI
```

```
prs [-a] [-d dataspec] [-r[SID]] file...
```

prs [-a] [-d dataspec] [-r[SID]] file...
prs [-e|-l] -c cutoff [-d dataspec] file...
prs [-e|-l] -c cutoff [-d dataspec] file...
prs [-e|-l] -r[SID] [-d dataspec] file...

```
    prs [-e|-l] -r[SID] [-d dataspec] file...
```

## DESCRIPTION

The prs utility shall write to standard output parts or all of an SCCS file in a user-supplied format.

## OPTIONS

The prs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the -r option has an optional option-argument. This optional option-argument cannot be presented as a separate argument. The following options shall be supported:
-d dataspec Specify the output data specification. The dataspec shall be a string consisting of SCCS file data keywords (see Data Keywords (on page 751)) interspersed with optional user-supplied text.
${ }_{-r}[S I D] \quad$ Specify the SCCS identification string (SID) of a delta for which information is desired. If no SID option-argument is specified, the SID of the most recently created delta shall be assumed.
-e Request information for all deltas created earlier than and including the delta designated via the -r option or the date-time given by the -c option.
-1 Request information for all deltas created later than and including the delta designated via the -r option or the date-time given by the -c option.
-c cutoff Indicate the cutoff date-time, in the form:
YY[MM[DD[HH[MM[SS]]]]]
For the $Y Y$ component, values in the range [69,99] shall refer to years 1969 to 1999 inclusive, and values in the range $[00,68]$ shall refer to years 2000 to 2068 inclusive.
Note: It is expected that in a future version of IEEE Std 1003.1-200x the default century inferred from a 2 -digit year will change. (This would apply to all commands accepting a 2 -digit year as input.)
No changes (deltas) to the SCCS file that were created after the specified cutoff date-time shall be included in the output. Units omitted from the date-time default to their maximum possible values; for example, -c 7502 is equivalent to -c 750228235959 .
-a Request writing of information for both removed-that is, delta type $=R$ (see rmdel)-and existing-that is, delta type $=D$,-deltas. If the $-\mathbf{a}$ option is not specified, information for existing deltas only shall be provided.

## OPERANDS

The following operand shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the prs utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin
with $\mathbf{s .}$ ) and unreadable files shall be silently ignored.
If exactly one file operand appears, and it is ' - ', the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

## STDIN

The standard input shall be a text file used only when the file operand is specified as ' - '. Each line of the text file shall be interpreted as an SCCS pathname.

## INPUT FILES

Any SCCS files displayed are files of an unspecified format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of prs:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be a text file whose format is dependent on the data keywords specified with the -d option.

## Data Keywords

Data keywords specify which parts of an SCCS file shall be retrieved and output. All parts of an SCCS file have an associated data keyword. A data keyword may appear in a dataspec multiple times.

The information written by prs shall consist of:

1. The user-supplied text
2. Appropriate values (extracted from the SCCS file) substituted for the recognized data keywords in the order of appearance in the dataspec
The format of a data keyword value shall either be simple ( ${ }^{\prime} S^{\prime}$ ), in which keyword substitution is direct, or multi-line ( ${ }^{\prime} \mathrm{M}^{\prime}$ ).

User-supplied text shall be any text other than recognized data keywords. A <tab> shall be specified by ' $\backslash \mathrm{t}$ ' and <newline> by ' $\backslash \mathrm{n}$ '. When the -r option is not specified, the default dataspec shall be:
: PN: : $\backslash \mathrm{n} \backslash \mathrm{n}$
and the following dataspec shall be used for each selected delta:
$:$ Dt: \t: DL: \nMRs: $\backslash \mathrm{n}:$ MR:COMMENTS $: \backslash \mathrm{n}: \mathrm{C}:$

| SCCS File Data Keywords |  |  |  |  |

*** The line statistics are capped at 99 999. For example, if 100000 lines were unchanged in a certain revision, :Lu: shall produce the value 99999.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

1. The following example:
prs -d "User Names for :F: are: \n:UN:" s.file
might write to standard output:
User Names for s.file are:
xyz
131
abc
2. The following example:
prs -d "Delta for pgm :M:: :I: - :D: By :P:" -r s.file
might write to standard output:
Delta for pgm main.c: 3.7-77/12/01 By cas
3. As a special case:
prs s.file
might write to standard output:
s.file:
```
<blank line>
D 1.1 77/12/01 00:00:00 cas 1 000000/00000/00000
MRs:
bl78-12345
bl79-54321
COMMENTS:
this is the comment line for s.file initial delta
<blank line>
```

for each delta table entry of the $\mathbf{D}$ type. The only option allowed to be used with this special case is the -a option.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

## SEE ALSO

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The phrase "in which keyword substitution is followed by a <newline>" is deleted from the end of the second paragraph of Data Keywords (on page 751).

The interpretation of the $Y Y$ component of the -c cutoff argument is noted.
Issue 6
The normative text is reworded to emphasize the term "shall" for implementation requirements.
The Open Group Base Resolution bwg2001-007 is applied, updating the table in STDOUT with a note that line statistics are capped at 99999 for the :Li:, :Ld:, :Lu:, and :DL: keywords.

The Open Group Interpretation PIN4C. 00009 is applied.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

ps - report process status

## SYNOPSIS

XSI ps [-aA] [-defl] [-g grouplist] [-n namelist] [-u userlist]
[-G grouplist] [-o format]... [-p proclist] [-t termlist]
[-U userlist]

## DESCRIPTION

The $p s$ utility shall write information about processes, subject to having the appropriate privileges to obtain information about those processes.
By default, $p s$ shall select all processes with the same effective user ID as the current user and the same controlling terminal as the invoker.

## OPTIONS

The $p s$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a Write information for all processes associated with terminals. Implementations may omit session leaders from this list.
-A Write information for all processes.
xsi -d Write information for all processes, except session leaders.
xsi - Write information for all processes. (Equivalent to -A.)
XSI
xsI
-f Generate a full listing. (See the STDOUT section for the contents of a full listing.)

- $\mathbf{g}$ grouplist Write information for processes whose session leaders are given in grouplist. The application shall ensure that the grouplist is a single argument in the form of a <blank> or comma-separated list.
-G grouplist Write information for processes whose real group ID numbers are given in grouplist. The application shall ensure that the grouplist is a single argument in the form of a <blank> or comma-separated list.
xsi
-1 Generate a long listing. (See STDOUT for the contents of a long listing.)
-n namelist Specify the name of an alternative system namelist file in place of the default. The name of the default file and the format of a namelist file are unspecified.
-o format Write information according to the format specification given in format. This is fully described in the STDOUT section. Multiple -o options can be specified; the format specification shall be interpreted as the <space>-separated concatenation of all the format option-arguments.
-p proclist Write information for processes whose process ID numbers are given in proclist. The application shall ensure that the proclist is a single argument in the form of a <blank> or comma-separated list.
-t termlist Write information for processes associated with terminals given in termlist. The application shall ensure that the termlist is a single argument in the form of a <blank> or comma-separated list. Terminal identifiers shall be given in an implementation-defined format. On XSI-conformant systems, they shall be given in one of two forms: the device's filename (for example, tty04) or, if the device's filename starts with tty, just the identifier following the characters tty (for example,
"04").
-u userlist Write information for processes whose user ID numbers or login names are given in userlist. The application shall ensure that the userlist is a single argument in the form of a <blank> or comma-separated list. In the listing, the numerical user ID shall be written unless the -f option is used, in which case the login name shall be written.
-U userlist Write information for processes whose real user ID numbers or login names are given in userlist. The application shall ensure that the userlist is a single argument in the form of a <blank> or comma-separated list.

With the exception of $\mathbf{- 0}$ format, all of the options shown are used to select processes. If any are specified, the default list shall be ignored and $p s$ shall select the processes represented by the inclusive OR of all the selection-criteria options.

## OPERANDS

None.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of ps :
COLUMNS Override the system-selected horizontal display line size, used to determine the number of text columns to display. See the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables for valid values and results when it is unset or null.

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.

LC_TIME Determine the format and contents of the date and time strings displayed.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TZ Determine the timezone used to calculate date and time strings displayed. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

When the -o option is not specified, the standard output format is unspecified.
xSI On XSI-conformant systems, the output format shall be as follows. The column headings and descriptions of the columns in a $p s$ listing are given below. The precise meanings of these fields are implementation-defined. The letters ' $\mathrm{f}^{\prime}$ and ' $l^{\prime}$ (below) indicate the option (full or long) that shall cause the corresponding heading to appear; all means that the heading always appears. Note that these two options determine only what information is provided for a process; they do not determine which processes are listed.
\(\left.\begin{array}{lll}F \& (l) \& Flags (octal and additive) associated with the process. <br>
S \& (l) \& The state of the process. <br>
UID \& (f,l) \& The user ID number of the process owner; the login name is printed <br>

under the -f option.\end{array}\right]\)|  |  |
| :--- | :--- |
| PID | (all) |
| The process ID of the process; it is possible to kill a process if this |  |
| datum is known. |  |

A process that has exited and has a parent, but has not yet been waited for by the parent, shall be marked defunct.

Under the option $-\mathbf{f}, p s$ tries to determine the command name and arguments given when the process was created by examining memory or the swap area. Failing this, the command name, as it would appear without the option $-\mathbf{f}$, is written in square brackets.

The -o option allows the output format to be specified under user control.
The application shall ensure that the format specification is a list of names presented as a single argument, <blank> or comma-separated. Each variable has a default header. The default header can be overridden by appending an equals sign and the new text of the header. The rest of the characters in the argument shall be used as the header text. The fields specified shall be written in the order specified on the command line, and should be arranged in columns in the output. The field widths shall be selected by the system to be at least as wide as the header text (default or overridden value). If the header text is null, such as -o user=, the field width shall be at least as wide as the default header text. If all header text fields are null, no header line shall be written.

The following names are recognized in the POSIX locale:
ruser The real user ID of the process. This shall be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
user The effective user ID of the process. This shall be the textual user ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
rgroup The real group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
group The effective group ID of the process. This shall be the textual group ID, if it can be obtained and the field width permits, or a decimal representation otherwise.
pid The decimal value of the process ID.
ppid The decimal value of the parent process ID.
pgid The decimal value of the process group ID.
pcpu The ratio of CPU time used recently to CPU time available in the same period, expressed as a percentage. The meaning of "recently" in this context is unspecified. The CPU time available is determined in an unspecified manner.
vsz The size of the process in (virtual) memory in 1024 byte units as a decimal integer.
nice The decimal value of the nice value of the process; see nice.
etime In the POSIX locale, the elapsed time since the process was started, in the form:
[ [dd-]hh:] mm: ss
where $d d$ shall represent the number of days, $h h$ the number of hours, $m m$ the number of minutes, and $s s$ the number of seconds. The $d d$ field shall be a decimal integer. The $h h, m m$, and ss fields shall be two-digit decimal integers padded on the left with zeros.
time In the POSIX locale, the cumulative CPU time of the process in the form:
[dd-]hh:mm:ss
The $d d, h h, m m$, and $s s$ fields shall be as described in the etime specifier.
tty The name of the controlling terminal of the process (if any) in the same format used by the who utility.
comm The name of the command being executed (argv[0] value) as a string.
args The command with all its arguments as a string. The implementation may truncate this value to the field width; it is implementation-defined whether any further truncation occurs. It is unspecified whether the string represented is a version of the argument list as it was passed to the command when it started, or is a version of the arguments as they may have been modified by the application. Applications cannot depend on being able to modify their argument list and having that modification be reflected in the output of $p s$.
Any field need not be meaningful in all implementations. In such a case a hyphen $\left({ }^{\prime}-^{\prime}\right)$ should be output in place of the field value.
Only comm and args shall be allowed to contain <blank>s; all others shall not. Any implementation-defined variables shall be specified in the system documentation along with the default header and indicating whether the field may contain <blank>s.

The following table specifies the default header to be used in the POSIX locale corresponding to each format specifier.

Table 4-17 Variable Names and Default Headers in $p s$

| Format Specifier | Default Header | Format Specifier | Default Header |
| :--- | :--- | :--- | :--- |
| args | COMMAND | ppid | PPID |
| comm | COMMAND | rgroup | RGROUP |
| etime | ELAPSED | ruser | RUSER |
| group | GROUP | time | TIME |
| nice | NI | tty | TT |
| pcpu | \%CPU | user | USER |
| pgid | PGID | vsz | VSZ |
| pid | PID |  |  |

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Things can change while $p s$ is running; the snapshot it gives is only true for an instant, and might not be accurate by the time it is displayed.
The args format specifier is allowed to produce a truncated version of the command arguments. In some implementations, this information is no longer available when the $p s$ utility is executed.
If the field width is too narrow to display a textual D , the system may use a numeric version. Normally, the system would be expected to choose large enough field widths, but if a large number of fields were selected to write, it might squeeze fields to their minimum sizes to fit on one line. One way to ensure adequate width for the textual IDs is to override the default header for a field to make it larger than most or all user or group names.
There is no special quoting mechanism for header text. The header text is the rest of the argument. If multiple header changes are needed, multiple -o options can be used, such as:
ps -o "user=User Name" -o pid=Process
On some implementations, especially multi-level secure systems, $p s$ may be severely restricted and produce information only about child processes owned by the user.

## EXAMPLES

The command:
ps -o user, pid,ppid=MOM -o args
writes at least the following in the POSIX locale:

| USER | PID | MOM | COMMAND |
| ---: | ---: | ---: | :--- |
| helene | 34 | 12 | ps -o uid,pid,ppid=MOM -o args |

The contents of the COMMAND field need not be the same in all implementations, due to
possible truncation.

## RATIONALE

There is very little commonality between BSD and System V implementations of $p s$. Many options conflict or have subtly different usages. The standard developers attempted to select a set of options for the base standard that were useful on a wide range of systems and selected options that either can be implemented on both BSD and System V-based systems without breaking the current implementations or where the options are sufficiently similar that any changes would not be unduly problematic for users or implementors.
It is recognized that on some implementations, especially multi-level secure systems, $p s$ may be nearly useless. The default output has therefore been chosen such that it does not break historical implementations and also is likely to provide at least some useful information on most systems.
The major change is the addition of the format specification capability. The motivation for this invention is to provide a mechanism for users to access a wider range of system information, if the system permits it, in a portable manner. The fields chosen to appear in this volume of IEEE Std 1003.1-200x were arrived at after considering what concepts were likely to be both reasonably useful to the "average" user and had a reasonable chance of being implemented on a wide range of systems. Again it is recognized that not all systems are able to provide all the information and, conversely, some may wish to provide more. It is hoped that the approach adopted will be sufficiently flexible and extensible to accommodate most systems. Implementations may be expected to introduce new format specifiers.

The default output should consist of a short listing containing the process ID, terminal name, cumulative execution time, and command name of each process.
The preference of the standard developers would have been to make the format specification an operand of the ps command. Unfortunately, BSD usage precluded this.
At one time a format was included to display the environment array of the process. This was deleted because there is no portable way to display it.
The - A option is equivalent to the BSD $-\mathbf{g}$ and the SVID -e. Because the two systems differed, a mnemonic compromise was selected.

The -a option is described with some optional behavior because the SVID omits session leaders, but BSD does not.

In an early proposal, format specifiers appeared for priority and start time. The former was not defined adequately in this volume of IEEE Std 1003.1-200x and was removed in deference to the defined nice value; the latter because elapsed time was considered to be more useful.
In a new BSD version of $p s$, a $-\mathbf{O}$ option can be used to write all of the default information, followed by additional format specifiers. This was not adopted because the default output is implementation-defined. Nevertheless, this is a useful option that should be reserved for that purpose. In the -o option for the POSIX Shell and Utilities $p s$, the format is the concatenation of each -o. Therefore, the user can have an alias or function that defines the beginning of their desired format and add more fields to the end of the output in certain cases where that would be useful.

The format of the terminal name is unspecified, but the descriptions of $p s$, talk, who, and write require that they all use the same format.

The pcpu field indicates that the CPU time available is determined in an unspecified manner. This is because it is difficult to express an algorithm that is useful across all possible machine architectures. Historical counterparts to this value have attempted to show percentage of use in the recent past, such as the preceding minute. Frequently, these values for all processes did not add up to $100 \%$. Implementations are encouraged to provide data in this field to users that will
help them identify processes currently affecting the performance of the system.

## FUTURE DIRECTIONS

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The normative text is reworded to avoid use of the term "must" for application requirements.
The $T Z$ entry is added to the ENVIRONMENT VARIABLES section.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
pwd - return working directory name

## SYNOPSIS

```
pwd [-L|-P]
```

DESCRIPTION
The pwd utility shall write to standard output an absolute pathname of the current working directory, which does not contain the filenames dot or dot-dot.

## OPTIONS

The pwd utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-L If the PWD environment variable contains an absolute pathname of the current directory that does not contain the filenames dot or dot-dot, pwd shall write this pathname to standard output. Otherwise, the $-\mathbf{L}$ option shall behave as the $-\mathbf{P}$ option.
-P The absolute pathname written shall not contain filenames that, in the context of the pathname, refer to files of type symbolic link.

If both $-\mathbf{L}$ and $-\mathbf{P}$ are specified, the last one shall apply. If neither $-\mathbf{L}$ nor $-\mathbf{P}$ is specified, the $p w d$ utility shall behave as if $-\mathbf{L}$ had been specified.
OPERANDS
None.
STDIN
Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $p w d$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L \quad$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
$P W D \quad$ An absolute pathname of the current working directory. If an application sets or unsets the value of $P W D$, the behavior of $p w d$ is unspecified.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The pwd utility output is an absolute pathname of the current working directory:
"\%s\n", <directory pathname>
STDERR
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If an error is detected, output shall not be written to standard output, a diagnostic message shall be written to standard error, and the exit status is not zero.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

Some implementations have historically provided $p w d$ as a shell special built-in command.
In most utilities, if an error occurs, partial output may be written to standard output. This does not happen in historical implementations of $p w d$. Because pwd is frequently used in historical shell scripts without checking the exit status, it is important that the historical behavior is required here, therefore, the CONSEQUENCES OF ERRORS section specifically disallows any partial output being written to standard output.
A previous version of this standard stated that the PWD environment variable was affected when the $-\mathbf{P}$ option was in effect. This was incorrect; conforming implementations do not do this.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The $-\mathbf{P}$ and - $\mathbf{L}$ options are added to describe actions relating to symbolic links as specified in the IEEE P1003.2b draft standard.

Austin Group Interpretation 1003.1-2001 \#097 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

qalter - alter batch job

## SYNOPSIS

```
OB BE qalter [-a date_time] [-A account_string] [-c interval] [-e path_name]
    [-h hold_list] [-j join_list] [-k keep_list] [-l resource_list]
    [-m mail_options] [-M mail_list] [-N name] [-o path_name]
    [-p priority] [-r y|n] [-S path_name_list] [-u user_list]
    job_identifier...
```

## DESCRIPTION

The attributes of a batch job are altered by a request to the batch server that manages the batch job. The qalter utility is a user-accessible batch client that requests the alteration of the attributes of one or more batch jobs.
The qalter utility shall alter the attributes of those batch jobs, and only those batch jobs, for which a batch job_identifier is presented to the utility.

The qalter utility shall alter the attributes of batch jobs in the order in which the batch job_identifiers are presented to the utility.
If the qalter utility fails to process a batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.
For each batch job_identifier for which the qalter utility succeeds, each attribute of the identified batch job shall be altered as indicated by all the options presented to the utility.
For each identified batch job for which the qalter utility fails, the utility shall not alter any attribute of the batch job.
For each batch job that the qalter utility processes, the utility shall not modify any attribute other than those required by the options and option-arguments presented to the utility.

The qalter utility shall alter batch jobs by sending a Modify Job Request to the batch server that manages each batch job. At the time the qalter utility exits, it shall have modified the batch job corresponding to each successfully processed batch job_identifier. An attempt to alter the attributes of a batch job in the RUNNING state is implementation-defined.

## OPTIONS

The qalter utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-a date_time Redefine the time at which the batch job becomes eligible for execution.
The date_time argument shall be in the same form and represent the same time as for the touch utility. The time so represented shall be set into the Execution_Time attribute of the batch job. If the time specified is earlier than the current time, the -a option shall have no effect.
-A account_string
Redefine the account to which the resource consumption of the batch job should be charged.
The syntax of the account_string option-argument is unspecified.
The qalter utility shall set the Account_Name attribute of the batch job to the value of the account_string option-argument.
-c interval Redefine whether the batch job should be checkpointed, and if so, how often.
The qalter utility shall accept a value for the interval option-argument that is one of the following:
$\mathrm{n} \quad \begin{aligned} & \text { No checkpointing is to be performed on the batch job } \\ & \text { (NO_CHECKPOINT). }\end{aligned}$
s Checkpointing is to be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).
c Automatic periodic checkpointing is to be performed at the Minimum_Cpu_Interval attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).
$\mathrm{c}=$ minutes Automatic periodic checkpointing is to be performed every minutes of CPU time, or every Minimum_Cpu_Interval minutes, whichever is greater. The minutes argument shall conform to the syntax for unsigned integers and shall be greater than zero.

An implementation may define other checkpoint intervals. The conformance document for an implementation shall describe any alternative checkpoint intervals, how they are specified, their internal behavior, and how they affect the behavior of the utility.

The qalter utility shall set the Checkpoint attribute of the batch job to the value of the interval option-argument.

- $\mathbf{p a t h}$ _name

Redefine the path to be used for the standard error stream of the batch job.
The qalter utility shall accept a path_name option-argument that conforms to the syntax of the path_name element defined in the System Interfaces volume of IEEE Std 1003.1-200x, which can be preceded by a host name element of the form hostname:-

If the path_name option-argument constitutes an absolute pathname, the qalter utility shall set the Error_Path attribute of the batch job to the value of the path_name option-argument, including the host name element, if present.
If the path_name option-argument constitutes a relative pathname and no host name element is specified, the qalter utility shall set the Error_Path attribute of the batch job to the value of the absolute pathname derived by expanding the path name option-argument relative to the current directory of the process that executes the qalter utility.
If the path_name option-argument constitutes a relative pathname and a host name element is specified, the qalter utility shall set the Error_Path attribute of the batch job to the value of the option-argument without expansion.

If the path_name option-argument does not include a host name element, the qalter utility shall prefix the pathname in the Error_Path attribute with hostname:, where hostname is the name of the host upon which the qalter utility is being executed.
-h hold_list Redefine the types of holds, if any, on the batch job. The qalter -h option shall accept a value for the hold_list option-argument that is a string of alphanumeric characters in the portable character set.
The qalter utility shall accept a value for the hold_list option-argument that is a string of one or more of the characters ' $u$ ', ' $s$ ', or ' $o^{\prime}$, or the single character ' n '. For each unique character in the hold_list option-argument, the qalter utility shall add a value to the Hold_Types attribute of the batch job as follows, each
representing a different hold type:

## u USER

s SYSTEM

- OPERATOR

If any of these characters are duplicated in the hold_list option-argument, the duplicates shall be ignored. An existing Hold_Types attribute can be cleared by the hold type:

## n NO_HOLD

The qalter utility shall consider it an error if any hold type other than ' $n$ ' is combined with hold type ' n '. Strictly conforming applications shall not repeat any of the characters ' $u$ ', ' $\mathrm{s}^{\prime}$, ' $\mathrm{o}^{\prime}$, or $\mathrm{o}^{\prime} \mathrm{n}$ ' within the hold_list option-argument. The qalter utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.
-j join_list Redefine which streams of the batch job are to be merged. The qalter -j option shall accept a value for the join_list option-argument that is a string of alphanumeric characters in the portable character set.

The qalter utility shall accept a join_list option-argument that consists of one or more of the characters ' $e$ ' and ' $o$ ', or the single character ' $n$ '.
All of the other batch job output streams specified shall be merged into the output stream represented by the character listed first in the join_list option-argument.
For each unique character in the join_list option-argument, the qalter utility shall add a value to the Join_Path attribute of the batch job as follows, each representing a different batch job stream to join:
e The standard error of the batch job (JOIN_STD_ERROR).

- The standard output of the batch job (JOIN_STD_OUTPUT).

An existing Join_Path attribute can be cleared by the join type:
n NO_JOIN
If ' $n$ ' is specified, then no files are joined. The qalter utility shall consider it an error if any join type other than ' $n$ ' is combined with join type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $e^{\prime}$, ' $o^{\prime}$, or ' n ' within the join_list option-argument. The qalter utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other join types. The conformance document for an implementation shall describe any additional batch job streams, how they are specified, their internal behavior, and how they affect the behavior of the utility.
$-\mathbf{k}$ keep_list Redefine which output of the batch job to retain on the execution host.
The qalter $\mathbf{- k}$ option shall accept a value for the keep_list option-argument that is a string of alphanumeric characters in the portable character set.
The qalter utility shall accept a keep_list option-argument that consists of one or more of the characters ' $e^{\prime}$ and ' $\mathrm{o}^{\prime}$, or the single character ' n '.

For each unique character in the keep_list option-argument, the qalter utility shall add a value to the Keep_Files attribute of the batch job as follows, each representing a different batch job stream to keep:
e The standard error of the batch job (KEEP_STD_ERROR).

- The standard output of the batch job (KEEP_STD_OUTPUT).

If both 'e' and 'o' are specified, then both files are retained. An existing Keep_Files attribute can be cleared by the keep type:

## n NO_KEEP

If ' $n$ ' is specified, then no files are retained. The qalter utility shall consider it an error if any keep type other than ' $n$ ' is combined with keep type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $\mathrm{e}^{\prime}, \mathrm{\prime} \mathrm{o}^{\prime}$, or ' $n$ ' within the keep_list option-argument. The qalter utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other keep types. The conformance document for an implementation shall describe any additional keep types, how they are specified, their internal behavior, and how they affect the behavior of the utility.
-1 resource_list
Redefine the resources that are allowed or required by the batch job.
The qalter utility shall accept a resource_list option-argument that conforms to the following syntax:
resource=value [, resource=value, ,...]
The galter utility shall set one entry in the value of the Resource_List attribute of the batch job for each resource listed in the resource_list option-argument.

Because the list of supported resource names might vary by batch server, the qalter utility shall rely on the batch server to validate the resource names and associated values. See Section 3.3.3 for a means of removing keyword=value (and value@keyword) pairs and other general rules for list-oriented batch job attributes.
-m mail_options
Redefine the points in the execution of the batch job at which the batch server is to send mail about a change in the state of the batch job.
The qalter-m option shall accept a value for the mail_options option-argument that is a string of alphanumeric characters in the portable character set.
The qalter utility shall accept a value for the mail_options option-argument that is a string of one or more of the characters ' $\mathrm{e}^{\prime}$, ' $\mathrm{b}^{\prime}$ ', and ' $\mathrm{a}^{\prime}$ ', or the single character ' n '. For each unique character in the mail_options option-argument, the qalter utility shall add a value to the Mail_Users attribute of the batch job as follows, each representing a different time during the life of a batch job at which to send mail:

```
e MAIL_AT_EXIT
b MAIL_AT_BEGINNING
a MAIL_AT_ABORT
```

If any of these characters are duplicated in the mail_options option-argument, the duplicates shall be ignored.

An existing Mail_Points attribute can be cleared by the mail type:
n NO_MAIL
If ' $n$ ' is specified, then mail is not sent. The qalter utility shall consider it an error if any mail type other than ' $n$ ' is combined with mail type ' $n$ '. Strictly conforming applications shall not repeat any of the characters ' $e^{\prime},{ }^{\prime} b^{\prime},{ }^{\prime} a^{\prime}$, or ' n ' within the mail_options option-argument. The qalter utility shall permit the repetition of characters but shall not assign additional meaning to the repeated characters.

An implementation may define other mail types. The conformance document for an implementation shall describe any additional mail types, how they are specified, their internal behavior, and how they affect the behavior of the utility.
-M mail_list Redefine the list of users to which the batch server that executes the batch job is to send mail, if the batch server sends mail about the batch job.
The syntax of the mail_list option-argument is unspecified. If the implementation of the qalter utility uses a name service to locate users, the utility shall accept the syntax used by the name service.
If the implementation of the qalter utility does not use a name service to locate users, the implementation shall accept the following syntax for user names:
mail_address[, mail_address, . . . ]
The interpretation of mail_address is implementation-defined.
The qalter utility shall set the Mail_Users attribute of the batch job to the value of the mail_list option-argument.
-N name Redefine the name of the batch job.
The qalter $-\mathbf{N}$ option shall accept a value for the name option-argument that is a string of up to 15 alphanumeric characters in the portable character set where the first character is alphabetic.

The syntax of the name option-argument is unspecified.
The qalter utility shall set the Job_Name attribute of the batch job to the value of the name option-argument.

- o path_name

Redefine the path for the standard output of the batch job.
The qalter utility shall accept a path_name option-argument that conforms to the syntax of the path_name element defined in the System Interfaces volume of IEEE Std 1003.1-200x, which can be preceded by a host name element of the form hostname:.
If the path_name option-argument constitutes an absolute pathname, the qalter utility shall set the Output_Path attribute of the batch job to the value of the path_name option-argument.
If the path_name option-argument constitutes a relative pathname and no host name element is specified, the qalter utility shall set the Output_Path attribute of the batch job to the absolute pathname derived by expanding the path_name optionargument relative to the current directory of the process that executes the qalter utility.
If the path_name option-argument constitutes a relative pathname and a host name element is specified, the qalter utility shall set the Output_Path attribute of the batch
job to the value of the path_name option-argument without any expansion of the pathname.
If the path_name option-argument does not include a host name element, the qalter utility shall prefix the pathname in the Output_Path attribute with hostname:, where hostname is the name of the host upon which the qalter utility is being executed.
-p priority Redefine the priority of the batch job.
The qalter utility shall accept a value for the priority option-argument that conforms to the syntax for signed decimal integers, and which is not less than -1024 and not greater than 1023.

The qalter utility shall set the Priority attribute of the batch job to the value of the priority option-argument.
$-\mathbf{r}_{\mathrm{y}} \mid \mathrm{n} \quad$ Redefine whether the batch job is rerunnable.
If the value of the option-argument is ' Y ', the qalter utility shall set the Rerunable attribute of the batch job to TRUE.

If the value of the option-argument is ' n ', the qalter utility shall set the Rerunable attribute of the batch job to FALSE.

The qalter utility shall consider it an error if any character other than ' y ' or ' n ' is specified in the option-argument.
-S path_name_list
Redefine the shell that interprets the script at the destination system.
The qalter utility shall accept a path_name_list option-argument that conforms to the following syntax:
pathname [@host][, pathname[@host], ...]
The qalter utility shall accept only one pathname that is missing a corresponding host name. The galter utility shall allow only one pathname per named host.

The qalter utility shall add a value to the Shell_Path_List attribute of the batch job for each entry in the path_name_list option-argument. See Section 3.3.3 for a means of removing keyword=value (and value@keyword) pairs and other general rules for list-oriented batch job attributes.
$-\mathbf{u}$ user_list Redefine the user name under which the batch job is to run at the destination system.
The qalter utility shall accept a user_list option-argument that conforms to the following syntax:
username[@host] [, , username [@host], , . . .]
The qalter utility shall accept only one user name that is missing a corresponding host name. The qalter utility shall accept only one user name per named host.

The qalter utility shall add a value to the User_List attribute of the batch job for each entry in the user_list option-argument. See Section 3.3.3 for a means of removing keyword=value (and value@keyword) pairs and other general rules for list-oriented batch job attributes.

## OPERANDS

The qalter utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qalter:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME Determine the login name of the user.
$T Z \quad$ Determine the timezone used to interpret the date-time option-argument. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

None.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qalter utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qalter utility attempts to locate the batch job on other batch servers is implementation-defined.

## APPLICATION USAGE <br> None.

## EXAMPLES

None.

## RATIONALE

The qalter utility allows users to change the attributes of a batch job.
As a means of altering a queued job, the qalter utility is superior to deleting and requeuing the batch job insofar as an altered job retains its place in the queue with some traditional selection algorithms. In addition, the qalter utility is both shorter and simpler than a sequence of qdel and qsub utilities.
The result of an attempt on the part of a user to alter a batch job in a RUNNING state is implementation-defined because a batch job in the RUNNING state will already have opened its output files and otherwise performed any actions indicated by the options in effect at the time the batch job began execution.
The options processed by the qalter utility are identical to those of the qsub utility, with a few exceptions: $\mathbf{- V}, \mathbf{-}$, and $-\mathbf{q}$. The $-\mathbf{V}$ and $-\mathbf{v}$ are inappropriate for the qalter utility, since they capture potentially transient environment information from the submitting process. The $-\mathbf{q}$ option would specify a new queue, which would largely negate the previously stated advantage of using qalter; furthermore, the qmove utility provides a superior means of moving jobs.
Each of the following paragraphs provides the rationale for a qalter option.
Additional rationale concerning these options can be found in the rationale for the qsub utility.
The -a option allows users to alter the date and time at which a batch job becomes eligible to run.

The -A option allows users to change the account that will be charged for the resources consumed by the batch job. Support for the -A option is mandatory for conforming implementations of galter, even though support of accounting is optional for servers. Whether or not to support accounting is left to the implementor of the server, but mandatory support of the -A option assures users of a consistent interface and allows them to control accounting on servers that support accounting.
The -c option allows users to alter the checkpointing interval of a batch job. A checkpointing system, which is not defined by IEEE Std 1003.1-200x, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of IEEE Std 1003.1-200x provides the checkpointing interval option. Support for checkpointing is optional for servers.
The -e option allows users to alter the name and location of the standard error stream written by a batch job. However, the path of the standard error stream is meaningless if the value of the Join_Path attribute of the batch job is TRUE.

The -h option allows users to set the hold type in the Hold_Types attribute of a batch job. The qhold and qrls utilities add or remove hold types to the Hold_Types attribute, respectively. The -h option has been modified to allow for implementation-defined hold types.
The $\mathbf{j}$ option allows users to alter the decision to join (merge) the standard error stream of the batch job with the standard output stream of the batch job.
The -1 option allows users to change the resource limits imposed on a batch job.
The $-\mathbf{m}$ option allows users to modify the list of points in the life of a batch job at which the designated users will receive mail notification.

The $-\mathbf{M}$ option allows users to alter the list of users who will receive notification about events in the life of a batch job.

The $\mathbf{- N}$ option allows users to change the name of a batch job.
The -o option allows users to alter the name and path to which the standard output stream of the batch job will be written.

The $-\mathbf{P}$ option allows users to modify the priority of a batch job. Support for priority is optional for batch servers.

The -r option allows users to alter the rerunability status of a batch job.
The - S option allows users to change the name and location of the shell image that will be invoked to interpret the script of the batch job. This option has been modified to allow a list of shell name and locations associated with different hosts.
The -u option allows users to change the user identifier under which the batch job will execute.
The job_identifier operand syntax is provided so that the user can differentiate between the originating and destination (or executing) batch server. These may or may not be the same. The .server_name portion identifies the originating batch server, while the @server portion identifies the destination batch server.

Historically, the qalter utility has been a component of the Network Queuing System (NQS), the existing practice from which this utility has been derived.

## FUTURE DIRECTIONS

The qalter utility may be removed in a future version.

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
The TZ entry is added to the ENVIRONMENT VARIABLES section.
IEEE PASC Interpretation 1003.2 \#182 is applied, clarifying the description of the $-\mathbf{a}$ option.
Issue 7
The qalter utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
qdel - delete batch jobs

## SYNOPSIS

OB BE qdel job_identifier...

## DESCRIPTION

A batch job is deleted by sending a request to the batch server that manages the batch job. A batch job that has been deleted is no longer subject to management by batch services.
The qdel utility is a user-accessible client of batch services that requests the deletion of one or more batch jobs.
The qdel utility shall request a batch server to delete those batch jobs for which a batch job_identifier is presented to the utility.
The qdel utility shall delete batch jobs in the order in which their batch job_identifiers are presented to the utility.

If the qdel utility fails to process any batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.
The qdel utility shall delete each batch job by sending a Delete Job Request to the batch server that manages the batch job.
The qdel utility shall not exit until the batch job corresponding to each successfully processed batch job_identifier has been deleted.

## OPTIONS

None.

## OPERANDS

The qdel utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qdel:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

An implementation of the qdel utility may write informative messages to standard output.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qdel utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qdel utility waits to output the diagnostic message while attempting to locate the job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qdel utility allows users and administrators to delete jobs.
The qdel utility provides functionality that is not otherwise available. For example, the kill utility of the operating system does not suffice. First, to use the kill utility, the user might have to log in on a remote node, because the kill utility does not operate across the network. Second, unlike qdel, kill cannot remove jobs from queues. Lastly, the arguments of the qdel utility are job identifiers rather than process identifiers, and so this utility can be passed the output of the qselect utility, thus providing users with a means of deleting a list of jobs.
Because a set of jobs can be selected using the qselect utility, the qdel utility has not been complicated with options that provide for selection of jobs. Instead, the batch jobs to be deleted are identified individually by their job identifiers.

Historically, the qdel utility has been a component of NQS, the existing practice on which it is based. However, the qdel utility defined in this volume of IEEE Std 1003.1-200x does not provide an option for specifying a signal number to send to the batch job prior to the killing of the process; that capability has been subsumed by the qsig utility.

A discussion was held about the delays of networking and the possibility that the batch server may never respond, due to a down router, down batch server, or other network mishap. The DESCRIPTION records this under the words "fails to process any job identifier". In the broad sense, the network problem is also an error, which causes the failure to process the batch job identifier.

## FUTURE DIRECTIONS

The qdel utility may be removed in a future version.

## SEE ALSO

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.
Issue 7
The qdel utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
qhold - hold batch jobs

## SYNOPSIS

OB BE qhold [-h hold_list] job_identifier...

## DESCRIPTION

A hold is placed on a batch job by a request to the batch server that manages the batch job. A batch job that has one or more holds is not eligible for execution. The qhold utility is a useraccessible client of batch services that requests one or more types of hold to be placed on one or more batch jobs.
The qhold utility shall place holds on those batch jobs for which a batch job_identifier is presented to the utility.
The qhold utility shall place holds on batch jobs in the order in which their batch job_identifiers are presented to the utility. If the qhold utility fails to process any batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.

The qhold utility shall place holds on each batch job by sending a Hold Job Request to the batch server that manages the batch job.

The qhold utility shall not exit until holds have been placed on the batch job corresponding to each successfully processed batch job_identifier.

## OPTIONS

The qhold utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:
-h hold_list Define the types of holds to be placed on the batch job.
The qhold -h option shall accept a value for the hold_list option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The qhold utility shall accept a value for the hold_list option-argument that is a string of one or more of the characters ' u ', ' s ', or ' $\mathrm{o}^{\prime}$ ', or the single character ' n '.
For each unique character in the hold_list option-argument, the qhold utility shall add a value to the Hold_Types attribute of the batch job as follows, each representing a different hold type:
u USER
s SYSTEM

- OPERATOR

If any of these characters are duplicated in the hold_list option-argument, the duplicates shall be ignored.
An existing Hold_Types attribute can be cleared by the following hold type:
n NO_HOLD
The qhold utility shall consider it an error if any hold type other than ' $n$ ' is combined with hold type ' $n$ '.

Strictly conforming applications shall not repeat any of the characters ' $u$ ', ' $s^{\prime}$, ' $\mathrm{O}^{\prime}$, or ' n ' within the hold_list option-argument. The qhold utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.

If the $-\mathbf{h}$ option is not presented to the qhold utility, the implementation shall set the Hold_Types attribute to USER.

## OPERANDS

The qhold utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qhold:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L \quad$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES

0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qhold utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qhold utility waits to output the diagnostic message while attempting to locate the job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qhold utility allows users to place a hold on one or more jobs. A hold makes a batch job ineligible for execution.

The qhold utility has options that allow the user to specify the type of hold. Should the user wish to place a hold on a set of jobs that meet a selection criteria, such a list of jobs can be acquired using the qselect utility.
The -h option allows the user to specify the type of hold that is to be placed on the job. This option allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The USER and OPERATOR holds are distinct. The batch server that manages the batch job will verify that the user is authorized to set the specified hold for the batch job.
Mail is not required on hold because the administrator has the tools and libraries to build this option if he or she wishes.
Historically, the qhold utility has been a part of some existing batch systems, although it has not traditionally been a part of the NQS.

## FUTURE DIRECTIONS

The qhold utility may be removed in a future version.

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.
Issue 7
The qhold utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
qmove - move batch jobs

## SYNOPSIS

OB BE qmove destination job_identifier...

## DESCRIPTION

To move a batch job is to remove the batch job from the batch queue in which it resides and instantiate the batch job in another batch queue. A batch job is moved by a request to the batch server that manages the batch job. The qmove utility is a user-accessible batch client that requests the movement of one or more batch jobs.
The qmove utility shall move those batch jobs, and only those batch jobs, for which a batch job_identifier is presented to the utility.

The qmove utility shall move batch jobs in the order in which the corresponding batch job_identifiers are presented to the utility.

If the qmove utility fails to process a batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.

The qmove utility shall move batch jobs by sending a Move Job Request to the batch server that manages each batch job. The qmove utility shall not exit before the batch jobs corresponding to all successfully processed batch job_identifiers have been moved.

## OPTIONS

None.

## OPERANDS

The qmove utility shall accept one operand that conforms to the syntax for a destination (see Section 3.3.2 (on page 123)).

The qmove utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qmove:
$L A N G \quad$ Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

None.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qmove utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qmove utility waits to output the diagnostic message while attempting to locate the job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qmove utility allows users to move jobs between queues.
The alternative to using the qmove utility-deleting the batch job and requeuing it-entails considerably more typing.

Since the means of selecting jobs based on attributes has been encapsulated in the qselect utility, the only option of the qmove utility concerns authorization. The $-\mathbf{u}$ option provides the user with the convenience of changing the user identifier under which the batch job will execute. Minimalism and consistency have taken precedence over convenience; the -u option has been deleted because the equivalent capability exists with the $-\mathbf{u}$ option of the qalter utility.

## FUTURE DIRECTIONS

The qmove utility may be removed in a future version.

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.

Issue 7
The qmove utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

qmsg - send message to batch jobs

## SYNOPSIS

OB BE qmsg [-E] [-O] message_string job_identifier...

## DESCRIPTION

To send a message to a batch job is to request that a server write a message string into one or more output files of the batch job. A message is sent to a batch job by a request to the batch server that manages the batch job. The qmsg utility is a user-accessible batch client that requests the sending of messages to one or more batch jobs.
The qmsg utility shall write messages into the files of batch jobs by sending a Job Message Request to the batch server that manages the batch job. The qmsg utility shall not directly write the message into the files of the batch job.
The qmsg utility shall send a Job Message Request for those batch jobs, and only those batch jobs, for which a batch job_identifier is presented to the utility.

The qmsg utility shall send Job Message Requests for batch jobs in the order in which their batch job_identifiers are presented to the utility.
If the qmsg utility fails to process any batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.
The qmsg utility shall not exit before a Job Message Request has been sent to the server that manages the batch job that corresponds to each successfully processed batch job_identifier.

## OPTIONS

The qmsg utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-E Specify that the message is written to the standard error of each batch job. The qmsg utility shall write the message into the standard error of the batch job.
-O Specify that the message is written to the standard output of each batch job.
The qmsg utility shall write the message into the standard output of the batch job.
If neither the $-\mathbf{O}$ nor the $-\mathbf{E}$ option is presented to the qmsg utility, the utility shall write the message into an implementation-defined file. The conformance document for the implementation shall describe the name and location of the implementation-defined file. If both the $-\mathbf{O}$ and the $-\mathbf{E}$ options are presented to the qmsg utility, then the utility shall write the messages to both standard output and standard error.

## OPERANDS

The qmsg utility shall accept a minimum of two operands, message_string and one or more batch job_identifiers.
The message_string operand shall be the string to be written to one or more output files of the batch job followed by a <newline>. If the string contains <blank>s, then the application shall ensure that the string is quoted. The message_string shall be encoded in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).
All remaining operands are batch job_identifiers that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $q m s g$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME Determine the login name of the user.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

None.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES <br> None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qmsg utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qmsg utility waits to output the diagnostic message while attempting to locate the job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qmsg utility allows users to write messages into the output files of running jobs. Users, including operators and administrators, have a number of occasions when they want to place messages in the output files of a batch job. For example, if a disk that is being used by a batch job is showing errors, the operator might note this in the standard error stream of the batch job.
The options of the qmsg utility provide users with the means of placing the message in the output stream of their choice. The default output stream for the message-if the user does not designate an output stream-is implementation-defined, since many implementations will provide, as an extension to this volume of IEEE Std 1003.1-200x, a log file that shows the history of utility execution.
If users wish to send a message to a set of jobs that meet a selection criteria, the qselect utility can be used to acquire the appropriate list of job identifiers.

The -E option allows users to place the message in the standard error stream of the batch job. The $\mathbf{- O}$ option allows users to place the message in the standard output stream of the batch job.
Historically, the qmsg utility is an existing practice in the offerings of one or more implementors of an NQS-derived batch system. The utility has been found to be useful enough that it deserves to be included in this volume of IEEE Std 1003.1-200x.

## FUTURE DIRECTIONS

The qmsg utility may be removed in a future version.

The qmsg utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

qrerun - rerun batch jobs

## SYNOPSIS

```
OB BE qrerun job_identifier...
```

## DESCRIPTION

To rerun a batch job is to terminate the session leader of the batch job, delete any associated checkpoint files, and return the batch job to the batch queued state. A batch job is rerun by a request to the batch server that manages the batch job. The qrerun utility is a user-accessible batch client that requests the rerunning of one or more batch jobs.
The qrerun utility shall rerun those batch jobs for which a batch job_identifier is presented to the utility.

The qrerun utility shall rerun batch jobs in the order in which their batch job_identifiers are presented to the utility.

If the qrerun utility fails to process any batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.
The qrerun utility shall rerun batch jobs by sending a Rerun Job Request to the batch server that manages each batch job.
For each successfully processed batch job_identifier, the qrerun utility shall have rerun the corresponding batch job at the time the utility exits.

## OPTIONS

None.

## OPERANDS

The qrerun utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qrerun:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

None.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the grerun utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qrerun utility waits to output the diagnostic message while attempting to locate the job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qrerun utility allows users to cause jobs in the running state to exit and rerun.
The qrerun utility is a new utility, vis-a-vis existing practice, that has been defined in this volume of IEEE Std 1003.1-200x to correct user-perceived deficiencies in the existing practice.

## FUTURE DIRECTIONS

The qrerun utility may be removed in a future version.

## SEE ALSO

Chapter 3

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
qrls - release batch jobs

## SYNOPSIS

OB BE qrls [-h hold_list] job_identifier...

## DESCRIPTION

A batch job might have one or mor
n NO_HOLD
The qrls utility shall consider it an error if any hold type other than ' $n$ ' is combined with hold type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $u^{\prime},{ }^{\prime} s^{\prime}$, ' $\mathrm{o}^{\prime}$, or ' n ' within the hold_list option-argument. The qrls utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.
If the $-\mathbf{h}$ option is not presented to the qrls utility, the implementation shall remove the USER hold in the Hold_Types attribute.

## OPERANDS

The qrls utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qurs:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME Determine the login name of the user.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

None.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qrls utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qrls utility waits to output the diagnostic message while attempting to locate the job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qrls utility allows users, operators, and administrators to remove holds from jobs.
The qrls utility does not support any job selection options or wildcard arguments. Users may acquire a list of jobs selected by attributes using the qselect utility. For example, a user could select all of their held jobs.
The -h option allows the user to specify the type of hold that is to be removed. This option allows for USER, SYSTEM, OPERATOR, and implementation-defined hold types. The batch server that manages the batch job will verify whether the user is authorized to remove the specified hold for the batch job. If more than one type of hold has been placed on the batch job, a user may wish to remove only some of them.
Mail is not required on release because the administrator has the tools and libraries to build this option if required.

The qrls utility is a new utility vis-a-vis existing practice; it has been defined in this volume of IEEE Std 1003.1-200x as the natural complement to the qhold utility.

## FUTURE DIRECTIONS

The qrls utility may be removed in a future version.

## SEE ALSO

Chapter 3 (on page 101), qhold, qselect

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.
Issue 7
The qrls utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

qselect - select batch jobs

## SYNOPSIS

```
OB BE
qselect [-a [op]date_time] [-A account_string] [-c [op]interval]
    [-h hold_list] [-l resource_list] [-N name] [-p [op]priority]
    [-q destination] [-r y|n] [-s states] [-u user_list]
```

## DESCRIPTION

To select a set of batch jobs is to return the batch job_identifiers for each batch job that meets a list of selection criteria. A set of batch jobs is selected by a request to a batch server. The qselect utility is a user-accessible batch client that requests the selection of batch jobs.
Upon successful completion, the qselect utility shall have returned a list of zero or more batch job_identifiers that meet the criteria specified by the options and option-arguments presented to the utility.

The qselect utility shall select batch jobs by sending a Select Jobs Request to a batch server. The qselect utility shall not exit until the server replies to each request generated.

For each option presented to the qselect utility, the utility shall restrict the set of selected batch jobs as described in the OPTIONS section.

The qselect utility shall not restrict selection of batch jobs except by authorization and as required by the options presented to the utility.
When an option is specified with a mandatory or optional op component to the optionargument, then op shall specify a relation between the value of a certain batch job attribute and the value component of the option-argument. If an op is allowable on an option, then the description of the option letter indicates the op as either mandatory or optional. Acceptable strings for the op component, and the relation the string indicates, are shown in the following list:
.eq. The value represented by the attribute of the batch job is equal to the value represented by the option-argument.
.ge. The value represented by the attribute of the batch job is greater than or equal to the value represented by the option-argument.
.gt. The value represented by the attribute of the batch job is greater than the value represented by the option-argument.
.lt. The value represented by the attribute of the batch job is less than the value represented by the option-argument.
.le. The value represented by the attribute of the batch job is less than or equal to the value represented by the option-argument.
.ne. The value represented by the attribute of the batch job is not equal to the value represented by the option-argument.

## OPTIONS

The qselect utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-a [op]date_time
Restrict selection to a specific time, or a range of times.
The qselect utility shall select only batch jobs for which the value of the Execution_Time attribute is related to the Epoch equivalent of the local time expressed by the value of the date_time component of the option-argument in the manner indicated by the value of the op component of the option-argument.

The qselect utility shall accept a date_time component of the option-argument that conforms to the syntax of the time operand of the touch utility.
If the op component of the option-argument is not presented to the qselect utility, the utility shall select batch jobs for which the Execution_Time attribute is equal to the date_time component of the option-argument.
When comparing times, the qselect utility shall use the following definitions for the op component of the option-argument:
.eq. The time represented by value of the Execution_Time attribute of the batch job is equal to the time represented by the date_time component of the option-argument.
.ge. The time represented by value of the Execution_Time attribute of the batch job is after or equal to the time represented by the date_time component of the option-argument.
.gt. The time represented by value of the Execution_Time attribute of the batch job is after the time represented by the date time component of the optionargument.
.lt. The time represented by value of the Execution_Time attribute of the batch job is before the time represented by the date_time component of the option-argument.
.le. The time represented by value of the Execution_Time attribute of the batch job is before or equal to the time represented by the date_time component of the option-argument.
The time represented by value of the Execution_Time attribute of the batch job is notequal to the time represented by the date_time component of the option-argument.
The qselect utility shall accept the defined character strings for the op component of the option-argument.

## -A account_string

Restrict selection to the batch jobs charging a specified account.
The qselect utility shall select only batch jobs for which the value of the Account_Name attribute of the batch job matchs the value of the account_string option-argument.

The syntax of the account_string option-argument is unspecified.
-c [op]interval
Restrict selection to batch jobs within a range of checkpoint intervals.
The qselect utility shall select only batch jobs for which the value of the Checkpoint attribute relates to the value of the interval component of the option-argument in the manner indicated by the value of the op component of the option-argument.
If the op component of the option-argument is omitted, the qselect utility shall select batch jobs for which the value of the Checkpoint attribute is equal to the value of the
interval component of the option-argument.
When comparing checkpoint intervals, the qselect utility shall use the following definitions for the op component of the option-argument:
.eq. The value of the Checkpoint attribute of the batch job equals the value of the interval component of the option-argument.
.ge. The value of the Checkpoint attribute of the batch job is greater than or equal to the value of the interval component option-argument.
.gt. The value of the Checkpoint attribute of the batch job is greater than the value of the interval component option-argument.
.lt. The value of the Checkpoint attribute of the batch job is less than the value of the interval component option-argument.
.le. The value of the Checkpoint attribute of the batch job is less than or equal to the value of the interval component option-argument.
.ne. The value of the Checkpoint attribute of the batch job does not equal the value of the interval component option-argument.

The qselect utility shall accept the defined character strings for the op component of the option-argument.

The ordering relationship for the values of the interval option-argument is defined to be:

```
'n'.gt. 's'.gt. 'c=minutes' .ge. 'c'
```

When comparing Checkpoint attributes with an interval having the value of the single character ' $u$ ' , only equality or inequality are valid comparisons.
-h hold_list Restrict selection to batch jobs that have a specific type of hold.
The qselect utility shall select only batch jobs for which the value of the Hold_Types attribute matches the value of the hold_list option-argument.
The qselect -h option shall accept a value for the hold_list option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).
The qselect utility shall accept a value for the hold_list option-argument that is a string of one or more of the characters ' u ', ' s ', or ' $\mathrm{o}^{\prime}$ ', or the single character ' n '.
Each unique character in the hold_list option-argument of the qselect utility is defined as follows, each representing a different hold type:
u USER
s SYSTEM

- OPERATOR

If any of these characters are duplicated in the hold_list option-argument, the duplicates shall be ignored.
The qselect utility shall consider it an error if any hold type other than ' $n$ ' is combined with hold type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $u^{\prime}$, ' $s^{\prime}$, ' o ', or ' n ' within the hold_list option-argument. The qselect utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated
characters.
An implementation may define other hold types. The conformance document for an implementation shall describe any additional hold types, how they are specified, their internal behavior, and how they affect the behavior of the utility.
-1 resource_list
Restrict selection to batch jobs with specified resource limits and attributes.
The qselect utility shall accept a resource_list option-argument with the following syntax:
resource_name op value [,,resource_name op value, , ...]
When comparing resource values, the qselect utility shall use the following definitions for the op component of the option-argument:
.eq. The value of the resource of the same name in the Resource_List attribute of the batch job equals the value of the value component of the optionargument.
.ge. The value of the resource of the same name in the Resource_List attribute of the batch job is greater than or equal to the value of the value component of the option-argument.
.gt. The value of the resource of the same name in the Resource_List attribute of the batch job is greater than the value of the value component of the option-argument.
.lt. The value of the resource of the same name in the Resource_List attribute of the batch job is less than the value of the value component of the option-argument.
.ne. The value of the resource of the same name in the Resource_List attribute of the batch job does not equal the value of the value component of the option-argument.
.le. The value of the resource of the same name in the Resource_List attribute of the batch job is less than or equal to the value of the value component of the option-argument.
When comparing the limit of a Resource_List attribute with the value component of the option-argument, if the limit, the value, or both are non-numeric, only equality or inequality are valid comparisons.
The qselect utility shall select only batch jobs for which the values of the resource_names listed in the resource_list option-argument match the corresponding limits of the Resource_List attribute of the batch job.
Limits of resource_names present in the Resource_List attribute of the batch job that have no corresponding values in the resource_list option-argument shall not be considered when selecting batch jobs.
-N name Restrict selection to batch jobs with a specified name.
The qselect utility shall select only batch jobs for which the value of the Job_Name attribute matches the value of the name option-argument. The string specified in the name option-argument shall be passed, uninterpreted, to the server. This allows an implementation to match "wildcard" patterns against batch job names.
An implementation shall describe in the conformance document the format it supports for matching against the Job_Name attribute.

## -p [op]priority

Restrict selection to batch jobs of the specified priority or range of priorities.
The qselect utility shall select only batch jobs for which the value of the Priority attribute of the batch job relates to the value of the priority component of the option-argument in the manner indicated by the value of the op component of the option-argument.

If the op component of the option-argument is omitted, the qselect utility shall select batch jobs for which the value of the Priority attribute of the batch job is equal to the value of the priority component of the option-argument.

When comparing priority values, the qselect utility shall use the following definitions for the op component of the option-argument:
.eq. The value of the Priority attribute of the batch job equals the value of the priority component of the option-argument.
.ge. The value of the Priority attribute of the batch job is greater than or equal to the value of the priority component option-argument.
.gt. The value of the Priority attribute of the batch job is greater than the value of the priority component option-argument.
. lt . The value of the Priority attribute of the batch job is less than the value of the priority component option-argument.
.lt. The value of the Priority attribute of the batch job is less than or equal to the value of the priority component option-argument.
.ne. The value of the Priority attribute of the batch job does not equal the value of the priority component option-argument.
-q destination
Restrict selection to the specified batch queue or server, or both.
The qselect utility shall select only batch jobs that are located at the destination indicated by the value of the destination option-argument.

The destination defines a batch queue, a server, or a batch queue at a server.
The qselect utility shall accept an option-argument for the $-\mathbf{q}$ option that conforms to the syntax for a destination. If the $-\mathbf{q}$ option is not presented to the qselect utility, the utility shall select batch jobs from all batch queues at the default batch server.
If the option-argument describes only a batch queue, the qselect utility shall select only batch jobs from the batch queue of the specified name at the default batch server. The means by which qselect determines the default server is implementation-defined.
If the option-argument describes only a batch server, the qselect utility shall select batch jobs from all the batch queues at that batch server.

If the option-argument describes both a batch queue and a batch server, the qselect utility shall select only batch jobs from the specified batch queue at the specified server.
$-\mathbf{r} y \ln \quad$ Restrict selection to batch jobs with the specified rerunability status.
The qselect utility shall select only batch jobs for which the value of the Rerunable attribute of the batch job matches the value of the option-argument.

The qselect utility shall accept a value for the option-argument that consists of either the single character ' y ' or the single character ' n '. The character ' y '

| 31433 |  | represents the value TRUE, and the character ' n ' represents the value FALSE. |
| :---: | :---: | :---: |
| 31434 | -s states | Restrict selection to batch jobs in the specified states. |
| 31435 31436 |  | The qselect utility shall accept an option-argument that consists of any combination <br>  |
| 31437 31438 31439 |  | Conforming applications shall not repeat any character in the option-argument. The qselect utility shall permit the repetition of characters in the option-argument, but shall not assign additional meaning to repeated characters. |
| 31440 31441 |  | The qselect utility shall interpret the characters in the states option-argument as follows: |
| 31442 |  | e Represents the EXITING state. |
| 31443 |  | q Represents the QUEUED state. |
| 31444 |  | $r$ Represents the RUNNING state. |
| 31445 |  | $t$ Represents the TRANSITING state. |
| 31446 |  | h Represents the HELD state. |
| 31447 |  | w Represents the WAITING state. |
| 31448 |  | For each character in the states option-argument, the qselect utility shall select batch |
| 31449 |  | jobs in the corresponding state. |
| 31450 | -u user_list | Restrict selection to batch jobs owned by the specified user names. |
| 31451 |  | The qselect utility shall select only the batch jobs of those users specified in the |
| 31452 |  | user_list option-argument. |
| 31453 |  | The qselect utility shall accept a user-list option-argument that conforms to the |
| 31454 |  | following syntax: |
| 31455 |  | username[@host][,, username[@host], , ...] |
| 31456 |  | qselect utility shall accept only one user name that is missing a corresponding |
| 31457 |  | host name. The qselect utility shall accept only one user name per named host. |
| 31458 | OPERANDS |  |
| 31459 | None. |  |
| 31460 | STDIN | ( ${ }^{\text {c }}$ |
| 31461 | Not used. | \ $\gg$ |
| 31462 | INPUT FILES | - |
| 31463 | None. |  |
| 31464 | ENVIRONMENT VA | RIABLES |
| 31465 | The followin | g environment variables shall affect the execution of qselect: |
| 31466 | LANG | Provide a default value for the internationalization variables that are unset or null. |
| 31467 |  | (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, |
| 31468 |  | Internationalization Variables for the precedence of internationalization variables |
| 31469 |  | used to determine the values of locale categories.) |
| 31470 | LC_ALL | If set to a non-empty string value, override the values of all the other |
| 31471 |  | internationalization variables. |
| 31472 | LC_CTYPE | Determine the locale for the interpretation of sequences of bytes of text data as |
| 31473 |  | characters (for example, single-byte as opposed to multi-byte characters in |
| 31474 |  | arguments). |

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME Determine the login name of the user.
$T Z \quad$ Determine the timezone used to interpret the date-time option-argument. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

The qselect utility shall write zero or more batch job_identifiers to standard output.
The qselect utility shall separate the batch job_identifiers written to standard output by white space.
The qselect utility shall write batch job_identifiers in the following format:
sequence_number.server_name@server
STDERR
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

The following example shows how a user might use the qselect utility in conjunction with the qdel utility to delete all of his or her jobs in the queued state without affecting any jobs that are already running:
qdel $\$(q s e l e c t-s ~ q) ~$
or:
qselect -s q || xargs qdel

## RATIONALE

The qselect utility allows users to acquire a list of job identifiers that match user-specified selection criteria. The list of identifiers returned by the qselect utility conforms to the syntax of the batch job identifier list processed by a utility such as qmove, qdel, and qrls. The qselect utility is thus a powerful tool for causing another batch system utility to act upon a set of jobs that match a list of selection criteria.
The options of the qselect utility let the user apply a number of useful filters for selecting jobs. Each option further restricts the selection of jobs. Many of the selection options allow the specification of a relational operator. The FORTRAN-like syntax of the operator-that is,
". lt . "-was chosen rather than the C-like " $<=$ " meta-characters.
The -a option allows users to restrict the selected jobs to those that have been submitted (or altered) to wait until a particular time. The time period is determined by the argument of this option, which includes both a time and an operator-it is thus possible to select jobs waiting until a specific time, jobs waiting until after a certain time, or those waiting for a time before the specified time.

The -A option allows users to restrict the selected jobs to those that have been submitted (or altered) to charge a particular account.

The -c option allows users to restrict the selected jobs to those whose checkpointing interval falls within the specified range.
The -1 option allows users to select those jobs whose resource limits fall within the range indicated by the value of the option. For example, a user could select those jobs for which the CPU time limit is greater than two hours.
The - $\mathbf{N}$ option allows users to select jobs by job name. For instance, all the parts of a task that have been divided in parallel jobs might be given the same name, and thus manipulated as a group by means of this option.

The $-\mathbf{q}$ option allows users to select jobs in a specified queue.
The -r option allows users to select only those jobs with a specified rerun criteria. For instance, a user might select only those jobs that can be rerun for use with the qrerun utility.
The -s option allows users to select only those jobs that are in a certain state.
The $-\mathbf{u}$

## NAME

qsig - signal batch jobs

## SYNOPSIS

OB BE qsig [-s signal] job_identifier...

## DESCRIPTION

To signal a batch job is to send a signal to the session leader of the batch job. A batch job is signaled by sending a request to the batch server that manages the batch job. The qsig utility is a user-accessible batch client that requests the signaling of a batch job.
The qsig utility shall signal those batch jobs for which a batch job_identifier is presented to the utility. The qsig utility shall not signal any batch jobs whose batch job_identifiers are not presented to the utility.
The qsig utility shall signal batch jobs in the order in which the corresponding batch job_identifiers are presented to the utility. If the qsig utility fails to process a batch job_identifier successfully, the utility shall proceed to process the remaining batch job_identifiers, if any.
The qsig utility shall signal batch jobs by sending a Signal Job Request to the batch server that manages the batch job.
For each successfully processed batch job_identifier, the qsig utility shall have received a completion reply to each Signal Job Request sent to a batch server at the time the utility exits.

## OPTIONS

The qsig utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:
-s signal Define the signal to be sent to the batch job.
The qsig utility shall accept a signal option-argument that is either a symbolic signal name or an unsigned integer signal number (see the POSIX.1-1990 standard, Section 3.3.1.1). The qsig utility shall accept signal names for which the SIG prefix has been omitted.

If the signal option-argument is a signal name, the qsig utility shall send that name.
If the signal option-argument is a number, the qsig utility shall send the signal value represented by the number.
If the $-\mathbf{s}$ option is not presented to the qsig utility, the utility shall send the signal SIGTERM to each signaled batch job.

## OPERANDS

The qsig utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qsig:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LOGNAME Determine the login name of the user.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

An implementation of the qsig utility may write informative messages to standard output.

## STDERR

The standard error shall be used only for diagnostic messages.
OUTPUT FILES
None.

## EXTENDED DESCRIPTION

None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the qsig utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qsig utility waits to output the diagnostic message while attempting to locate the batch job on other servers is implementationdefined.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qsig utility allows users to signal batch jobs.
A user may be unable to signal a batch job with the kill utility of the operating system for a number of reasons. First, the process ID of the batch job may be unknown to the user. Second, the processes of the batch job may be on a remote node. However, by virtue of communication between batch nodes, the qsig utility can arrange for the signaling of a process.

Because a batch job that is not running cannot be signaled, and because the signal may not terminate the batch job, the qsig utility is not a substitute for the qdel utility.
The options of the qsig utility allow the user to specify the signal that is to be sent to the batch job.
The -s option allows users to specify a signal by name or by number, and thus override the default signal. The POSIX.1-1990 standard defines signals by both name and number.

The qsig utility is a new utility, vis-a-vis existing practice; it has been defined in this volume of IEEE Std 1003.1-200x in response to user-perceived shortcomings in existing practice.

## FUTURE DIRECTIONS

The qsig utility may be removed in a future version.

## SEE ALSO

Chapter 3 (on page 101), kill, qdel

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.

## Issue 6

The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.
Issue 7
The qsig utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
qstat - show status of batch jobs

## SYNOPSIS

OB BE

```
qstat [-f] job_identifier...
    qstat -Q [-f] destination...
    qstat -B [-f] server_name...
```

## DESCRIPTION

The status of a batch job, batch queue, or batch server is obtained by a request to the server. The qstat utility is a user-accessible batch client that requests the status of one or more batch jobs, batch queues, or servers, and writes the status information to standard output.
For each successfully processed batch job_identifier, the qstat utility shall display information about the corresponding batch job.

For each successfully processed destination, the qstat utility shall display information about the corresponding batch queue.

For each successfully processed server name, the qstat utility shall display information about the corresponding server.

The qstat utility shall acquire batch job status information by sending a Job Status Request to a batch server. The qstat utility shall acquire batch queue status information by sending a Queue Status Request to a batch server. The qstat utility shall acquire server status information by sending a Server Status Request to a batch server.

## OPTIONS

The qstat utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-f Specify that a full display is produced.
The minimum contents of a full display are specified in the STDOUT section.
Additional contents and format of a full display are implementation-defined.
-Q Specify that the operand is a destination.
The qstat utility shall display information about each batch queue at each destination identified as an operand.
-B Specify that the operand is a server name.
The qstat utility shall display information about each server identified as an operand.

## OPERANDS

If the - $\mathbf{Q}$ option is presented to the qstat utility, the utility shall accept one or more operands that conform to the syntax for a destination (see Section 3.3.2 (on page 123)).

If the -B option is presented to the qstat utility, the utility shall accept one or more server_name operands.
If neither the - $\mathbf{B}$ nor the $-\mathbf{Q}$ option is presented to the qstat utility, the utility shall accept one or more operands that conform to the syntax for a batch job_identifier (see Section 3.3.1 (on page 122)).

## STDIN

Not used.

## INPUT FILES

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qstat:
HOME Determine the pathname of the user's home directory.
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
LC_NUMERIC
Determine the locale for selecting the radix character used when writing floatingpoint formatted output.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If an operand presented to the qstat utility is a batch job_identifier and the -f option is not specified, the qstat utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch job_identifier
- The batch job name
- The Job_Owner attribute
- The CPU time used by the batch job
- The batch job state
- The batch job location

If an operand presented to the qstat utility is a batch job_identifier and the -f option is specified, the qstat utility shall display the following items for each success fully processed operand:

- The batch job_identifier
- The batch job name
- The Job_Owner attribute
- The execution user ID
- The CPU time used by the batch job
- The batch job state
- The batch job location
- Additional implementation-defined information, if any, about the batch job or batch queue

If an operand presented to the qstat utility is a destination, the $-\mathbf{Q}$ option is specified, and the $-\mathbf{f}$ option is not specified, the qstat utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch queue name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs in the batch queue
- The status of the batch queue
- For each state, the number of batch jobs in that state in the batch queue and the name of the state
- The type of batch queue (execution or routing)

If the operands presented to the qstat utility are destinations, the $-\mathbf{Q}$ option is specified, and the -f option is specified, the qstat utility shall display the following items for each successfully processed operand:

- The batch queue name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs in the batch queue
- The status of the batch queue
- For each state, the number of batch jobs in that state in the batch queue and the name of the state
- The type of batch queue (execution or routing)
- Additional implementation-defined information, if any, about the batch queue

If the operands presented to the qstat utility are batch server names, the -B option is specified, and the -f option is not specified, the qstat utility shall display the following items on a single line, in the stated order, with white space between each item, for each successfully processed operand:

- The batch server name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs managed by the batch server
- The status of the batch server
- For each state, the number of batch jobs in that state and the name of the state

If the operands presented to the qstat utility are server names, the -B option is specified, and the -f option is specified, the qstat utility shall display the following items for each successfully processed operand:

- The server name
- The maximum number of batch jobs that shall be run in the batch queue concurrently
- The total number of batch jobs managed by the server
- The status of the server
- For each state, the number of batch jobs in that state and the name of the state
- Additional implementation-defined information, if any, about the server

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

In addition to the default behavior, the gstat utility shall not be required to write a diagnostic message to standard error when the error reply received from a batch server indicates that the batch job_identifier does not exist on the server. Whether or not the qstat utility waits to output the diagnostic message while attempting to locate the batch job on other servers is implementation-defined.

## APPLICATION USAGE <br> None.

## EXAMPLES

None.

## RATIONALE

The qstat utility allows users to display the status of jobs and list the batch jobs in queues.
The operands of the qstat utility may be either job identifiers, queues (specified as destination identifiers), or batch server names. The $-\mathbf{Q}$ and $-\mathbf{B}$ options, or absence thereof, indicate the nature of the operands.
The other options of the qstat utility allow the user to control the amount of information displayed and the format in which it is displayed. Should a user wish to display the status of a set of jobs that match a selection criteria, the qselect utility may be used to acquire such a list.
The -f option allows users to request a "full" display in an implementation-defined format.
Historically, the qstat utility has been a part of the NQS and its derivatives, the existing practice on which it is based.

## FUTURE DIRECTIONS

The qstat utility may be removed in a future version.

## SEE ALSO

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
IEEE PASC Interpretation 1003.2 \#191 is applied, removing the following ENVIRONMENT VARIABLES listed as affecting qstat: COLUMNS, LINES, LOGNAME, TERM, and TZ.

The LC_TIME entry is also removed from the ENVIRONMENT VARIABLES section.
Issue 7
The qstat utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
qsub - submit a script

## SYNOPSIS

```
OB BE qsub [-a date_time] [-A account_string] [-c interval]
    [-C directive_prefix] [-e path_name] [-h] [-j join_list]
        [-k keep_list] [-m mail_options] [-M mail_list] [-N name]
        [-o path_name] [-p priority] [-q destination] [-r y|n]
        [-S path_name_list] [-u user_list] [-v variable_list] [-V]
        [-z] [script]
```

## DESCRIPTION

To submit a script is to create a batch job that executes the script. A script is submitted by a request to a batch server. The qsub utility is a user-accessible batch client that submits a script.
Upon successful completion, the qsub utility shall have created a batch job that will execute the submitted script.
The qsub utility shall submit a script by sending a Queue Job Request to a batch server.
The qsub utility shall place the value of the following environment variables in the Variable_List attribute of the batch job: HOME, LANG, LOGNAME, PATH, MAIL, SHELL, and TZ. The name of the environment variable shall be the current name prefixed with the string PBS_O_.
Note: If the current value of the $H O M E$ variable in the environment space of the qsub utility is $/ \mathbf{a a} / \mathbf{b b} / \mathbf{c c}$, then qsub shall place PBS_O_HOME=/aa/bb/cc in the Variable_List attribute of the batch job.

In addition to the variables described above, the qsub utility shall add the following variables with the indicated values to the variable list:

PBS_O_WORKDIR The absolute path of the current working directory of the qsub utility process.
PBS_O_HOST The name of the host on which the qsub utility is running.

## OPTIONS

The qsub utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported by the implementation:
-a date_time Define the time at which a batch job becomes eligible for execution.
The qsub utility shall accept an option-argument that conforms to the syntax of the time operand of the touch utility.

Table 4-18 Environment Variable Values (Utilities)

| Variable Name | Value at qsub Time |
| :--- | :--- |
| PBS_O_HOME | HOME |
| PBS_O_HOST | Client host name |
| PBS_O_LANG | LANG |
| PBS_O_LOGNAME | LOGNAME |
| PBS_O_PATH | PATH |
| PBS_O_MAIL | MAIL |
| PBS_O_SHELL | SHELL |
| PBS_O_TZ | TZ |
| PBS_O_WORKDIR | Current working directory |

Note: The server that initiates execution of the batch job will add other variables to the batch job's environment; see Section 3.2.2.1 (on page 106).

The qsub utility shall set the Execution_Time attribute of the batch job to the number of seconds since the Epoch that is equivalent to the local time expressed by the value of the date_time option-argument. The Epoch is defined in the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.149, Epoch.
If the -a option is not presented to the qsub utility, the utility shall set the Execution_Time attribute of the batch job to a time (number of seconds since the Epoch) that is earlier than the time at which the utility exits.
-A account_string
Define the account to which the resource consumption of the batch job should be charged.
The syntax of the account_string option-argument is unspecified.
The qsub utility shall set the Account_Name attribute of the batch job to the value of the account_string option-argument.
If the -A option is not presented to the qsub utility, the utility shall omit the Account_Name attribute from the attributes of the batch job.
-c interval Define whether the batch job should be checkpointed, and if so, how often.
The qsub utility shall accept a value for the interval option-argument that is one of the following:
n No checkpointing shall be performed on the batch job (NO_CHECKPOINT).
Checkpointing shall be performed only when the batch server is shut down (CHECKPOINT_AT_SHUTDOWN).
c Automatic periodic checkpointing shall be performed at the Minimum_Cpu_Interval attribute of the batch queue, in units of CPU minutes (CHECKPOINT_AT_MIN_CPU_INTERVAL).
$\mathrm{c}=$ minutes $\quad$ Automatic periodic checkpointing shall be performed every minutes of CPU time, or every Minimum_Cpu_Interval minutes, whichever is greater. The minutes argument shall conform to the syntax for unsigned integers and shall be greater than zero.
The qsub utility shall set the Checkpoint attribute of the batch job to the value of the interval option-argument.

If the -c option is not presented to the qsub utility, the utility shall set the Checkpoint attribute of the batch job to the single character ' u ' (CHECKPOINT_UNSPECIFIED).
-C directive_prefix
Define the prefix that declares a directive to the qsub utility within the script.
The directive_prefix is not a batch job attribute; it affects the behavior of the qsub utility.

If the -C option is presented to the qsub utility, and the value of the directive_prefix option-argument is the null string, the utility shall not scan the script file for directives. If the -C option is not presented to the qsub utility, then the value of the PBS_DPREFIX environment variable is used. If the environment variable is not defined, then \#PBS encoded in the portable character set is the default.
-e path_name
Define the path to be used for the standard error stream of the batch job.
The qsub utility shall accept a path_name option-argument which can be preceded by a host name element of the form hostname:-

If the path_name option-argument constitutes an absolute pathname, the qsub utility shall set the Error_Path attribute of the batch job to the value of the path_name option-argument.

If the path_name option-argument constitutes a relative pathname and no host name element is specified, the qsub utility shall set the Error_Path attribute of the batch job to the value of the absolute pathname derived by expanding the path_name option-argument relative to the current directory of the process executing qsub.
If the path_name option-argument constitutes a relative pathname and a host name element is specified, the gsub utility shall set the Error_Path attribute of the batch job to the value of the path_name option-argument without expansion. The host name element shall be included.

If the path_name option-argument does not include a host name element, the qsub utility shall prefix the pathname with hostname:, where hostname is the name of the host upon which the qsub utility is being executed.

If the -e option is not presented to the qsub utility, the utility shall set the Error_Path attribute of the batch job to the host name and path of the current directory of the submitting process and the default filename.
The default filename for standard error has the following format:
job_name. esequence_number
-h Specify that a USER hold is applied to the batch job.
The qsub utility shall set the value of the Hold_Types attribute of the batch job to the value USER.

If the -h option is not presented to the qsub utility, the utility shall set the Hold_Types attribute of the batch job to the value NO_HOLD.
-j join_list Define which streams of the batch job are to be merged. The qsub -j option shall accept a value for the join_list option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).
The qsub utility shall accept a join_list option-argument that consists of one or more
of the characters ' $\mathrm{e}^{\prime}$ and ' $\mathrm{o}^{\prime}$, or the single character ' n '.
All of the other batch job output streams specified will be merged into the output stream represented by the character listed first in the join_list option-argument.
For each unique character in the join_list option-argument, the qsub utility shall add a value to the Join_Path attribute of the batch job as follows, each representing a different batch job stream to join:
e The standard error of the batch job (JOIN_STD_ERROR).

- The standard output of the batch job (JOIN_STD_OUTPUT).

An existing Join_Path attribute can be cleared by the following join type:
n NO_JOIN
If ' $n$ ' is specified, then no files are joined. The qsub utility shall consider it an error if any join type other than ' $n$ ' is combined with join type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $\mathrm{e}^{\prime}, \mathrm{o} \mathrm{o}^{\prime}$, or ' n ' within the join_list option-argument. The qsub utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other join types. The conformance document for an implementation shall describe any additional batch job streams, how they are specified, their internal behavior, and how they affect the behavior of the utility.
If the $-\mathbf{j}$ option is not presented to the gsub utility, the utility shall set the value of the Join_Path attribute of the batch job to NO_JOIN.
-k keep_list Define which output of the batch job to retain on the execution host.
The qsub $-\mathbf{k}$ option shall accept a value for the keep_list option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The qsub utility shall accept a keep_list option-argument that consists of one or more of the characters ' e ' and ' o ', or the single character ' n '.
For each unique character in the keep_list option-argument, the qsub utility shall add a value to the Keep_Files attribute of the batch job as follows, each representing a different batch job stream to keep:
e The standard error of the batch job (KEEP_STD_ERROR).

- The standard output of the batch job (KEEP_STD_OUTPUT).

If both ' $e$ ' and ' $o$ ' are specified, then both files are retained. An existing Keep_Files attribute can be cleared by the following keep type:

## n NO_KEEP

If ' $n$ ' is specified, then no files are retained. The qsub utility shall consider it an error if any keep type other than ' $n$ ' is combined with keep type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $\mathrm{e}^{\prime}, \mathrm{\prime} \mathrm{o}^{\prime}$, or ' n ' within the keep_list option-argument. The qsub utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters.

An implementation may define other keep types. The conformance document for an implementation shall describe any additional keep types, how they are specified, their internal behavior, and how they affect the behavior of the utility. If
the $-\mathbf{k}$ option is not presented to the qsub utility, the utility shall set the Keep_Files attribute of the batch job to the value NO_KEEP.

## -m mail_options

Define the points in the execution of the batch job at which the batch server that manages the batch job shall send mail about a change in the state of the batch job.

The qsub-m option shall accept a value for the mail_options option-argument that is a string of alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set).

The qsub utility shall accept a value for the mail_options option-argument that is a string of one or more of the characters ' $e^{\prime},{ }^{\prime} b^{\prime}$ ' and ' $\mathrm{a}^{\prime}$ ', or the single character ' n '.

For each unique character in the mail_options option-argument, the qsub utility shall add a value to the Mail_Users attribute of the batch job as follows, each representing a different time during the life of a batch job at which to send mail:
e MAIL_AT_EXIT
b MAIL_AT_BEGINNING
a MAIL_AT_ABORT
If any of these characters are duplicated in the mail_options option-argument, the duplicates shall be ignored.
An existing Mail_Points attribute can be cleared by the following mail type:
n NO_MAIL
If ' $n$ ' is specified, then mail is not sent. The qsub utility shall consider it an error if any mail type other than ' $n$ ' is combined with mail type ' $n$ '.
Strictly conforming applications shall not repeat any of the characters ' $e^{\prime},{ }^{\prime} b^{\prime}$, ' $\mathrm{a}^{\prime}$, or ' n ' within the mail_options option-argument.

The qsub utility shall permit the repetition of characters, but shall not assign additional meaning to the repeated characters. An implementation may define other mail types. The conformance document for an implementation shall describe any additional mail types, how they are specified, their internal behavior, and how they affect the behavior of the utility.
If the $-\mathbf{m}$ option is not presented to the qsub utility, the utility shall set the Mail_Points attribute to the value MAIL_AT_ABORT.
-M mail_list Define the list of users to which a batch server that executes the batch job shall send mail, if the server sends mail about the batch job.
The syntax of the mail_list option-argument is unspecified.
If the implementation of the qsub utility uses a name service to locate users, the utility should accept the syntax used by the name service.

If the implementation of the qsub utility does not use a name service to locate users, the implementation should accept the following syntax for user names:
mail_address[,,mail_address, , ...]
The interpretation of mail_address is implementation-defined.
The qsub utility shall set the Mail_Users attribute of the batch job to the value of the mail_list option-argument.

If the $\mathbf{- M}$ option is not presented to the $q s u b$ utility, the utility shall place only the user name and host name for the current process in the Mail_Users attribute of the batch job.
-N name Define the name of the batch job.
The qsub $\mathbf{- N}$ option shall accept a value for the name option-argument that is a string of up to 15 alphanumeric characters in the portable character set (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 6.1, Portable Character Set) where the first character is alphabetic.

The qsub utility shall set the value of the Job_Name attribute of the batch job to the value of the name option-argument.

If the $\mathbf{- N}$ option is not presented to the qsub utility, the utility shall set the Job_Name attribute of the batch job to the name of the script argument from which the directory specification if any, has been removed.
If the $-\mathbf{N}$ option is not presented to the qsub utility, and the script is read from standard input, the utility shall set the Job_Name attribute of the batch job to the value STDIN.

- o path_name

Define the path for the standard output of the batch job.
The qsub utility shall accept a path_name option-argument that conforms to the syntax of the path_name element defined in the System Interfaces volume of IEEE Std 1003.1-200x, which can be preceded by a host name element of the form hostname:.

If the path_name option-argument constitutes an absolute pathname, the qsub utility shall set the Output_Path attribute of the batch job to the value of the path_name option-argument without expansion.
If the path $\_$name option-argument constitutes a relative pathname and no host name element is specified, the qsub utility shall set the Output_Path attribute of the batch job to the pathname derived by expanding the value of the path_name optionargument relative to the current directory of the process executing the qsub.

If the path_name option-argument constitutes a relative pathname and a host name element is specified, the qsub utility shall set the Output_Path attribute of the batch job to the value of the path_name option-argument without expansion.

If the path_name option-argument does not specify a host name element, the qsub utility shall prefix the pathname with hostname:, where hostname is the name of the host upon which the qsub utility is executing.
If the -o option is not presented to the qsub utility, the utility shall set the Output_Path attribute of the batch job to the host name and path of the current directory of the submitting process and the default filename.

The default filename for standard output has the following format:
job_name.osequence_number
-p priority Define the priority the batch job should have relative to other batch jobs owned by the batch server.

The qsub utility shall set the Priority attribute of the batch job to the value of the priority option-argument.
If the -p option is not presented to the qsub utility, the value of the Priority attribute is implementation-defined.

```
The qsub utility shall accept a value for the priority option-argument that conforms to the syntax for signed decimal integers, and which is not less than -1024 and not greater than 1023.
-q destination
Define the destination of the batch job.
The destination is not a batch job attribute; it determines the batch server, and possibly the batch queue, to which the qsub utility batch queues the batch job.
The qsub utility shall submit the script to the batch server named by the destination option-argument or the server that owns the batch queue named in the destination option-argument.
The qsub utility shall accept an option-argument for the \(-\mathbf{q}\) option that conforms to the syntax for a destination (see Section 3.3.2 (on page 123)).
If the \(-\mathbf{q}\) option is not presented to the \(q s u b\) utility, the \(q s u b\) utility shall submit the batch job to the default destination. The mechanism for determining the default destination is implementation-defined.
\(-\mathbf{r} y \mid n \quad\) Define whether the batch job is rerunnable.
If the value of the option-argument is \(y\), the \(q s u b\) utility shall set the Rerunable attribute of the batch job to TRUE.
If the value of the option-argument is \(n\), the \(q s u b\) utility shall set the Rerunable attribute of the batch job to FALSE.
If the \(-\mathbf{r}\) option is not presented to the qsub utility, the utility shall set the Rerunable attribute of the batch job to TRUE.
-S path_name_list
Define the pathname to the shell under which the batch job is to execute.
The qsub utility shall accept a path_name_list option-argument that conforms to the following syntax:
pathname[@host][, , pathname[@host], , ...]
The qsub utility shall allow only one pathname for a given host name. The qsub utility shall allow only one pathname that is missing a corresponding host name.
The qsub utility shall add a value to the Shell_Path_List attribute of the batch job for each entry in the path_name \(\quad\) list option-argument.
If the \(-S\) option is not presented to the qsub utility, the utility shall set the Shell_Path_List attribute of the batch job to the null string.
The conformance document for an implementation shall describe the mechanism used to set the default shell and determine the current value of the default shell. An implementation shall provide a means for the installation to set the default shell to the login shell of the user under which the batch job is to execute. See Section 3.3.3 for a means of removing keyword=value (and value@keyword) pairs and other general rules for list-oriented batch job attributes.
-u user_list Define the user name under which the batch job is to execute.
The qsub utility shall accept a user_list option-argument that conforms to the following syntax:
username[@host][, , username[@host], , ...]
The qsub utility shall accept only one user name that is missing a corresponding
```

host name. The qsub utility shall accept only one user name per named host.
The qsub utility shall add a value to the User_List attribute of the batch job for each entry in the user_list option-argument.
If the -u option is not presented to the qsub utility, the utility shall set the User_List attribute of the batch job to the user name from which the utility is executing. See Section 3.3.3 for a means of removing keyword=value (and value@keyword) pairs and other general rules for list-oriented batch job attributes.
-v variable_list
Add to the list of variables that are exported to the session leader of the batch job.
A variable_list is a set of strings of either the form <variable> or <variable=value>, delimited by commas.
If the $-\mathbf{v}$ option is presented to the $q s u b$ utility, the utility shall also add, to the environment Variable_List attribute of the batch job, every variable named in the environment variable_list option-argument and, optionally, values of specified variables.

If a value is not provided on the command line, the qsub utility shall set the value of each variable in the environment Variable_List attribute of the batch job to the value of the corresponding environment variable for the process in which the utility is executing; see Table 4-18 (on page 808).
A conforming application shall not repeat a variable in the environment variable_list option-argument.
The qsub utility shall not repeat a variable in the environment Variable_List attribute of the batch job. See Section 3.3.3 for a means of removing keyword=value (and value@keyword) pairs and other general rules for list-oriented batch job attributes.
-V Specify that all of the environment variables of the process are exported to the context of the batch job.
The qsub utility shall place every environment variable in the process in which the utility is executing in the list and shall set the value of each variable in the attribute to the value of that variable in the process.
Specify that the utility does not write the batch job_identifier of the created batch job to standard output.

If the $-\mathbf{z}$ option is presented to the qsub utility, the utility shall not write the batch job_identifier of the created batch job to standard output.
If the $-\mathbf{z}$ option is not presented to the qsub utility, the utility shall write the identifier of the created batch job to standard output.

## OPERANDS

The qsub utility shall accept a script operand that indicates the path to the script of the batch job.
If the script operand is not presented to the qsub utility, or if the operand is the single-character string ${ }^{\prime}-{ }^{\prime}$, the utility shall read the script from standard input.

If the script represents a partial path, the qsub utility shall expand the path relative to the current directory of the process executing the utility.

## STDIN

The qsub utility reads the script of the batch job from standard input if the script operand is omitted or is the single character ${ }^{\prime}-{ }^{\prime}$.

## INPUT FILES

In addition to binding the file indicated by the script operand to the batch job, the qsub utility reads the script file and acts on directives in the script.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of qsub:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

LOGNAME Determine the login name of the user.
PBS_DPREFIX
Determine the default prefix for directives within the script.
SHELL Determine the pathname of the preferred command language interpreter of the user.
$T Z \quad$ Determine the timezone used to interpret the date-time option-argument. If $T Z$ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Once created, a batch job exists until it exits, aborts, or is deleted.
After a batch job is created by the qsub utility, batch servers might route, execute, modify, or delete the batch job.

## STDOUT

The qsub utility writes the batch job-identifier assigned to the batch job to standard output, unless the $-\mathbf{z}$ option is specified.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## Script Preservation

The qsub utility shall make the script available to the server executing the batch job in such a way that the server executes the script as it exists at the time of submission.
The qsub utility can send a copy of the script to the server with the Queue Job Request or store a temporary copy of the script in a location specified to the server.

## Option Specification

A script can contain directives to the $q s u b$ utility.
The $q s u b$ utility shall scan the lines of the script for directives, skipping blank lines, until the first line that begins with a string other than the directive string; if directives occur on subsequent lines, the utility shall ignore those directives.

Lines are separated by a <newline>. If the first line of the script begins with "\#!" or a colon $\left(^{\prime}:^{\prime}\right)$, then it is skipped. The $q s u b$ utility shall process a line in the script as a directive if and only if the string of characters from the first non-white-space character on the line until the first <space> or <tab> on the line match the directive prefix. If a line in the script contains a directive and the final characters of the line are backslash ( ${ }^{\prime} \backslash^{\prime}$ ) and <newline>, then the next line shall be interpreted as a continuation of that directive.
The qsub utility shall process the options and option-arguments contained on the directive prefix line using the same syntax as if the options were input on the qsub utility.
The qsub utility shall continue to process a directive prefix line until after a <newline> is encountered. An implementation may ignore lines which, according to the syntax of the shell that will interpret the script, are comments. An implementation shall describe in the conformance document the format of any shell comments that it will recognize.

If an option is present in both a directive and the arguments to the qsub utility, the utility shall ignore the option and the corresponding option-argument, if any, in the directive.

If an option that is present in the directive is not present in the arguments to the qsub utility, the utility shall process the option and the option-argument, if any.
In order of preference, the qsub utility shall select the directive prefix from one of the following sources:

- If the -C option is presented to the utility, the value of the directive_prefix option-argument
- If the environment variable PBS_DPREFIX is defined, the value of that variable
- The four-character string "\#PBS" encoded in the portable character set

If the $-\mathbf{C}$ option is present in the script file it shall be ignored.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

The qsub utility allows users to create a batch job that will process the script specified as the operand of the utility.
The options of the qsub utility allow users to control many aspects of the queuing and execution of a batch job.
The -a option allows users to designate the time after which the batch job will become eligible to run. By specifying an execution time, users can take advantage of resources at off-peak hours,
synchronize jobs with chronologically predictable events, and perhaps take advantage of offpeak pricing of computing time. For these reasons and others, a timing option is existing practice on the part of almost every batch system, including NQS.
The - A option allows users to specify the account that will be charged for the batch job. Support for account is not mandatory for conforming batch servers.

The -C option allows users to prescribe the prefix for directives within the script file. The default prefix "\#PBS" may be inappropriate if the script will be interpreted with an alternate shell, as specified by the $-\mathbf{S}$ option.
The -c option allows users to establish the checkpointing interval for their jobs. A checkpointing system, which is not defined by this volume of IEEE Std 1003.1-200x, allows recovery of a batch job at the most recent checkpoint in the event of a crash. Checkpointing is typically used for jobs that consume expensive computing time or must meet a critical schedule. Users should be allowed to make the tradeoff between the overhead of checkpointing and the risk to the timely completion of the batch job; therefore, this volume of IEEE Std 1003.1-200x provides the checkpointing interval option. Support for checkpointing is optional for batch servers.
The -e option allows users to redirect the standard error streams of their jobs to a non-default path. For example, if the submitted script generally produces a great deal of useless error output, a user might redirect the standard error output to the null device. Or, if the file system holding the default location (the home directory of the user) has too little free space, the user might redirect the standard error stream to a file in another file system.

The -h option allows users to create a batch job that is held until explicitly released. The ability to create a held job is useful when some external event must complete before the batch job can execute. For example, the user might submit a held job and release it when the system load has dropped.
The $-\mathbf{j}$ option allows users to merge the standard error of a batch job into its standard output stream, which has the advantage of showing the sequential relationship between output and error messages.

The $-\mathbf{m}$ option allows users to designate those points in the execution of a batch job at which mail will be sent to the submitting user, or to the account(s) indicated by the $-\mathbf{M}$ option. By requesting mail notification at points of interest in the life of a job, the submitting user, or other designated users, can track the progress of a batch job.

The $\mathbf{- N}$ option allows users to associate a name with the batch job. The job name in no way affects the processing of the batch job, but rather serves as a mnemonic handle for users. For example, the batch job name can help the user distinguish between multiple jobs listed by the qstat utility.
The -o option allows users to redirect the standard output stream. A user might, for example, wish to redirect to the null device the standard output stream of a job that produces copious yet superfluous output.
The - $\mathbf{P}$ option allows users to designate the relative priority of a batch job for selection from a queue.

The $-\mathbf{q}$ option allows users to specify an initial queue for the batch job. If the user specifies a routing queue, the batch server routes the batch job to another queue for execution or further routing. If the user specifies a non-routing queue, the batch server of the queue eventually executes the batch job.
The -r option allows users to control whether the submitted job will be rerun if the controlling batch node fails during execution of the batch job. The -r option likewise allows users to indicate whether or not the batch job is eligible to be rerun by the qrerun utility. Some jobs cannot be correctly rerun because of changes they make in the state of databases or other aspects of
their environment. This volume of IEEE Std 1003.1-200x specifies that the default, if the -r option is not presented to the utility, will be that the batch job cannot be rerun, since the result of rerunning a non-rerunnable job might be catastrophic.
The - S option allows users to specify the program (usually a shell) that will be invoked to process the script of the batch job. This option has been modified to allow a list of shell names and locations associated with different hosts.

The -u option is useful when the submitting user is authorized to use more than one account on a given host, in which case the -u option allows the user to select from among those accounts. The option-argument is a list of user-host pairs, so that the submitting user can provide different user identifiers for different nodes in the event the batch job is routed. The $-\mathbf{u}$ option provides a lot of flexibility to accommodate sites with complex account structures. Users that have the same user identifier on all the hosts they are authorized to use will not need to use the -u option.
The -V option allows users to export all their current environment variables, as of the time the batch job is submitted, to the context of the processes of the batch job.
The -v option allows users to export specific environment variables from their current process to the processes of the batch job.

The $-\mathbf{z}$ option allows users to suppress the writing of the batch job identifier to standard output. The $-\mathbf{z}$ option is an existing NQS practice that has been standardized.

Historically, the qsub utility has served the batch job-submission function in the NQS system, the existing practice on which it is based. Some changes and additions have been made to the qsub utility in this volume of IEEE Std 1003.1-200x, vis-a-vis NQS, as a result of the growing pool of experience with distributed batch systems.
The set of features of the qsub utility as defined in this volume of IEEE Std 1003.1-200x appears to incorporate all the common existing practice on potentially conforming platforms.

## FUTURE DIRECTIONS

The qsub utility may be removed in a future version.

## SEE ALSO

Chapter 3 (on page 101), qrerun, qstat, touch

## CHANGE HISTORY

Derived from IEEE Std 1003.2d-1994.
Issue 6
The -1 option has been removed as there is no portable description of the resources that are allowed or required by the batch job.
Issue 7
The qsub utility is marked obsolescent.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
read - read a line from standard input

## SYNOPSIS

read [-r] var...

## DESCRIPTION

The read utility shall read a single line from standard input.
By default, unless the $-\mathbf{r}$ option is specified, backslash ( ${ }^{\prime} \backslash^{\prime}$ ) shall act as an escape character, as described in Section 2.2.1 (on page 30). If standard input is a terminal device and the invoking shell is interactive, read shall prompt for a continuation line when:

- The shell reads an input line ending with a backslash <newline>, unless the $-\mathbf{r}$ option is specified.
- A here-document is not terminated after a <newline> is entered.

The terminating <newline> (if any) shall be removed from the input and the results shall be split into fields as in the shell for the results of parameter expansion (see Section 2.6 .5 (on page 42)); the first field shall be assigned to the first variable var, the second field to the second variable var, and so on. If there are fewer fields than there are var operands, the remaining vars shall be set to empty strings. If there are fewer vars than fields, the last var shall be set to a value comprising the following elements:

- The field that corresponds to the last var in the normal assignment sequence described above
- The delimiter(s) that follow the field corresponding to the last var
- The remaining fields and their delimiters, with trailing IFS white space ignored

The setting of variables specified by the var operands shall affect the current shell execution environment; see Section 2.12 (on page 61). If it is called in a subshell or separate utility execution environment, such as one of the following:
(read foo)
nohup read...
find . -exec read ... \;
it shall not affect the shell variables in the caller's environment.

## OPTIONS

The read utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option is supported:
-r Do not treat a backslash character in any special way. Consider each backslash to be part of the input line.

## OPERANDS

The following operand shall be supported:
var The name of an existing or nonexisting shell variable.

## STDIN

The standard input shall be a text file.

## INPUT FILES

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of read:
IFS Determine the internal field separators used to delimit fields; see Section 2.5.3 (on page 34).

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PS2 Provide the prompt string that an interactive shell shall write to standard error when a line ending with a backslash <newline> is read and the $-\mathbf{r}$ option was not specified, or if a here-document is not terminated after a <newline> is entered.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.
STDERR
The standard error shall be used for diagnostic messages and prompts for continued input.
OUTPUT FILES
None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 End-of-file was detected or an error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The -r option is included to enable read to subsume the purpose of the line utility, which is not included in IEEE Std 1003.1-200x.

## EXAMPLES

The following command:

```
while read -r xx yy
do
    printf "%s %s\n" "$yy" "$xx"
done < input_file
```

prints a file with the first field of each line moved to the end of the line.

## RATIONALE

The read utility historically has been a shell built-in. It was separated off into its own utility to take advantage of the richer description of functionality introduced by this volume of IEEE Std 1003.1-200x.

Since read affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(read foo)
nohup read ...
find . -exec read ... \;
```

it does not affect the shell variables in the environment of the caller.
Although the standard input is required to be a text file, and therefore will always end with a <newline> (unless it is an empty file), the processing of continuation lines when the -r option is not used can result in the input not ending with a <newline>. This occurs if the last line of the input file ends with backslash <newline>. It is for this reason that "if any" is used in "The terminating <newline> (if any) shall be removed from the input" in the description. It is not a relaxation of the requirement for standard input to be a text file.

## FUTURE DIRECTIONS

None.
SEE ALSO
Chapter 2

## CHANGE HISTORY

First released in Issue 2.
Issue 7
SD5-XCU-ERN-126 is applied, clarifying that input lines end with a <newline>.

NAME
renice - set nice values of running processes

## SYNOPSIS

```
renice -n increment [-g |-p |-u] ID...
```

## DESCRIPTION

The renice utility shall request that the nice values (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.239, Nice Value) of one or more running processes be changed. By default, the applicable processes are specified by their process IDs. When a process group is specified (see $-\mathbf{g}$ ), the request shall apply to all processes in the process group.
The nice value shall be bounded in an implementation-defined manner. If the requested increment would raise or lower the nice value of the executed utility beyond implementationdefined limits, then the limit whose value was exceeded shall be used.

When a user is reniced, the request applies to all processes whose saved set-user-ID matches the user ID corresponding to the user.

Regardless of which options are supplied or any other factor, renice shall not alter the nice values of any process unless the user requesting such a change has appropriate privileges to do so for the specified process. If the user lacks appropriate privileges to perform the requested action, the utility shall return an error status.
The saved set-user-ID of the user's process shall be checked instead of its effective user ID when renice attempts to determine the user ID of the process in order to determine whether the user has appropriate privileges.

## OPTIONS

The renice utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for Guideline 9.

The following options shall be supported:

- $\mathbf{g}$ Interpret the following operands as unsigned decimal integer process group IDs.
-n increment Specify how the nice value of the specified process or processes is to be adjusted.
The increment option-argument is a positive or negative decimal integer that shall be used to modify the nice value of the specified process or processes.
Positive increment values shall cause a lower nice value. Negative increment values may require appropriate privileges and shall cause a higher nice value.
$-\mathbf{p} \quad$ Interpret the following operands as unsigned decimal integer process IDs. The $-\mathbf{p}$ option is the default if no options are specified.
-u Interpret the following operands as users. If a user exists with a user name equal to the operand, then the user ID of that user is used in further processing. Otherwise, if the operand represents an unsigned decimal integer, it shall be used as the numeric user ID of the user.

## OPERANDS

The following operands shall be supported:
ID A process ID, process group ID, or user name/user ID, depending on the option selected.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of renice:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

1. Adjust the nice value so that process IDs 987 and 32 would have a lower nice value:
renice -n 5-p 98732
2. Adjust the nice value so that group IDs 324 and 76 would have a higher nice value, if the user has the appropriate privileges to do so:
renice $-\mathrm{n}-4$-g 32476
3. Adjust the nice value so that numeric user ID 8 and user sas would have a lower nice value:
```
renice -n 4 -u 8 sas
```

Useful nice value increments on historical systems include 19 or 20 (the affected processes run only when nothing else in the system attempts to run) and any negative number (to make processes run faster).

## RATIONALE

The gid, pid, and user specifications do not fit either the definition of operand or optionargument. However, for clarity, they have been included in the OPTIONS section, rather than the OPERANDS section.

The definition of nice value is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions such as the realtime priorities in the System Interfaces volume of IEEE Std 1003.1-200x make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the nicerelated features to affect all processes on the system, others to affect just the general time-sharing activities implied by this volume of IEEE Std 1003.1-200x, and others may have no effect at all. Because of the use of "implementation-defined" in nice and renice, a wide range of implementation strategies are possible.

Originally, this utility was written in the historical manner, using the term "nice value". This was always a point of concern with users because it was never intuitively obvious what this meant. With a newer version of renice, which used the term "system scheduling priority", it was hoped that novice users could better understand what this utility was meant to do. Also, it would be easier to document what the utility was meant to do. Unfortunately, the addition of the POSIX realtime scheduling capabilities introduced the concepts of process and thread scheduling priorities that were totally unaffected by the nice/renice utilities or the nice ()/setpriority () functions. Continuing to use the term "system scheduling priority" would have incorrectly suggested that these utilities and functions were indeed affecting these realtime priorities. It was decided to revert to the historical term "nice value" to reference this unrelated process attribute.

Although this utility has use by system administrators (and in fact appears in the system administration portion of the BSD documentation), the standard developers considered that it was very useful for individual end users to control their own processes.

Earlier versions of this standard allowed the following forms in the SYNOPSIS:

```
renice nice_value[-p] pid...[-g gid...][-p pid...][-u user...]
renice nice_value -g gid...[-g gid...]-p pid...][-u user...]
renice nice_value -u user...[-g gid...]-p pid...][-u user...]
```

These forma are no longer specified by this standard but may be present in some implementations.

## FUTURE DIRECTIONS

## None.

## CHANGE HISTORY

First released in Issue 4.

## Issue 5

In the SYNOPSIS, an ellipsis is added to the $-\mathbf{u}$ option in all three obsolescent forms.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
The obsolescent forms of the SYNOPSIS are removed.
Text previously conditional on POSIX_SAVED_IDS is mandatory in this issue. This is a FIPS requirement.

Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.
The renice utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
rm - remove directory entries

## SYNOPSIS

rm [-fiRr] file...

## DESCRIPTION

The $r m$ utility shall remove the directory entry specified by each file argument.
If either of the files dot or dot-dot are specified as the basename portion of an operand (that is, the final pathname component) or if an operand resolves to the root directory, $r m$ shall write a diagnostic message to standard error and do nothing more with such operands.

For each file the following steps shall be taken:

1. If the file does not exist:
a. If the -f option is not specified, $r m$ shall write a diagnostic message to standard error.
b. Go on to any remaining files.
2. If file is of type directory, the following steps shall be taken:
a. If neither the $-\mathbf{R}$ option nor the $-\mathbf{r}$ option is specified, $r m$ shall write a diagnostic message to standard error, do nothing more with file, and go on to any remaining files.
b. If the -f option is not specified, and either the permissions of file do not permit writing and the standard input is a terminal or the $-\mathbf{i}$ option is specified, rm shall write a prompt to standard error and read a line from the standard input. If the response is not affirmative, $r m$ shall do nothing more with the current file and go on to any remaining files.
c. For each entry contained in file, other than dot or dot-dot, the four steps listed here ( 1 to 4 ) shall be taken with the entry as if it were a file operand. The rm utility shall not traverse directories by following symbolic links into other parts of the hierarchy, but shall remove the links themselves.
d. If the -i option is specified, $r m$ shall write a prompt to standard error and read a line from the standard input. If the response is not affirmative, $r m$ shall do nothing more with the current file, and go on to any remaining files.
3. If file is not of type directory, the -f option is not specified, and either the permissions of file do not permit writing and the standard input is a terminal or the -i option is specified, $r m$ shall write a prompt to the standard error and read a line from the standard input. If the response is not affirmative, $r m$ shall do nothing more with the current file and go on to any remaining files.
4. If the current file is a directory, $r m$ shall perform actions equivalent to the $r m d i r()$ function defined in the System Interfaces volume of IEEE Std 1003.1-200x called with a pathname of the current file used as the path argument. If the current file is not a directory, rm shall perform actions equivalent to the unlink() function defined in the System Interfaces volume of IEEE Std 1003.1-200x called with a pathname of the current file used as the path argument.

If this fails for any reason, $r m$ shall write a diagnostic message to standard error, do nothing more with the current file, and go on to any remaining files.
The rm utility shall be able to descend to arbitrary depths in a file hierarchy, and shall not fail
due to path length limitations (unless an operand specified by the user exceeds system limitations).

## OPTIONS

The rm utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

| $-\mathbf{f}$ | Do not prompt for confirmation. Do not write diagnostic messages or modify the <br> exit status in the case of nonexistent operands. Any previous occurrences of the -i <br> option shall be ignored. |
| :--- | :--- |
| $-\mathbf{i}$ | Prompt for confirmation as described previously. Any previous occurrences of the <br> $-\mathbf{f}$ option shall be ignored. |
| $-\mathbf{R}$ | Remove file hierarchies. See the DESCRIPTION. |
| $-\mathbf{r}$ | Equivalent to $-\mathbf{R}$. |

## OPERANDS

The following operand shall be supported:
file A pathname of a directory entry to be removed.

## STDIN

The standard input shall be used to read an input line in response to each prompt specified in the STDOUT section. Otherwise, the standard input shall not be used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of rm :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes within regular expressions used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.

LC_MESSAGES
Determine the locale for the processing of affirmative responses that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

Prompts shall be written to standard error under the conditions specified in the DESCRIPTION and OPTIONS sections. The prompts shall contain the file pathname, but their format is otherwise unspecified. The standard error also shall be used for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Each directory entry was successfully removed, unless its removal was canceled by a nonaffirmative response to a prompt for confirmation.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The $r m$ utility is forbidden to remove the names dot and dot-dot in order to avoid the consequences of inadvertently doing something like:
rm -r .*
Some implementations do not permit the removal of the last link to an executable binary file that is being executed; see the [EBUSY] error in the $\operatorname{mnlink}()$ function defined in the System Interfaces volume of IEEE Std 1003.1-200x. Thus, the $\begin{aligned} \\ m\end{aligned}$ utility can fail to remove such files.

The -i option causes $r m$ to prompt and read the standard input even if the standard input is not a terminal, but in the absence of $-\mathbf{i}$ the mode prompting is not done when the standard input is not a terminal.

## EXAMPLES

1. The following command:
```
rm a.out core
```

removes the directory entries: a.out and core.
2. The following command:

```
rm -Rf junk
```

removes the directory junk and all its contents, without prompting.

## RATIONALE

For absolute clarity, paragraphs (2b) and (3) in the DESCRIPTION of $r m$ describing the behavior when prompting for confirmation, should be interpreted in the following manner:

```
if ((NOT f_option) AND
    ((not_writable AND input_is_terminal) OR i_option))
```

The exact format of the interactive prompts is unspecified. Only the general nature of the contents of prompts are specified because implementations may desire more descriptive
prompts than those used on historical implementations. Therefore, an application not using the -f option, or using the -i option, relies on the system to provide the most suitable dialog directly with the user, based on the behavior specified.
The $-\mathbf{r}$ option is historical practice on all known systems. The synonym $-\mathbf{R}$ option is provided for consistency with the other utilities in this volume of IEEE Std 1003.1-200x that provide options requesting recursive descent through the file hierarchy.

The behavior of the -f option in historical versions of $r m$ is inconsistent. In general, along with "forcing" the unlink without prompting for permission, it always causes diagnostic messages to be suppressed and the exit status to be unmodified for nonexistent operands and files that cannot be unlinked. In some versions, however, the -f option suppresses usage messages and system errors as well. Suppressing such messages is not a service to either shell scripts or users.
It is less clear that error messages regarding files that cannot be unlinked (removed) should be suppressed. Although this is historical practice, this volume of IEEE Std 1003.1-200x does not permit the $-\mathbf{f}$ option to suppress such messages.
When given the -r and -i options, historical versions of rm prompt the user twice for each directory, once before removing its contents and once before actually attempting to delete the directory entry that names it. This allows the user to "prune" the file hierarchy walk. Historical versions of $r m$ were inconsistent in that some did not do the former prompt for directories named on the command line and others had obscure prompting behavior when the -i option was specified and the permissions of the file did not permit writing. The POSIX Shell and Utilities $r m$ differs little from historic practice, but does require that prompts be consistent. Historical versions of $r m$ were also inconsistent in that prompts were done to both standard output and standard error. This volume of IEEE Std 1003.1-200x requires that prompts be done to standard error, for consistency with $c p$ and $m v$, and to allow historical extensions to $r m$ that provide an option to list deleted files on standard output,
The rm utility is required to descend to arbitrary depths so that any file hierarchy may be deleted. This means, for example, that the rm utility cannot run out of file descriptors during its descent (that is, if the number of file descriptors is limited, $r m$ cannot be implemented in the historical fashion where one file descriptor is used per directory level). Also, rm is not permitted to fail because of path length restrictions, unless an operand specified by the user is longer than \{PATH_MAX\}.

The rm utility removes symbolic links themselves, not the files they refer to, as a consequence of the dependence on the unlink() functionality, per the DESCRIPTION. When removing hierarchies with $-\mathbf{r}$ or $-\mathbf{R}$, the prohibition on following symbolic links has to be made explicit.

## FUTURE DIRECTIONS

## NAME

rmdel - remove a delta from an SCCS file (DEVELOPMENT)

## SYNOPSIS

XSI rmdel -r SID file...

## DESCRIPTION

The rmdel utility shall remove the delta specified by the SID from each named SCCS file. The delta to be removed shall be the most recent delta in its branch in the delta chain of each named SCCS file. In addition, the application shall ensure that the SID specified is not that of a version being edited for the purpose of making a delta; that is, if a $p$-file (see get) exists for the named SCCS file, the SID specified shall not appear in any entry of the $p$-file.
Removal of a delta shall be restricted to:

1. The user who made the delta
2. The owner of the SCCS file
3. The owner of the directory containing the SCCS file

## OPTIONS

The rmdel utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-r SID Specify the SCCS identification string (SID) of the delta to be deleted.

## OPERANDS

The following operand shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the rmdel utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with s.) and unreadable files shall be silently ignored.

If exactly one file operand appears, and it is ' ${ }^{\prime}$, the standard input shall be read; each line of the standard input is taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

## STDIN

The standard input shall be a text file used only when the file operand is specified as ${ }^{\prime} \quad{ }^{\prime}$. Each line of the text file shall be interpreted as an SCCS pathname.

## INPUT FILES

The SCCS files shall be files of unspecified format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of rmdel:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L \quad$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.
STDOUT
Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The SCCS files shall be files of unspecified format. During processing of a file, a temporary $x$-file, as described in admin, may be created and deleted; a locking $z$-file, as described in get, may be created and deleted.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.

NAME
rmdir - remove directories
SYNOPSIS
rmdir [-p] dir...
DESCRIPTION
The rmdir utility shall remove the directory entry specified by each dir operand.
For each dir operand, the rmdir utility shall perform actions equivalent to the $r$ rmdir() function called with the dir operand as its only argument.
Directories shall be processed in the order specified. If a directory and a subdirectory of that directory are specified in a single invocation of the rmdir utility, the application shall specify the subdirectory before the parent directory so that the parent directory will be empty when the rmdir utility tries to remove it.
OPTIONS
The rmdir utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-p Remove all directories in a pathname. For each dir operand:

1. The directory entry it names shall be removed.
2. If the dir operand includes more than one pathname component, effects equivalent to the following command shall occur:
rmdir -p \$(dirname dir)

## OPERANDS

The following operand shall be supported:

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of rmdir:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Each directory entry specified by a dir operand was removed successfully.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The definition of an empty directory is one that contains, at most, directory entries for dot and dot-dot.

## EXAMPLES

If a directory $\mathbf{a}$ in the current directory is empty except it contains a directory $\mathbf{b}$ and $\mathbf{a} / \mathbf{b}$ is empty except it contains a directory $\mathbf{c}$ :
rmdir -p a/b/c
removes all three directories.

## RATIONALE

On historical System V systems, the -p option also caused a message to be written to the standard output. The message indicated whether the whole path was removed or whether part of the path remained for some reason. The STDERR section requires this diagnostic when the entire path specified by a dir operand is not removed, but does not allow the status message reporting success to be written as a diagnostic.
The rmdir utility on System V also included a -s option that suppressed the informational message output by the $-\mathbf{p}$ option. This option has been omitted because the informational message is not specified by this volume of IEEE Std 1003.1-200x.

## FUTURE DIRECTIONS

None.

## SEE ALSO

$r m$, the System Interfaces volume of IEEE Std 1003.1-200x, remove( ), rmdir(), unlink()

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.

## NAME

sact - print current SCCS file-editing activity (DEVELOPMENT)

## SYNOPSIS

```
xSI sact file...
```

## DESCRIPTION

The sact utility shall inform the user of any impending deltas to a named SCCS file by writing a list to standard output. This situation occurs when get - $\mathbf{e}$ has been executed previously without a subsequent execution of delta, unget, or sccs unedit.

## OPTIONS

None.

## OPERANDS

The following operand shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the sact utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with s.) and unreadable files shall be silently ignored.

If exactly one file operand appears, and it is ${ }^{\prime}-^{\prime}$, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

## STDIN

The standard input shall be a text file used only when the file operand is specified as ' -' . Each line of the text file shall be interpreted as an SCCS pathname.

## INPUT FILES

Any SCCS files interrogated are files of an unspecified format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of sact:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of $L C$ _MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The output for each named file shall consist of a line in the following format:
"\% $\mathrm{S} \Delta \% \mathrm{~S} \Delta \% \mathrm{~S} \Delta \% \mathrm{~s} \Delta \% \mathrm{~S} \backslash \mathrm{n} ",<S I D>,<n e w ~ S I D>,<l o g i n>,<d a t e>,<t i m e>$
<SID> Specifies the SID of a delta that currently exists in the SCCS file to which changes are made to make the new delta.
<new SID> Specifies the SID for the new delta to be created.
<login> Contains the login name of the user who makes the delta (that is, who executed a get for editing).
<date> $\quad$ Contains the date that get -e was executed, in the format used by the prs :D: data keyword.
<time> Contains the time that get -e was executed, in the format used by the prs :T: data keyword.

If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:
"\n\%s:\n", <pathname>

## STDERR

The standard error shall be used only for optional informative messages concerning SCCS files with no impending deltas, and for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

None.

## EXAMPLES

First released in Issue 2.

NAME
sccs - front end for the SCCS subsystem (DEVELOPMENT)

## SYNOPSIS

xSI sccs [-r] [-d path] [-p path] command [options...] [operands...]

## DESCRIPTION

The sccs utility is a front end to the SCCS programs. It also includes the capability to run set-user-id to another user to provide additional protection.
The sccs utility shall invoke the specified command with the specified options and operands. By default, each of the operands shall be modified by prefixing it with the string "SCCS/s.".
The command can be the name of one of the SCCS utilities in this volume of IEEE Std 1003.1-200x (admin, delta, get, prs, rmdel, sact, unget, val, or what) or one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.

## OPTIONS

The sccs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that options operands are actually options to be passed to the utility named by command. When the portion of the command:

```
command [options ... ] [operands ... ]
```

is considered, all of the pseudo-utilities used as command shall support the Utility Syntax Guidelines. Any of the other SCCS utilities that can be invoked in this manner support the Guidelines to the extent indicated by their individual OPTIONS sections.
The following options shall be supported preceding the command operand:

> -d path A pathname of a directory to be used as a root directory for the SCCS files. The default shall be the current directory. The -d option shall take precedence over the PROJECTDIR variable. See -p.
> - $\mathbf{p}$ path A pathname of a directory in which the SCCS files are located. The default shall be the SCCS directory.
> The -p option differs from the $-\mathbf{d}$ option in that the $-\mathbf{d}$ option-argument shall be prefixed to the entire pathname and the -p option-argument shall be inserted before the final component of the pathname. For example:
> converts to:
> This allows the creation of aliases such as:
> which is used as:
> -r Invoke command with the real user ID of the process, not any effective user ID that the sccs utility is set to. Certain commands (admin, check, clean, diffs, info, rmdel, and tell) cannot be run set-user-ID by all users, since this would allow anyone to change the authorizations. These commands are always run as the real user.

OPERANDS
The following operands shall be supported:
command An SCCS utility name or the name of one of the pseudo-utilities listed in the EXTENDED DESCRIPTION section.
options An option or option-argument to be passed to command.
operands An operand to be passed to command.

## STDIN

See the utility description for the specified command.

## INPUT FILES

See the utility description for the specified command.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of sccs:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PROJECTDIR
Provide a default value for the - $\mathbf{d}$ path option. If the value of PROJECTDIR begins with a slash, it shall be considered an absolute pathname; otherwise, the value of PROJECTDIR is treated as a user name and that user's initial working directory shall be examined for a subdirectory src or source. If such a directory is found, it shall be used. Otherwise, the value shall be used as a relative pathname.
Additional environment variable effects may be found in the utility description for the specified command.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

See the utility description for the specified command.

## STDERR

See the utility description for the specified command.

## OUTPUT FILES

See the utility description for the specified command.

## EXTENDED DESCRIPTION

The following pseudo-utilities shall be supported as command operands. All options referred to in the following list are values given in the options operands following command.
check Equivalent to info, except that nothing shall be printed if nothing is being edited, and a non-zero exit status shall be returned if anything is being edited. The intent is to have this included in an "install" entry in a makefile to ensure that everything is included into the SCCS file before a version is installed.
clean Remove everything from the current directory that can be recreated from SCCS files, but do not remove any files being edited. If the -b option is given, branches shall be ignored in the determination of whether they are being edited; this is dangerous if branches are kept in the same directory.
create Create an SCCS file, taking the initial contents from the file of the same name. Any options to admin are accepted. If the creation is successful, the original files shall be renamed by prefixing the basenames with a comma. These renamed files should be removed after it has been verified that the SCCS files have been created successfully.
delget Perform a delta on the named files and then get new versions. The new versions shall have ID keywords expanded and shall not be editable. Any $-\mathbf{m},-\mathbf{p},-\mathbf{r},-\mathbf{s}$, and $-\mathbf{y}$ options shall be passed to delta, and any $-\mathbf{b},-\mathbf{c},-\mathbf{e},-\mathbf{i},-\mathbf{k},-\mathbf{l},-\mathbf{s}$, and $-\mathbf{x}$ options shall be passed to get.
deledit Equivalent to delget, except that the get phase shall include the -e option. This option is useful for making a checkpoint of the current editing phase. The same options shall be passed to delta as described above, and all the options listed for get above except -e shall be passed to edit.
diffs Write a difference listing between the current version of the files checked out for editing and the versions in SCCS format. Any $-\mathbf{r},-\mathbf{c},-\mathbf{i},-\mathbf{x}$, and $-\mathbf{t}$ options shall be passed to get; any $-\mathbf{l},-\mathbf{s},-\mathbf{e},-\mathbf{f},-\mathbf{h}$, and $-\mathbf{b}$ options shall be passed to diff. A $-\mathbf{C}$ option shall be passed to diff as -c.
edit Equivalent to get -e.
fix Remove the named delta, but leave a copy of the delta with the changes that were in it. It is useful for fixing small compiler bugs, and so on. The application shall ensure that it is followed by a $-\mathbf{r}$ SID option. Since fix does not leave audit trails, it should be used carefully.
info Write a listing of all files being edited. If the $-\mathbf{b}$ option is given, branches (that is, SIDs with two or fewer components) shall be ignored. If a -u user option is given, then only files being edited by the named user shall be listed. A $-\mathbf{U}$ option shall be equivalent to -u<current user $>$.
print Write out verbose information about the named files, equivalent to sccs prs.
tell Write a <newline>-separated list of the files being edited to standard output. Takes the $-\mathbf{b},-\mathbf{u}$, and $-\mathbf{U}$ options like info and check.
unedit This is the opposite of an edit or a get -e. It should be used with caution, since any changes made since the get are lost.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Many of the SCCS utilities take directory names as operands as well as specific filenames. The pseudo-utilities supported by sccs are not described as having this capability, but are not prohibited from doing so.

## EXAMPLES

1. To get a file for editing, edit it and produce a new delta:
```
sccs get -e file.c
ex file.c
sccs delta file.c
```

2. To get a file from another directory:
```
sccs -p /usr/src/sccs/s. get cc.c
```

or:
sccs get /usr/src/sccs/s.cc.c
3. To make a delta of a large number of files in the current directory:

```
sccs delta *.c
```

4. To get a list of files being edited that are not on branches:
```
sccs info -b
```

5. To delta everything being edited by the current user:
```
sccs delta $(sccs tell -U)
```

6. In a makefile, to get source files from an SCCS file if it does not already exist:
```
SRCS = <list of source files>
$ (SRCS):
    sccs get $(REL) $@
```

## RATIONALE

sccs and its associated utilities are part of the XSI Development Utilities option within the XSI option.
SCCS is an abbreviation for Source Code Control System. It is a maintenance and enhancement tracking tool. When a file is put under SCCS, the source code control system maintains the file and, when changes are made, identifies and stores them in the file with the original source code and/or documentation. As other changes are made, they too are identified and retained in the file.

Retrieval of the original and any set of changes is possible. Any version of the file as it develops can be reconstructed for inspection or additional modification. History data can be stored with each version, documenting why the changes were made, who made them, and when they were made.

## CHANGE HISTORY

First released in Issue 4.

Issue 6
In the ENVIRONMENT VARIABLES section, the PROJECTDIR description is updated from "otherwise, the home directory of a user of that name is examined" to "otherwise, the value of PROJECTDIR is treated as a user name and that user's initial working directory is examined".

The normative text is reworded to avoid use of the term "must" for application requirements.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME

> sed - stream editor

## SYNOPSIS

```
sed [-n] script [file...]
sed -e script [-e script]... [-f script_file]... [-n] [file...]
sed [-e script]... -f script_file [-f script_file]... [-n] [file...]
```

## DESCRIPTION

The sed utility is a stream editor that shall read one or more text files, make editing changes according to a script of editing commands, and write the results to standard output. The script shall be obtained from either the script operand string or a combination of the option-arguments from the -e script and -f script_file options.

## OPTIONS

The sed utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the order of presentation of the -e and -f options is significant.
The following options shall be supported:
-e script Add the editing commands specified by the script option-argument to the end of the script of editing commands. The script option-argument shall have the same properties as the script operand, described in the OPERANDS section.
-f script_file Add the editing commands in the file script_file to the end of the script.
-n Suppress the default output (in which each line, after it is examined for editing, is written to standard output). Only lines explicitly selected for output are written.

Multiple -e and -f options may be specified. All commands shall be added to the script in the order specified, regardless of their origin.

## OPERANDS

The following operands shall be supported:
file A pathname of a file whose contents are read and edited. If multiple file operands are specified, the named files shall be read in the order specified and the concatenation shall be edited. If no file operands are specified, the standard input shall be used.
script A string to be used as the script of editing commands. The application shall not present a script that violates the restrictions of a text file except that the final character need not be a <newline>.

## STDIN

The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

The input files shall be text files. The script_files named by the -f option shall consist of editing commands.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of sed:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within regular expressions.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), and the behavior of character classes within regular expressions.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The input files shall be written to standard output, with the editing commands specified in the script applied. If the $-\mathbf{n}$ option is specified, only those input lines selected by the script shall be written to standard output.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The output files shall be text files whose formats are dependent on the editing commands given.

## EXTENDED DESCRIPTION

The script shall consist of editing commands of the following form:
[address[,address]]function
where function represents a single-character command verb from the list in Editing Commands in sed (on page 845), followed by any applicable arguments.
The command can be preceded by <blank>s and/or semicolons. The function can be preceded by <blank>s. These optional characters shall have no effect.
In default operation, sed cyclically shall append a line of input, less its terminating <newline>, into the pattern space. Normally the pattern space will be empty, unless a $\mathbf{D}$ command terminated the last cycle. The sed utility shall then apply in sequence all commands whose addresses select that pattern space, and at the end of the script copy the pattern space to standard output (except when $-\mathbf{n}$ is specified) and delete the pattern space. Whenever the pattern space is written to standard output or a named file, sed shall immediately follow it with a <newline>.

Some of the editing commands use a hold space to save all or part of the pattern space for subsequent retrieval. The pattern and hold spaces shall each be able to hold at least 8192 bytes.

## Addresses in sed

An address is either a decimal number that counts input lines cumulatively across files, a '\$' character that addresses the last line of input, or a context address (which consists of a BRE, as described in Regular Expressions in sed (on page 845), preceded and followed by a delimiter, usually a slash).

An editing command with no addresses shall select every pattern space.
An editing command with one address shall select each pattern space that matches the address.
An editing command with two addresses shall select the inclusive range from the first pattern space that matches the first address through the next pattern space that matches the second. (If the second address is a number less than or equal to the line number first selected, only one line shall be selected.) Starting at the first line following the selected range, sed shall look again for the first address. Thereafter, the process shall be repeated. Omitting either or both of the address components in the following form produces undefined results:
[address[, address]]

## Regular Expressions in sed

The sed utility shall support the BREs described in the Base Definitions volume of IEEE Std 1003.1-200x, Section 9.3, Basic Regular Expressions, with the following additions:

- In a context address, the construction " $\backslash$ cBREc", where $c$ is any character other than backslash or <newline>, shall be identical to "/BRE/". If the character designated by c appears following a backslash, then it shall be considered to be that literal character, which shall not terminate the BRE. For example, in the context address " $\backslash x a b c \backslash x d e f x$ ", the second $x$ stands for itself, so that the BRE is "abcxdef".
- The escape sequence ' $\backslash n$ ' shall match a <newline> embedded in the pattern space. A literal <newline> shall not be used in the BRE of a context address or in the substitute function.
- If an RE is empty (that is, no pattern is specified) sed shall behave as if the last RE used in the last command applied (either as an address or as part of a substitute command) was specified.

## Editing Commands in sed

In the following list of editing commands, the maximum number of permissible addresses for each function is indicated by [0addr], [1addr], or [2addr], representing zero, one, or two addresses.

The argument text shall consist of one or more lines. Each embedded <newline> in the text shall be preceded by a backslash. Other backslashes in text shall be removed, and the following character shall be treated literally.

The $\mathbf{r}$ and $\mathbf{w}$ command verbs, and the $w$ flag to the $\mathbf{s}$ command, take an rfile (or wfile) parameter, separated from the command verb letter or flag by one or more <blank>s; implementations may allow zero separation as an extension.
The argument $r$ file or the argument wfile shall terminate the editing command. Each wfile shall be created before processing begins. Implementations shall support at least ten wfile arguments in the script; the actual number (greater than or equal to 10) that is supported by the implementation is unspecified. The use of the wfile parameter shall cause that file to be initially created, if it does not exist, or shall replace the contents of an existing file.
The $\mathbf{b}, \mathbf{r}, \mathbf{s}, \mathbf{t}, \mathbf{w}, \mathbf{y}$, and : command verbs shall accept additional arguments. The following synopses indicate which arguments shall be separated from the command verbs by a single
<space>.
The $\mathbf{a}$ and $\mathbf{r}$ commands schedule text for later output. The text specified for the a command, and the contents of the file specified for the $\mathbf{r}$ command, shall be written to standard output just before the next attempt to fetch a line of input when executing the $\mathbf{N}$ or $\mathbf{n}$ commands, or when reaching the end of the script. If written when reaching the end of the script, and the $-\mathbf{n}$ option was not specified, the text shall be written after copying the pattern space to standard output. The contents of the file specified for the $\mathbf{r}$ command shall be as of the time the output is written, not the time the $\mathbf{r}$ command is applied. The text shall be output in the order in which the a and $\mathbf{r}$ commands were applied to the input.
Command verbs other than $\{, \mathbf{a}, \mathbf{b}, \mathbf{c}, \mathbf{i}, \mathbf{r}, \mathbf{t}, \mathbf{w},:$, and \# can be followed by a semicolon, optional <blank>s, and another command verb. However, when the s command verb is used with the $w$ flag, following it with another command in this manner produces undefined results.
A function can be preceded by one or more ' !' characters, in which case the function shall be applied if the addresses do not select the pattern space. Zero or more <blank>s shall be accepted before the first ' !' character. It is unspecified whether <blank>s can follow a' !' character, and conforming applications shall not follow a' !' character with <blank>s.
[2addr] \{function
function
\} Execute a list of sed functions only when the pattern space is selected. The list of sed functions shall be surrounded by braces and separated by <newline>s, and conform to the following rules. The braces can be preceded or followed by <blank>s. The functions can be preceded by <blank>s, but shall not be followed by <blank>s. The <right-brace> shall be preceded by a <newline> and can be preceded or followed by <blank>s.

## [1addr]a\}

text
Write text to standard output as described previously.
[2addr]b [label]
Branch to the: function bearing the label. If label is not specified, branch to the end of the script. The implementation shall support labels recognized as unique up to at least 8 characters; the actual length (greater than or equal to 8) that shall be supported by the implementation is unspecified. It is unspecified whether exceeding a label length causes an error or a silent truncation.
[2addr]c $\backslash$
text
Delete the pattern space. With a 0 or 1 address or at the end of a 2 -address range, place text on the output and start the next cycle.
[2addr]d Delete the pattern space and start the next cycle.
[2addr]D Delete the initial segment of the pattern space through the first <newline> and start the next cycle.
[2addr]g Replace the contents of the pattern space by the contents of the hold space.
[2addr]G Append to the pattern space a <newline> followed by the contents of the hold space.
[2addr]h Replace the contents of the hold space with the contents of the pattern space.
[2addr]H Append to the hold space a <newline> followed by the contents of the pattern space.

| [1add text | Write text to standard output. |
| :---: | :---: |
| [2addr] 1 | (The letter ell.) Write the pattern space to standard output in a visually unambiguous form. The characters listed in the Base Definitions volume IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (' $\left.\prime \backslash a^{\prime}, ' \backslash b^{\prime}, ' \backslash f^{\prime}, ' \backslash r^{\prime}, ~ \backslash t^{\prime}, ~ ' \backslash v^{\prime}\right)$ shall be written as the corresponding escape sequence; the ' $\backslash n$ ' in that table is not applicable. Non-printable characters not in that table shall be written as one three-digit octal number (with a preceding backslash) for each byte in the character (most significant byte first). |
|  | Long lines shall be folded, with the point of folding indicated by writing a backslash followed by a <newline>; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line shall be marked with a ' $\$$ '. |
| [2addr]n | Write the pattern space to standard output if the default output has not been suppressed, and replace the pattern space with the next line of input, less its terminating <newline>. |
|  | If no next line of input is available, the $\mathbf{n}$ command verb shall branch to the end of the script and quit without starting a new cycle. |
| [2addr ] $\mathbf{N}$ | Append the next line of input, less its terminating <newline>, to the pattern space, using an embedded <newline> to separate the appended material from the original material. Note that the current line number changes. |
|  | If no next line of input is available, the $\mathbf{N}$ command verb shall branch to the end of the script and quit without starting a new cycle or copying the pattern space to standard output. |
| [2addr] | , |
| [2addr] $\mathbf{P}$ | Write the pattern space, up to the first <newline>, to standard output. |
|  | Br |
| [1addr $\rceil \mathbf{r} r$ file Copy the contents of $r$ file to standard output as described previously. If $r$ file does not exist or cannot be read, it shall be treated as if it were an empty file, causing no error condition. <br> [2addr]s/BRE/replacement/flags |  |
|  |  |
|  | Substitute the replacement string for instances of the BRE in the pattern space. Any character other than backslash or <newline> can be used instead of a slash to delimit the BRE and the replacement. Within the BRE and the replacement, the BRE delimiter itself can be used as a literal character if it is preceded by a backslash. |
|  | The replacement string shall be scanned from beginning to end. An ampersand ( ${ }^{\prime} \delta^{\prime}$ ) appearing in the replacement shall be replaced by the string matching the BRE. The special meaning of ' ${ }_{\delta}$ ' in this context can be suppressed by preceding it by a backslash. The characters " $\backslash n$ ", where $n$ is a digit, shall be replaced by the text matched by the corresponding back-reference expression. If the corresponding back-reference expression does not match, then the characters " $\backslash n$ " shall be replaced by the empty string. The special meaning of " $\backslash n$ " where $n$ is a digit in this context, can be suppressed by preceding it by a backslash. For each other backslash ( ${ }^{\prime} \backslash^{\prime}$ ) encountered, the following character shall lose its special meaning (if any). The meaning of a ' $\backslash$ ' immediately followed by any character other than ' $\delta^{\prime},{ }^{\prime} \backslash$ ', a digit, or the delimiter character used for this command, is unspecified |

A line can be split by substituting a <newline> into it. The application shall escape
the <newline> in the replacement by preceding it by a backslash. A substitution shall be considered to have been performed even if the replacement string is identical to the string that it replaces. Any backslash used to alter the default meaning of a subsequent character shall be discarded from the BRE or the replacement before evaluating the BRE or using the replacement.

The value of flags shall be zero or more of:
$n \quad$ Substitute for the $n$th occurrence only of the BRE found within the pattern space.
g Globally substitute for all non-overlapping instances of the BRE rather than just the first one. If both $\mathbf{g}$ and $n$ are specified, the results are unspecified.
p Write the pattern space to standard output if a replacement was made.
$\mathbf{w}$ wfile $\quad$ Write. Append the pattern space to $w$ file if a replacement was made. A conforming application shall precede the wfile argument with one or more <blank>s. If the $\mathbf{w}$ flag is not the last flag value given in a concatenation of multiple flag values, the results are undefined.
[2addr]t [label]
Test. Branch to the : command verb bearing the label if any substitutions have been made since the most recent reading of an input line or execution of a $\mathbf{t}$. If label is not specified, branch to the end of the script.
[2addr]w wfile
Append (write) the pattern space to wfile.
[2addr] $\mathbf{x}$ Exchange the contents of the pattern and hold spaces.
[2addr]y/string1/string2/
Replace all occurrences of characters in string1 with the corresponding characters in string2. If a backslash followed by an ' n ' appear in string1 or string2, the two characters shall be handled as a single <newline>. If the number of characters in string1 and string2 are not equal, or if any of the characters in string1 appear more than once, the results are undefined. Any character other than backslash or <newline> can be used instead of slash to delimit the strings. If the delimiter is not ' n ', within string1 and string2, the delimiter itself can be used as a literal character if it is preceded by a backslash. If a backslash character is immediately followed by a backslash character in string1 or string2, the two backslash characters shall be counted as a single literal backslash character. The meaning of a backslash followed by any character that is not ' n ', a backslash, or the delimiter character is undefined.
[Oaddr]:label Do nothing. Thís command bears a label to which the $\mathbf{b}$ and $\mathbf{t}$ commands branch.
[1addr] $=\quad$ Write the following to standard output:
"\%d\n", <current line number>
[Oaddr] Ignore this empty command.
[Oaddr] Ignore the ' \#' and the remainder of the line (treat them as a comment), with the single exception that if the first two characters in the script are " $\# \mathrm{n}$ ", the default output shall be suppressed; this shall be the equivalent of specifying -n on the command line.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Regular expressions match entire strings, not just individual lines, but a <newline> is matched by ' $\backslash \mathrm{n}$ ' in a sed RE; a <newline> is not allowed by the general definition of regular expression in IEEE Std 1003.1-200x. Also note that ' $\backslash n$ ' cannot be used to match a <newline> at the end of an arbitrary input line; <newline>s appear in the pattern space as a result of the $\mathbf{N}$ editing command.

## EXAMPLES

This sed script simulates the BSD cat -s command, squeezing excess blank lines from standard input.

$$
\text { sed }-n \text { ' }
$$

\# Write non-empty lines.
/./ \{
p
d
\}
\# Write a single empty line, then look for more empty lines.
/^\$/ p
\# Get next line, discard the held <newline> (empty line),
\# and look for more empty lines.
: Empty
/^\$/
N
s/.N
b Empty
\}
\# Write the non-empty line before going back to search
\# for the first in a set of empty lines.
p

## RATIONALE

This volume of IEEE Std 1003.1-200x requires implementations to support at least ten distinct wfiles, matching historical practice on many implementations. Implementations are encouraged to support more, but conforming applications should not exceed this limit.

The exit status codes specified here are different from those in System V. System V returns 2 for garbled sed commands, but returns zero with its usage message or if the input file could not be opened. The standard developers considered this to be a bug.

The manner in which the $\mathbf{1}$ command writes non-printable characters was changed to avoid the historical backspace-overstrike method, and other requirements to achieve unambiguous output were added. See the RATIONALE for $e d$ for details of the format chosen, which is the same as that chosen for sed.

This volume of IEEE Std 1003.1-200x requires implementations to provide pattern and hold spaces of at least 8192 bytes, larger than the 4000 bytes spaces used by some historical implementations, but less than the 20480 bytes limit used in an early proposal. Implementations
are encouraged to allocate dynamically larger pattern and hold spaces as needed.
The requirements for acceptance of <blank>s and <space>s in command lines has been made more explicit than in early proposals to describe clearly the historical practice and to remove confusion about the phrase "protect initial blanks [sic] and tabs from the stripping that is done on every script line" that appears in much of the historical documentation of the sed utility description of text. (Not all implementations are known to have stripped <blank>s from text lines, although they all have allowed leading <blank>s preceding the address on a command line.)

The treatment of ' \#' comments differs from the SVID which only allows a comment as the first line of the script, but matches BSD-derived implementations. The comment character is treated as a command, and it has the same properties in terms of being accepted with leading <blank>s; the BSD implementation has historically supported this.
Early proposals required that a script file have at least one non-comment line. Some historical implementations have behaved in unexpected ways if this were not the case. The standard developers considered that this was incorrect behavior and that application developers should not have to avoid this feature. A correct implementation of this volume of IEEE Std 1003.1-200x shall permit script_files that consist only of comment lines.

Early proposals indicated that if -e and -f options were intermixed, all -e options were processed before any -f options. This has been changed to process them in the order presented because it matches historical practice and is more intuitive.

The treatment of the $\mathbf{p}$ flag to the $\mathbf{s}$ command differs between System V and BSD-based systems when the default output is suppressed. In the two examples:

| echo a | sed 's/a/A/p' |
| :--- | :--- | :--- |

echo a $\mid$ sed $-n^{\prime} s / a / A / p^{\prime}$
this volume of IEEE Std 1003.1-200x, BSD, System V documentation, and the SVID indicate that the first example should write two lines with $\mathbf{A}$, whereas the second should write one. Some System V systems write the $\mathbf{A}$ only once in both examples because the $\mathbf{p}$ flag is ignored if the $-\mathbf{n}$ option is not specified.

This is a case of a diametrical difference between systems that could not be reconciled through the compromise of declaring the behavior to be unspecified. The SVID/BSD/System V documentation behavior was adopted for this volume of IEEE Std 1003.1-200x because:

- No known documentation for any historic system describes the interaction between the $\mathbf{p}$ flag and the -n option.
- The selected behavior is more correct as there is no technical justification for any interaction between the $\mathbf{p}$ flag and the $-\mathbf{n}$ option. A relationship between $-\mathbf{n}$ and the $\mathbf{p}$ flag might imply that they are only used together, but this ignores valid scripts that interrupt the cyclical nature of the processing through the use of the $\mathbf{D}, \mathbf{d}, \mathbf{q}$, or branching commands. Such scripts rely on the $\mathbf{p}$ suffix to write the pattern space because they do not make use of the default output at the "bottom" of the script.
- Because the $-\mathbf{n}$ option makes the $\mathbf{p}$ flag unnecessary, any interaction would only be useful if sed scripts were written to run both with and without the $-n$ option. This is believed to be unlikely. It is even more unlikely that programmers have coded the $\mathbf{p}$ flag expecting it to be unnecessary. Because the interaction was not documented, the likelihood of a programmer discovering the interaction and depending on it is further decreased.
- Finally, scripts that break under the specified behavior produce too much output instead of too little, which is easier to diagnose and correct.
The form of the substitute command that uses the $\mathbf{n}$ suffix was limited to the first 512 matches in an early proposal. This limit has been removed because there is no reason an editor processing
lines of $\{$ LINE_MAX $\}$ length should have this restriction. The command s/a/A/2047 should be able to substitute the 2047 th occurrence of a on a line.

The $\mathbf{b}, \mathbf{t}$, and : commands are documented to ignore leading white space, but no mention is made of trailing white space. Historical implementations of sed assigned different locations to the labels ' x ' and " x ". This is not useful, and leads to subtle programming errors, but it is historical practice, and changing it could theoretically break working scripts. Implementors are encouraged to provide warning messages about labels that are never used or jumps to labels that do not exist.

Historically, the sed ! and \} editing commands did not permit multiple commands on a single line using a semicolon as a command delimiter. Implementations are permitted, but not required, to support this extension.
Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

## FUTURE DIRECTIONS

None.

awk, ed, grep

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.

## Issue 6

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- Implementations are required to support at least ten wfile arguments in an editing command.

The EXTENDED DESCRIPTION is changed to align with the IEEE P1003.2b draft standard.
IEEE PASC Interpretation 1003.2 \#190 is applied.
IEEE PASC Interpretation 1003.2 \#203 is applied, clarifying the meaning of the backslash escape sequences in a replacement string for a BRE.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/28 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/29 is applied, making an editorial correction within the Editing Commands in sed section.
Issue 7
Austin Group Interpretations 1003.1-2001 \#006 and \#036 are applied.
SD5-XCU-ERN-97 and SD5-XCU-ERN-123 are applied, updating the SYNOPSIS.

## NAME

sh — shell, the standard command language interpreter

## SYNOPSIS

```
sh [-abCefhimnuvx] [-o option]... [+abCefhimnuvx] [+o option]...
        [command_file [argument...]]
    sh -c [-abCefhimnuvx] [-o option]... [+abCefhimnuvx] [+o option]...
        command_string [command_name [argument...]]
    sh -s [-abCefhimnuvx] [-o option]... [+abCefhimnuvx] [+o option]...
    [argument...]
```

## DESCRIPTION

The sh utility is a command language interpreter that shall execute commands read from a command line string, the standard input, or a specified file. The application shall ensure that the commands to be executed are expressed in the language described in Chapter 2 (on page 29).

Pathname expansion shall not fail due to the size of a file.
Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

## OPTIONS

The sh utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, with an extension for support of a leading plus sign ( ${ }^{\prime}+{ }^{\prime}$ ) as noted below.

The $-\mathbf{a},-\mathbf{b},-\mathbf{C},-\mathbf{e},-\mathbf{f},-\mathbf{m},-\mathbf{n},-\mathbf{o}$ option, $-\mathbf{u},-\mathbf{v}$, and $-\mathbf{x}$ options are described as part of the set utility in Section 2.14 (on page 64). The option letters derived from the set special built-in shall also be accepted with a leading plus sigh ( $\prime^{\prime}$ ) instead of a leading hyphen (meaning the reverse case of the option as described in this volume of IEEE Std 1003.1-200x).

The following additional options shall be supported:
-c Read commands from the command_string operand. Set the value of special
parameter 0 (see Section 2.5 .2 (on page 34)) from the value of the command_name
operand and the positional parameters ( $\$ 1, \$ 2$, and so on) in sequence from the
remaining argument operands. No commands shall be read from the standard
input.
Specify that the shell is interactive; see below. An implementation may treat
specifying the -i option as an error if the real user ID of the calling process does
not equal the effective user ID or if the real group ID does not equal the effective
group ID.
-i

If there are no operands and the -c option is not specified, the $-\mathbf{s}$ option shall be assumed.
If the $-\mathbf{i}$ option is present, or if there are no operands and the shell's standard input and standard error are attached to a terminal, the shell is considered to be interactive.

## OPERANDS

The following operands shall be supported:

- A single hyphen shall be treated as the first operand and then ignored. If both ' -' and "--" are given as arguments, or if other operands precede the single hyphen, the results are undefined.
argument The positional parameters ( $\$ 1, \$ 2$, and so on) shall be set to arguments, if any.
command_file The pathname of a file containing commands. If the pathname contains one or more slash characters, the implementation attempts to read that file; the file need not be executable. If the pathname does not contain a slash character:
- The implementation shall attempt to read that file from the current working directory; the file need not be executable.
- If the file is not in the current working directory, the implementation may perform a search for an executable file using the value of PATH, as described in Section 2.9.1.1 (on page 48).

Special parameter 0 (see Section 2.5.2 (on page 34)) shall be set to the value of command_file. If sh is called using a synopsis form that omits command_file, special parameter 0 shall be set to the value of the first argument passed to sh from its parent (for example, $\operatorname{argv}[0]$ for a C program), which is normally a pathname used to execute the sh utility.

## command_name

A string assigned to special parameter 0 when executing the commands in command_string. If command_name is not specified, special parameter 0 shall be set to the value of the first argument passed to sh from its parent (for example, argv[0] for a C program), which is normally a pathname used to execute the sh utility.
command_string
A string that shall be interpreted by the shell as one or more commands, as if the string were the argument to the system() function defined in the System Interfaces volume of IEEE Std 1003.1-200x. If the command_string operand is an empty string, sh shall exit with a zero exit status.

## STDIN

The standard input shall be used only if one of the following is true:

- The -s option is specified.
- The -c option is not specified and no operands are specified.
- The script executes one or more commands that require input from standard input (such as a read command that does not redirect its input).

See the INPUT FILES section.
When the shell is using standard input and it invokes a command that also uses standard input, the shell shall ensure that the standard input file pointer points directly after the command it has read when the command begins execution. It shall not read ahead in such a manner that any characters intended to be read by the invoked command are consumed by the shell (whether interpreted by the shell or not) or that characters that are not read by the invoked command are not seen by the shell. When the command expecting to read standard input is started asynchronously by an interactive shell, it is unspecified whether characters are read by the command or interpreted by the shell.
If the standard input to $s h$ is a FIFO or terminal device and is set to non-blocking reads, then $s h$ shall enable blocking reads on standard input. This shall remain in effect when the command completes.

## INPUT FILES

The input file shall be a text file, except that line lengths shall be unlimited. If the input file is empty or consists solely of blank lines or comments, or both, sh shall exit with a zero exit status.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of sh:
ENV This variable, when and only when an interactive shell is invoked, shall be subjected to parameter expansion (see Section 2.6.2 (on page 38)) by the shell, and the r

$L C \_A L L$ If set to a non-empty string value, override the values of all the other LC_COLLATE

Determine the behavior of range expressions, equivalence classes, and multicharacter collating elements within pattern matching.
characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), which characters are defined as letters (character class alpha), and the behavior of character classes within pattern matching.

Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error. notification. If this variable is set, the shell shall inform the user if the file named by the variable is created or if its modification time has changed. Informing the user shall be accomplished by writing a string of unspecified format to standard error prior to the writing of the next primary prompt string. Such check shall be performed only after the completion of the interval defined by the MAILCHECK variable after the last such check. The user shall be informed only if MAIL is set and MAILPATH is not set.
up MAILCHECK
Establish a decimal integer value that specifies how often (in seconds) the shell shall check for the arrival of mail in the files specified by the MAILPATH or MAIL diables. The default value shall be 600 seconds. If set to zero, the shell shall check before issuing each primary prompt. variable is set, the shell shall inform the user if any of the files named by the variable are created or if any of their modification times change. (See the preceding entry for MAIL for descriptions of mail arrival and user informing.) Each pathname can be followed by ${ }^{\prime} \%{ }^{\prime}$ and a string that shall be subjected to parameter expansion and written to standard error when the modification time changes. If a ' \%' character in the pathname is preceded by a backslash, it shall be treated as a literal ${ }^{\prime} \%^{\prime}$ in the pathname. The default message is unspecified.

The MAILPATH environment variable takes precedence over the MAIL variable.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

## STDERR

Except as otherwise stated (by the descriptions of any invoked utilities or in interactive mode), standard error shall be used only for diagnostic messages.

## OUTPUT FILES

## None.

## EXTENDED DESCRIPTION

UP See Chapter 2. The functionality described in the rest of the EXTENDED DESCRIPTION section shall be provided on implementations that support the User Portability Utilities option (and the rest of this section is not further shaded for this option).

## Command History List

When the sh utility is being used interactively, it shall maintain a list of commands previously entered from the terminal in the file named by the HISTFILE environment variable. The type, size, and internal format of this file are unspecified. Multiple sh processes can share access to the file for a user, if file access permissions allow this; see the description of the HISTFILE environment variable.

## Command Line Editing

When sh is being used interactively from a terminal, the current command and the command history (see $f_{c}$ ) can be edited using vi-mode command line editing. This mode uses commands, described below, similar to a subset of those described in the vi utility. Implementations may offer other command line editing modes corresponding to other editing utilities.
The command set -o vi shall enable vi-mode editing and place sh into vi insert mode (see Command Line Editing (vi-mode) (on page 856)). This command also shall disable any other editing mode that the implementation may provide. The command set $+\mathbf{o} v i$ disables vi-mode editing.

Certain block-mode terminals may be unable to support shell command line editing. If a terminal is unable to provide either edit mode, it need not be possible to set $-\mathbf{o} v i$ when using the shell on this terminal.

In the following sections, the characters crase, interrupt, kill, and end-of-file are those set by the stty utility.

## Command Line Editing (vi-mode)

In $v i$ editing mode, there shall be a distinguished line, the edit line. All the editing operations which modify a line affect the edit line. The edit line is always the newest line in the command history buffer.
With $v i$-mode enabled, sh can be switched between insert mode and command mode.
When in insert mode, an entered character shall be inserted into the command line, except as noted in vi Line Editing Insert Mode (on page 857). Upon entering sh and after termination of the previous command, sh shall be in insert mode.
Typing an escape character shall switch sh into command mode (see vi Line Editing Command Mode (on page 857)). In command mode, an entered character shall either invoke a defined operation, be used as part of a multi-character operation, or be treated as an error. A character that is not recognized as part of an editing command shall terminate any specific editing command and shall alert the terminal. Typing the interrupt character in command mode shall cause sh to terminate command line editing on the current command line, reissue the prompt on
the next line of the terminal, and reset the command history (see $f_{c}$ ) so that the most recently executed command is the previous command (that is, the command that was being edited when it was interrupted is not reentered into the history).
In the following sections, the phrase "move the cursor to the beginning of the word" shall mean "move the cursor to the first character of the current word" and the phrase "move the cursor to the end of the word" shall mean "move the cursor to the last character of the current word". The phrase "beginning of the command line" indicates the point between the end of the prompt string issued by the shell (or the beginning of the terminal line, if there is no prompt string) and the first character of the command text.

## vi Line Editing Insert Mode

While in insert mode, any character typed shall be inserted in the current command line, unless it is from the following set.
<newline> Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see $f_{c}$ ).
erase Delete the character previous to the current cursor position and move the current cursor position back one character. In insert mode, characters shall be erased from both the screen and the buffer when backspacing.
interrupt Terminate command line editing with the same effects as described for interrupting command mode; see Command Line Editing (vi-mode) (on page 856).
kill Clear all the characters from the input line.
<control>-V Insert the next character input, even if the character is otherwise a special insert mode character.
<control>-W Delete the characters from the one preceding the curson to the preceding word boundary. The word boundary in this case is the closer to the cursor of either the beginning of the line or a character that is in neither the blank nor punct character classification of the current locale.
end-of-file Interpreted as the end of input in sh. This interpretation shall occur only at the beginning of an input line. If end-of-file is entered other than at the beginning of the line, the results are unspecified.
<ESC> Place sh into command mode.
vi Line Editing Command Mode
In command mode for the command line editing feature, decimal digits not beginning with 0 that precede a command letter shall be remembered. Some commands use these decimal digits as a count number that affects the operation.
The term motion command represents one of the commands:

If the current line is not the edit line, any command that modifies the current line shall cause the content of the current line to replace the content of the edit line, and the current line shall become the edit line. This replacement cannot be undone (see the $\mathbf{u}$ and $\mathbf{U}$ commands below). The modification requested shall then be performed to the edit line. When the current line is the edit line, the modification shall be done directly to the edit line.

Any command that is preceded by count shall take a count (the numeric value of any preceding decimal digits). Unless otherwise noted, this count shall cause the specified operation to repeat by the number of times specified by the count. Also unless otherwise noted, a count that is out of range is considered an error condition and shall alert the terminal, but neither the cursor
position, nor the command line, shall change.
The terms word and bigword are used as defined in the vi description. The term save buffer corresponds to the term unnamed buffer in vi.

The following commands shall be recognized in command mode:
<newline> Execute the current command line. If the current command line is not empty, this line shall be entered into the command history (see $f_{c}$ ).
<control>-L Redraw the current command line. Position the cursor at the same location on the redrawn line.
\# Insert the character ' \#' at the beginning of the current command line and treat the resulting edit line as a comment. This line shall be entered into the command history; see $f c$.
$=\quad$ Display the possible shell word expansions (see Section 2.6 (on page 37)) of the bigword at the current command line position.
Note: This does not modify the content of the current line, and therefore does not cause the current line to become the edit line.

These expansions shall be displayed on subsequent terminal lines. If the bigword contains none of the characters ' ? ', $\quad$ *', or ' [', an asterisk ( ${ }^{\prime}{ }^{\prime \prime}$ ) shall be implicitly assumed at the end. If any directories are matched, these expansions shall have a '/' character appended. After the expansion, the line shall be redrawn, the cursor repositioned at the current cursor position, and sh shall be placed in command mode.
\ Perform pathname expansion (see Section 2.6 .6 (on page 43)) on the current bigword, up to the largest set of characters that can be matched uniquely. If the bigword contains none of the characters ' $?^{\prime},^{\prime} \star^{\prime}$, or ${ }^{\prime}$ [', an asterisk ( ${ }^{\prime}$ *' $^{\prime}$ ) shall be implicitly assumed at the end. This maximal expansion then shall replace the original bigword in the command line, and the cursor shall be placed after this expansion. If the resulting bigword completely and uniquely matches a directory, a '/' character shall be inserted directly after the bigword. If some other file is completely matched, a single <space> shall be inserted after the bigword. After this operation, sh shall be placed in insert mode.
*
Perform pathname expansion on the current bigword and insert all expansions into the command to replace the current bigword, with each expansion separated by a single <space>. If at the end of the line, the current cursor position shall be moved to the first column position following the expansions and sh shall be placed in insert mode. Otherwise, the current cursor position shall be the last column position of the first character after the expansions and sh shall be placed in insert mode. If the current bigword contains none of the characters ' ?', ' ${ }^{\prime}$, or ' [', before the operation, an asterisk shall be implicitly assumed at the end.
@letter Insert the value of the alias named _letter. The symbol letter represents a single alphabetic character from the portable character set; implementations may support additional characters as an extension. If the alias _letter contains other editing commands, these commands shall be performed as part of the insertion. If no alias _letter is enabled, this command shall have no effect.
[count] Convert, if the current character is a lowercase letter, to the equivalent uppercase letter and vice versa, as prescribed by the current locale. The current cursor position then shall be advanced by one character. If the cursor was positioned on the last character of the line, the case conversion shall occur, but the cursor shall not advance. If the $\boldsymbol{~}^{\sim \prime}$ command is preceded by a count, that number of characters shall be converted, and the cursor shall be advanced to the character position after

| 33917 33918 |  | the last character converted. If the count is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line. |
| :---: | :---: | :---: |
| 33919 | [count]. | Repeat the most recent non-motion command, even if it was executed on an earlier command line. If the previous command was preceded by a count, and no count is given on the '.' command, the count from the previous command shall be included as part of the repeated command. If the '.$^{\prime}$ command is preceded by a count, this shall override any count argument to the previous command. The count specified in the '.' command shall become the count for subsequent '.' commands issued without a count. |
| 33920 |  |  |
| 33921 |  |  |
| 33922 |  |  |
| 33923 |  |  |
| 33924 |  |  |
| 295 |  |  |
| 26 | [number] $\mathbf{v}$ | Invoke the $v i$ editor to edit the current command line in a temporary file. When the editor exits, the commands in the temporary file shall be executed and placed in the command history. If a number is included, it specifies the command number in the command history to be edited, rather than the current command line. |
| 33927 |  |  |
| 3392 |  |  |
| 33929 |  |  |
| 33930 | [count] (ell) |  |
| 33931 | [count]<space> |  |
| 33932 |  | Move the current cursor position to the next character position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the count is larger than the number of characters after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line. |
| 33933 |  |  |
| 33934 |  |  |
| 33935 |  |  |
| 33936 |  |  |
| 33937 | [count]h | Move the current cursor position to the countth (default 1) previous character position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of characters before the cursor, this shall not be considered an error; the cursor shall move to the first character on the line. |
| 3393 |  |  |
| 3393 |  |  |
| 33940 |  |  |
| 941 |  |  |
| 942 | [count]w | Move to the start of the next word. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the count is larger than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line. |
| 33943 |  |  |
| 33944 |  |  |
| 33945 |  |  |
| 33946 |  |  |
| 33947 | [count] W | Move to the start of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the count is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on |
| 33948 |  |  |
| 33949 |  |  |
| 950 |  |  |
| 33951 |  | line. |
| 33952 | [count]e | Move to the end of the current word. If at the end of a word, move to the end of |
| 33953 |  | the next word. If the cursor was positioned on the last character of the line, the |
| 33954 |  | terminal shall be alerted and the cursor shall not be advanced. If the count is larger |
| 33955 |  | than the number of words after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line. |
| 33956 |  |  |
| 33957 | [count] E | Move to the end of the current bigword. If at the end of a bigword, move to the end of the next bigword. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the count is larger than the number of bigwords after the cursor, this shall not be considered an error; the cursor shall advance to the last character on the line. |
| 33958 |  |  |
| 33959 |  |  |
| 33960 |  |  |
| 33961 |  |  |
| 33962 | [count] ${ }^{\text {b }}$ | Move to the beginning of the current word. If at the beginning of a word, move to the beginning of the previous word. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of words preceding the cursor, this |
| 33963 |  |  |
| 33964 |  |  |
| 33965 |  |  |

Shell and Utilities, Issue 7 - Copyright © 2001-200x, IEEE and The Open Group. All rights reserved.

| 33966 33967 |  | shall not be considered an error; the cursor shall return to the first character on line. |
| :---: | :---: | :---: |
| 339 | [count]B | Move to the beginning of the current bigword. If at the beginning of a bigword, move to the beginning of the previous bigword. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of bigwords preceding the cursor, this shall not be considered an error; the cursor shall return to the first character on the line. |
| 33969 |  |  |
| 33970 |  |  |
| 33971 |  |  |
| 33972 |  |  |
| 33973 |  |  |
| 974 |  | Move the current cursor position to the first character on the input line that is not a |
| 33975 |  | <blank> |
| 33976 | \$ | Move to the last character position on the current command line. |
| 33977 | 0 | (Zero.) Move to the first character position on the current command line. |
| 33978 | [count] I | Move to the countth character position on the current command line. If no number is specified, move to the first position. The first character position shall be numbered 1. If the count is larger than the number of characters on the line, this shall not be considered an error; the cursor shall be placed on the last character on the line. |
| 33979 |  |  |
| 33980 |  |  |
| 33981 |  |  |
| 33982 |  |  |
| 33983 | [ count]fc | Move to the first occurrence of the character ' $\mathrm{c}^{\prime}$ ' that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character ' $c^{\prime}$ does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moyed. |
| 33984 |  |  |
| 33985 |  |  |
| 33986 |  |  |
| 33987 |  |  |
| 33988 | [count] ${ }_{\text {c }}$ | Move to the first occurrence of the character ' $\mathrm{c}^{\prime}$ that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character ' $c$ ' does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved. |
| 33989 |  |  |
| 33990 |  |  |
| 33991 |  |  |
| 33992 |  |  |
| 33993 | [count]tc | Move to the character before the first occurrence of the character ' $\mathrm{c}^{\prime}$ that occurs after the current cursor position. If the cursor was positioned on the last character of the line, the terminal shall be alerted and the cursor shall not be advanced. If the character ' $c$ ' does not occur in the line after the current cursor position, the terminal shall be alerted and the cursor shall not be moved. |
| 33994 |  |  |
| 33995 |  |  |
| 33996 |  |  |
| 33997 |  |  |
| 33998 | [count] ${ }_{\text {c }}$ c | Move to the character after the first occurrence of the character ' $C^{\prime}$ ' that occurs before the current cursor position. If the cursor was positioned on the first character of the line, the terminal shall be alerted and the cursor shall not be moved. If the character ' $\mathrm{c}^{\prime}$ does not occur in the line before the current cursor position, the terminal shall be alerted and the cursor shall not be moved. |
| 33999 |  |  |
| 34000 |  |  |
| 34001 |  |  |
| 34002 |  |  |
| 34003 | [count]; | Repeat the most recent $\mathbf{f}, \mathbf{F}, \mathbf{t}$, or $\mathbf{T}$ command. Any number argument on that previous command shall be ignored. Errors are those described for the repeated command. |
| 34004 |  |  |
| 34005 |  |  |
| 34006 | [count], | Repeat the most recent $\mathbf{f}, \mathbf{F}, \mathbf{t}$, or $\mathbf{T}$ command. Any number argument on that previous command shall be ignored. However, reverse the direction of that command. |
| 34007 |  |  |
| 34008 |  |  |
| 34009 | a | Enter insert mode after the current cursor position. Characters that are entered shall be inserted before the next character. |
| 34010 |  |  |
| 34011 | A | Enter insert mode after the end of the current command line |

| 34012 34013 | i | Enter insert mode at the current cursor position. Characters that are entered shall be inserted before the current character. |
| :---: | :---: | :---: |
| 34014 | I | Enter insert mode at the beginning of the current command line. |
| 34015 34016 | R | Enter insert mode, replacing characters from the command line beginning at the current cursor position. |
| 340 | [count]cmotion |  |
| 34018 34019 34020 34021 34022 |  | Delete the characters between the current cursor position and the cursor position that would result from the specified motion command. Then enter insert mode before the first character following any deleted characters. If count is specified, it shall be applied to the motion command. A count shall be ignored for the following motion commands: |
| 34023 |  | \$ |
| 3402 |  | If the motion command is the character ' $\mathrm{c}^{\prime}$ ', the current command line shall be |
| 34025 |  | cleared and insert mode shall be entered. If the motion command would move the |
| 34026 |  | current cursor position toward the beginining of the command line, the character |
| 34027 |  | under the current cursor position shall not be deleted. If the motion command |
| 34028 |  | would move the current cursor position toward the end of the command line, the |
| 34029 |  | character under the current cursor position shall be deleted. If the count is larger |
| 34030 |  | than the number of characters between the current cursor position and the end of |
| 34031 |  | the command line toward which the motion command would move the cursor, this |
| 34032 |  | shall not be considered an error; all of the remaining characters in the |
| 34033 |  | aforementioned range shall be deleted and insert mode shall be entered. If the |
| 34034 |  | motion command is invalid, the terminal shall be alerted, the cursor shall not be |
| 34035 |  | moved, and no text shall be deleted. |
| 34036 | C | Delete from the current character to the end of the line and enter insert mode at the |
| 34037 |  | new end-of-line. |
| 34038 | S | Clear the entire edit line and enter insert mod |
| 34039 | [count]rc Replace the current character with the character ' $\mathrm{c}^{\prime}$ '. With a number count, replace the current and the following count-1 characters. After this command, the current cursor position shall be on the last character that was changed. If the count is larger than the number of characters after the cursor, this shall not be considered an error; all of the remaining characters shall be changed. |  |
| 34040 |  |  |
| 34041 |  |  |
| 34042 |  |  |
| 34043 |  |  |
| 34044 | [count]_ | Append a <space> after the current character position and then append the last bigword in the previous input line after the <space>. Then enter insert mode after the last character just appended. With a number count, append the countth bigword in the previous line. |
| 34045 |  |  |
| 34046 |  |  |
| 047 |  |  |
| 34048 | [count]x | Delete the character at the current cursor position and place the deleted characters in the save buffer. If the cursor was positioned on the last character of the line, the character shall be deleted and the cursor position shall be moved to the previous character (the new last character). If the count is larger than the number of characters after the cursor, this shall not be considered an error; all the characters from the cursor to the end of the line shall be deleted. |
| 34049 |  |  |
| 34050 |  |  |
| 34051 |  |  |
| 34052 |  |  |
| 34053 |  |  |
| 34054 | [count] ${ }^{\text {d }}$ | Delete the character before the current cursor position and place the deleted characters in the save buffer. The character under the current cursor position shall not change. If the cursor was positioned on the first character of the line, the terminal shall be alerted, and the $\mathbf{X}$ command shall have no effect. If the line contained a single character, the $\mathbf{X}$ command shall have no effect. If the line contained no characters, the terminal shall be alerted and the cursor shall not be moved. If the count is larger than the number of characters before the cursor, this |
| 34055 |  |  |
| 34056 |  |  |
| 34057 |  |  |
| 34058 |  |  |
| 34059 |  |  |
| 34060 |  |  |

shall not be considered an error; all the characters from before the cursor to the beginning of the line shall be deleted.
[count]dmotion
Delete the characters between the current cursor position and the character position that would result from the motion command. A number count repeats the motion command count times. If the motion command would move toward the beginning of the command line, the character under the current cursor position shall not be deleted. If the motion command is $\mathbf{d}$, the entire current command line shall be cleared. If the count is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be deleted. The deleted characters shall be placed in the save buffer.
D Delete all characters from the current cursor position to the end of the line. The deleted characters shall be placed in the save buffer.
[count]ymotion
Yank (that is, copy) the characters from the current cursor position to the position resulting from the motion command into the save buffer. A number count shall be applied to the motion command. If the motion command would move toward the beginning of the command line, the character under the current cursor position shall not be included in the set of yanked characters. If the motion command is $\mathbf{y}$, the entire current command line shall be yanked into the save buffer. The current cursor position shall be unchanged. If the count is larger than the number of characters between the current cursor position and the end of the command line toward which the motion command would move the cursor, this shall not be considered an error; all of the remaining characters in the aforementioned range shall be yanked.
Y Yank the characters from the current cursor position to the end of the line into the save buffer. The current character position shall be unchanged.
[count]p
Put a copy of the current contents of the save buffer after the current cursor position. The current cursor position shall be advanced to the last character put from the save buffer. A count shall indicate how many copies of the save buffer shall be put.
[count] P Put a copy of the current contents of the save buffer before the current cursor position. The current cursor position shall be moved to the last character put from the save buffer. A count shall indicate how many copies of the save buffer shall be put.
u Undo the last command that changed the edit line. This operation shall not undo the copy of any command line to the edit line.
$\mathbf{U} \quad$ Undo all changes made to the edit line. This operation shall not undo the copy of any command line to the edit line.
[count] $\mathbf{k}$
[count]- Set the current command line to be the countth previous command line in the shell command history. If count is not specified, it shall default to 1 . The cursor shall be positioned on the first character of the new command. If a $\mathbf{k}$ or - command would retreat past the maximum number of commands in effect for this shell (affected by the HISTSIZE environment variable), the terminal shall be alerted, and the command shall have no effect.
[count] $]$
[count] + Set the current command line to be the countth next command line in the shell command history. If count is not specified, it shall default to 1 . The cursor shall be positioned on the first character of the new command. If a $\mathbf{j}$ or + command advances past the edit line, the current command line shall be restored to the edit line and the terminal shall be alerted.
[number]G Set the current command line to be the oldest command line stored in the shell command history. With a number number, set the current command line to be the command line number in the history. If command line number does not exist, the terminal shall be alerted and the command line shall not be changed.
/pattern<newline>
Move backwards through the command history, searching for the specified pattern, beginning with the previous command line. Patterns use the pattern matching notation described in Section 2.13 (on page 62), except that the ' ^' character shall have special meaning when it appears as the first character of pattern. In this case, the ${ }^{\prime \prime}$ ' is discarded and the characters after the ${ }^{\prime \prime \prime}$ shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal is alerted. If it is found in a previous line, the current command line shall be set to that line and the cursor shall be set to the first character of the new command line.

If pattern is empty, the last non-empty pattern provided to / or ? shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.
?pattern<newline>
Moye forwards through the command history, searching for the specified pattern, beginning with the next command line. Patterns use the pattern matching notation described in Section 2.13 (on page 62), except that the ' $n$ ' character shall have special meaning when it appears as the first character of pattern. In this case, the $\prime \wedge$ is discarded and the characters after the $\prime \prime$ shall be matched only at the beginning of a line. Commands in the command history shall be treated as strings, not as filenames. If the pattern is not found, the current command line shall be unchanged and the terminal alerted. If it is found in a following line, the current command line shall be set to that line and the cursor shall be set to the fist character of the new command line.

If pattern is empty, the last non-empty pattern provided to / or ? shall be used. If there is no previous non-empty pattern, the terminal shall be alerted and the current command line shall remain unchanged.
n Repeat the most recent / or ? command. If there is no previous / or ?, the terminal shall be alerted and the current command line shall remain unchanged.

N
Repeat the most recent / or ? command, reversing the direction of the search. If there is no previous / or ?, the terminal shall be alerted and the current command line shall remain unchanged.

## EXIT STATUS

The following exit values shall be returned:
0 The script to be executed consisted solely of zero or more blank lines or comments, or both.

1-125 A non-interactive shell detected a syntax, redirection, or variable assignment error.
127 A specified command_file could not be found by a non-interactive shell.
Otherwise, the shell shall return the exit status of the last command it invoked or attempted to invoke (see also the exit utility in Section 2.14 (on page 64 )).

## CONSEQUENCES OF ERRORS

See Section 2.8.1 (on page 46).

## APPLICATION USAGE

Standard input and standard error are the files that determine whether a shell is interactive when $-\mathbf{i}$ is not specified. For example:
sh > file
and:
sh 2> file
create interactive and non-interactive shells, respectively. Although both accept terminal input, the results of error conditions are different, as described in Section 2.8.1 (on page 46); in the second example a redirection error encountered by a special built-in utility aborts the shell.

A conforming application must protect its first operand, if it starts with a plus sign, by preceding it with the "--" argument that denotes the end of the options.
Applications should note that the standard PATH to the shell cannot be assumed to be either $/ \mathrm{bin} / \mathrm{sh}$ or $/ \mathrm{usr} / \mathrm{bin} / \mathrm{sh}$, and should be determined by interrogation of the PATH returned by getconf PATH, ensuring that the returned pathname is an absolute pathname and not a shell built-in.

For example, to determine the location of the standard sh utility:

```
command -v sh
```

On some implementations this might return:

```
/usr/xpg4/bin/sh
```

Furthermore, on systems that support executable scripts (the "\#!" construct), it is recommended that applications using executable scripts install them using getconf $-\mathbf{v}$ to determine the shell pathname and update the "\#!" script appropriately as it is being installed (for example, with sed). For example:

```
#
# Installation time script to install correct POSIX shell pathname
#
# Get list of paths to check
#
Sifs=$IFS
IFS=:
set $(getconf PATH)
IFS=$Sifs
#
# Check each path for 'sh'
#
for i in $@
do
    if [ -f ${i}/sh ];
    then
        Pshell=${i}/sh
```

```
            fi
done
#
# This is the list of scripts to update. They should be of the
# form '${name}.source' and will be transformed to '${name}'.
# Each script should begin:
#
# !INSTALLSHELLPATH -p
#
scripts="a b c"
#
# Transform each script
#
for i in ${scripts}
do
    sed -e "s|INSTALLSHELLPATH|${Pshell}|" < ${i}.source > ${i}
done
```

## EXAMPLES

1. Execute a shell command from a string:
```
sh -c "cat myfile"
```

2. Execute a shell script from a file in the current directory:

## RATIONALE

The sh utility and the set special built-in utility share a common set of options.
The name IFS was originally an abbreviation of "Input Field Separators"; however, this name is misleading as the IFS characters are actually used as field terminators. The KornShell ignores the contents of IFS upon entry to the script. A conforming application cannot rely on importing IFS. One justification for this, beyond security considerations, is to assist possible future shell compilers. Allowing IFS to be imported from the environment prevents many optimizations that might otherwise be performed via dataflow analysis of the script itself.

The text in the STDIN section about non-blocking reads concerns an instance of sh that has been invoked, probably by a C-language program, with standard input that has been opened using the O_NONBLOCK flag; see open () in the System Interfaces volume of IEEE Std 1003.1-200x. If the shell did not reset this flag, it would immediately terminate because no input data would be available yet and that would be considered the same as end-of-file.
The options associated with a restricted shell (command name rsh and the $-\mathbf{r}$ option) were excluded because the standard developers considered that the implied level of security could not be achieved and they did not want to raise false expectations.
On systems that support set-user-ID scripts, a historical trapdoor has been to link a script to the name -i. When it is called by a sequence such as:
sh -
or by:

```
#! usr/bin/sh -
```

the historical systems have assumed that no option letters follow. Thus, this volume of IEEE Std 1003.1-200x allows the single hyphen to mark the end of the options, in addition to the use of the regular "--" argument, because it was considered that the older practice was so pervasive. An alternative approach is taken by the KornShell, where real and effective
user/group IDs must match for an interactive shell; this behavior is specifically allowed by this volume of IEEE Std 1003.1-200x.

Note: There are other problems with set-user-ID scripts that the two approaches described here do not resolve.

The initialization process for the history file can be dependent on the system start-up files, in that they may contain commands that effectively preempt the user's settings of HISTFILE and HISTSIZE. For example, function definition commands are recorded in the history file, unless the set -o nolog option is set. If the system administrator includes function definitions in some system start-up file called before the $E N V$ file, the history file is initialized before the user gets a chance to influence its characteristics. In some historical shells, the history file is initialized just after the ENV file has been processed. Therefore, it is implementation-defined whether changes made to HISTFILE after the history file has been initialized are effective.

The default messages for the various MAIL-related messages are unspecified because they vary across implementations. Typical messages are:
"you have mail\n"
or:
"you have new mail\n"
It is important that the descriptions of command line editing refer to the same shell as that in IEEE Std 1003.1-200x so that interactive users can also be application programmers without having to deal with programmatic differences in their two environments. It is also essential that the utility name sh be specified because this explicit utility name is too firmly rooted in historical practice of application programs for it to change.
Consideration was given to mandating a diagnostic message when attempting to set vi-mode on terminals that do not support command line editing. However, it is not historical practice for the shell to be cognizant of all terminal types and thus be able to detect inappropriate terminals in all cases. Implementations are encouraged to supply diagnostics in this case whenever possible, rather than leaving the user in a state where editing commands work incorrectly.

In early proposals, the KornShell-derived emacs mode of command line editing was included, even though the emacs editor itself was not. The community of emacs proponents was adamant that the full emacs editor not be standardized because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship strictly conforming versions lacking the extensibility required by the community. The author of the original emacs program also expressed his desire to omit the program. Furthermore, there were a number of historical systems that did not include emacs, or included it without supporting it, but there were very few that did not include and support $v i$. The shell emacs command line editing mode was finally omitted because it became apparent that the KornShell version and the editor being distributed with the GNU system had diverged in some respects. The author of emacs requested that the POSIX emacs mode either be deleted or have a significant number of unspecified conditions. Although the KornShell author agreed to consider changes to bring the shell into alignment, the standard developers decided to defer specification at that time. At the time, it was assumed that convergence on an acceptable definition would occur for a subsequent draft, but that has not happened, and there appears to be no impetus to do so. In any case, implementations are free to offer additional command line editing modes based on the exact models of editors their users are most comfortable with.

Early proposals had the following list entry in vi Line Editing Insert Mode (on page 857):
\ If followed by the erase or kill character, that character shall be inserted into the input line. Otherwise, the backslash itself shall be inserted into the input line.

However, this is not actually a feature of sh command line editing insert mode, but one of some historical terminal line drivers. Some conforming implementations continue to do this when the
stty iexten flag is set.

## FUTURE DIRECTIONS

None.

Chapter 2 (on page 29), cd, echo, exit, $f c$, pwd, read, set, stty, test, umask, vi, the System Interfaces volume of IEEE Std 1003.1-200x, dup (), exec, exit(), fork(), open(), pipe(), signal(), system(), ulimit( ), umask(), wait ()

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Text is added to the DESCRIPTION for the Large File Summit proposal.
Issue 6
The Open Group Corrigendum U029/2 is applied, correcting the second SYNOPSIS.
The Open Group Corrigendum U027/3 is applied, correcting a typographical error.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The option letters derived from the set special built-in are also accepted with a leading plus sign (' + ' ).
- Large file extensions are added:
- Pathname expansion does not fail due to the size of a file.
- Shell input and output redirections have an implementation-defined offset maximum that is established in the open file description.

In the ENVIRONMENT VARIABLES section, the text "user's home directory" is updated to "directory referred to by the HOME environment variable".

Descriptions for the $E N V$ and $P W D$ environment variables are included to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.

## Issue 7

Austin Group Interpretation 1003.1-2001 \#098 is applied, changing the definition of IFS.
Minor editorial changes are made to the User Portability Utilities option shading. No normative changes are implied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
sleep - suspend execution for an interval

## SYNOPSIS

sleep time

## DESCRIPTION

The sleep utility shall suspend execution for at least the integral number of seconds specified by the time operand.

OPTIONS
None.
OPERANDS
The following operand shall be supported:
time A non-negative decimal integer specifying the number of seconds for which to suspend execution.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of sleep:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
$L C \_C T Y P E$ Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

If the sleep utility receives a SIGALRM signal, one of the following actions shall be taken:

1. Terminate normally with a zero exit status.
2. Effectively ignore the signal.
3. Provide the default behavior for signals described in the ASYNCHRONOUS EVENTS section of Section 1.11 (on page 18). This could include terminating with a non-zero exit status.

The sleep utility shall take the standard action for all other signals.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The execution was successfully suspended for at least time seconds, or a SIGALRM signal was received. See the ASYNCHRONOUS EVENTS section.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

The sleep utility can be used to execute a command after a certain amount of time, as in:
(sleep 105; command) \&
or to execute a command every so often, as in:

```
while true
do
        command
        sleep }3
done
```

## RATIONALE

The exit status is allowed to be zero when sleep is interrupted by the SIGALRM signal because most implementations of this utility rely on the arrival of that signal to notify them that the requested finishing time has been successfully attained. Such implementations thus do not distinguish this situation from the successful completion case. Other implementations are allowed to catch the signal and go back to sleep until the requested time expires or to provide the normal signal termination procedures.
As with all other utilities that take integral operands and do not specify subranges of allowed values, sleep is required by this volume of IEEE Std 1003.1-200x to deal with time requests of up to 2147483647 seconds. This may mean that some implementations have to make multiple calls to the delay mechanism of the underlying operating system if its argument range is less than this.

## FUTURE DIRECTIONS

None.

wait, the System Interfaces volume of IEEE Std 1003.1-200x, alarm (), sleep ()

First released in Issue 2.

34425

NAME
sort - sort, merge, or sequence check text files

## SYNOPSIS

```
sort [-m] [-o output] [-bdfinru] [-t char] [-k keydef]... [file...]
sort -c [-bdfinru] [-t char] [-k keydef] [file]
```

## DESCRIPTION

The sort utility shall perform one of the following functions:

1. Sort lines of all the named files together and write the result to the specified output.
2. Merge lines of all the named (presorted) files together and write the result to the specified output.
3. Check that a single input file is correctly presorted.

Comparisons shall be based on one or more sort keys extracted from each line of input (or, if no sort keys are specified, the entire line up to, but not including, the terminating <newline>), and shall be performed using the collating sequence of the current locale.

## OPTIONS

The sort utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for Guideline 9, and the $-\mathbf{k}$ keydef option should follow the $-\mathbf{b},-\mathbf{d},-\mathbf{f},-\mathbf{i},-\mathbf{n}$, and $-\mathbf{r}$ options. In addition, ${ }^{\prime}+{ }^{\prime}$ may be recognized as an option delimiter as well as ${ }^{\prime}{ }^{\prime}$.
The following options shall be supported:
-c Check that the single input file is ordered as specified by the arguments and the collating sequence of the current locale. No output shall be produced; only the exit code shall be affected.
$-\mathbf{m}$ Merge only; the input file shall be assumed to be already sorted.
-o output Specify the name of an output file to be used instead of the standard output. This file can be the same as one of the input files.
-u Unique: suppress all but one in each set of lines having equal keys. If used with the -c option, check that there are no lines with duplicate keys, in addition to checking that the input file is sorted.
The following options shall override the default ordering rules. When ordering options appear independent of any key field specifications, the requested field ordering rules shall be applied globally to all sort keys. When attached to a specific key (see $-\mathbf{k}$ ), the specified ordering options shall override all global ordering options for that key.
-d Specify that only <blank>s and alphanumeric characters, according to the current setting of LC_CTYPE, shall be significant in comparisons. The behavior is undefined for a sort key to which $\mathbf{- i}$ or $\mathbf{- n}$ also applies.
-f Consider all lowercase characters that have uppercase equivalents, according to the current setting of LC_CTYPE, to be the uppercase equivalent for the purposes of comparison.
-i Ignore all characters that are non-printable, according to the current setting of LC_CTYPE. The behavior is undefined for a sort key for which $-\mathbf{n}$ also applies.

| 34456 | -n | Restrict the sort key to an initial numeric string, consisting of optional <blank>s, |
| :---: | :---: | :---: |
| 34457 |  | optional minus sign, and zero or more digits with an optional radix character and |
| 34458 |  | thousands separators (as defined in the current locale), which shall be sorted by |
| 34459 |  | arithmetic value. An empty digit string shall be treated as zero. Leading zeros and |
| 34460 |  | signs on zeros shall not affect ordering. |
| 34461 | -r | Reverse the sense of comparisons. |
| 34462 | The treatment of field separators can be altered using the options: |  |
| 34463 | -b | Ignore leading <blank>s when determining the starting and ending positions of a |
| 34464 |  | restricted sort key. If the $-\mathbf{b}$ option is specified before the first $-\mathbf{k}$ option, it shall be |
| 34465 |  | applied to all $-\mathbf{k}$ options. Otherwise, the $-\mathbf{b}$ option can be attached independently |
| 34466 |  | to each $\mathbf{- k}$ field_start or field_end option-argument (see below). |
| 34467 | -t char | Use char as the field separator character; char shall not be considered to be part of a field (although it can be included in a sort key). Each occurrence of char shall be significant (for example, <char><char> delimits an empty field). If $-\mathbf{t}$ is not specified, <blank>s shall be used as default field separators; each maximal nonempty sequence of <blank>s that follows a non-<blank> shall be a field separator. |
| 34468 |  |  |
| 34469 |  |  |
| 34470 |  |  |
| 34471 |  |  |
| 34472 | Sort keys can be specified using the options: |  |
| 34473 | -k keyde | The keydef argument is a restricted sort key field definition. The format of this definition is: |
| 34474 |  |  |
| 34475 |  | field_start[type][, field_end[typ |
| 34476 |  | where field_start and field_end define a key field restricted to a portion of the line |
| 34477 |  | (see the EXTENDED DESCRIPTION section), and type is a modifier from the list of |
| 34478 |  | characters 'b', 'd', 'f', 'i', 'n', 'r'. The 'b' modifier shall behave like the |
| 34479 |  | -b option, but shall apply only to the field_start or field_end to which it is attached. |
| 34480 |  | The other modifiers shall behave like the corresponding options, but shall apply |
| 34481 |  | only to the key field to which they are attached; they shall have this effect if |
| 34482 |  | specified with field_start, field_end, or both. If any modifier is attached to a |
| 34483 |  | field_start or to a field_end, no option shall apply to either. Implementations shall |
| 34484 |  | support at least nine occurrences of the -k option, which shall be significant in |
| 34485 |  | mmand line order. If no -k option is specified, a default sort key of the entire |
| 34486 |  | shall be used. |
| 34487 |  | When there are multiple key fields, later keys shall be compared only after all |
| 34488 |  | earlier keys compare equal. Except when the -u option is specified, lines that |
| 34489 |  | otherwise compare equal shall be ordered as if none of the options $-\mathbf{d},-\mathbf{f},-\mathbf{i},-\mathbf{n}$, or |
| 34490 |  | -k were present (but with -r still in effect, if it was specified) and with all bytes in |
| 34491 |  | the lines significant to the comparison. The order in which lines that still compare |
| 34492 |  | equal are written is unspecified. |

## OPERANDS

The following operand shall be supported:
file A pathname of a file to be sorted, merged, or checked. If no file operands are specified, or if a file operand is ' - ', the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified, or if a file operand is ' $\mathbf{~}^{\prime}$. See the INPUT FILES section.

INPUT FILES
The input files shall be text files, except that the sort utility shall add a <newline> to the end of a file ending with an incomplete last line.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of sort:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for ordering rules.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classification for the -b, $-\mathbf{d},-\mathbf{f},-\mathbf{i}$, and $-\mathbf{n}$ options.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

## LC_NUMERIC

Determine the locale for the definition of the radix character and thousands separator for the -n option.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Unless the -o or -c options are in effect, the standard output shall contain the sorted input.

## STDERR

The standard error shall be used for diagnostic messages. A warning message about correcting an incomplete last line of an input file may be generated, but need not affect the final exit status.

## OUTPUT FILES

If the -o option is in effect, the sorted input shall be written to the file output.

## EXTENDED DESCRIPTION

The notation:
-k field_start[type][,field_end[type]]
shall define a key field that begins at field_start and ends at field_end inclusive, unless field_start falls beyond the end of the line or after field_end, in which case the key field is empty. A missing field_end shall mean the last character of the line.
A field comprises a maximal sequence of non-separating characters and, in the absence of option $-\mathbf{t}$, any preceding field separator.
The field_start portion of the keydef option-argument shall have the form:
field_number[.first_character]
Fields and characters within fields shall be numbered starting with 1 . The field_number and first_character pieces, interpreted as positive decimal integers, shall specify the first character to
be used as part of a sort key. If .first_character is omitted, it shall refer to the first character of the field.

The field_end portion of the keydef option-argument shall have the form:
field_number[.last_character]
The field_number shall be as described above for field_start. The last_character piece, interpreted as a non-negative decimal integer, shall specify the last character to be used as part of the sort key. If last_character evaluates to zero or .last_character is omitted, it shall refer to the last character of the field specified by field_number.

If the $-\mathbf{b}$ option or $\mathbf{b}$ type modifier is in effect, characters within a field shall be counted from the first non-<blank> in the field. (This shall apply separately to first_character and last_character.)

## EXIT STATUS

The following exit values shall be returned:
0 All input files were output successfully, or -c was specified and the input file was correctly sorted.

1 Under the -c option, the file was not ordered as specified, or if the $-\mathbf{c}$ and $-\mathbf{u}$ options were both specified, two input lines were found with equal keys.
$>1$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The default value for $-\mathbf{t}$, <blank>, has different properties from, for example, $-\mathbf{t}$ "<space>". If a line contains:

```
<space><space>foo
```

the following treatment would occur with default separation as opposed to specifically selecting a <space>:

| Field | Default | $-\mathbf{t}$ "<space>" |
| :---: | :--- | :--- |
| 1 | $<$ space $><$ space $>$ foo | empty |
| 2 | empty | empty |
| 3 | empty | foo |

The leading field separator itself is included in a field when $-\mathbf{t}$ is not used. For example, this command returns an exit status of zero, meaning the input was already sorted:

```
sort -c -k 2 <<eof
y<tab>b
x<space>a
eof
```

(assuming that a <tab> precedes the <space> in the current collating sequence). The field separator is not included in a field when it is explicitly set via $-\mathbf{t}$. This is historical practice and allows usage such as:

```
sort -t "|" -k 2n <<eof
Atlanta|425022|Georgia
Birmingham|284413|Alabama
Columbia|100385|South Carolina
eof
```

where the second field can be correctly sorted numerically without regard to the non-numeric field separator.

The wording in the OPTIONS section clarifies that the $-\mathbf{b},-\mathbf{d},-\mathbf{f},-\mathbf{i},-\mathbf{n}$, and $-\mathbf{r}$ options have to come before the first sort key specified if they are intended to apply to all specified keys. The way it is described in this volume of IEEE Std 1003.1-200x matches historical practice, not historical documentation. The results are unspecified if these options are specified after a $-\mathbf{k}$ option.

The -f option might not work as expected in locales where there is not a one-to-one mapping between an uppercase and a lowercase letter.

## EXAMPLES

1. The following command sorts the contents of infile with the second field as the sort key:
sort -k 2,2 infile
2. The following command sorts, in reverse order, the contents of infile1 and infile2, placing the output in outfile and using the second character of the second field as the sort key (assuming that the first character of the second field is the field separator):
sort -r -o outfile -k 2.2,2.2 infile1 infile2
3. The following command sorts the contents of infile1 and infile2 using the second non-<blank> of the second field as the sort key:
```
sort -k 2.2b,2.2b infile1 infile2
```

4. The following command prints the System V password file (user database) sorted by the numeric user ID (the third colon-separated field):
sort -t : -k 3,3n/etc/passwd
5. The following command prints the lines of the already sorted file infile, suppressing all but one occurrence of lines having the same third field:

$$
\text { sort }-u m-k 3.1,3.0 \text { infile }
$$

## RATIONALE

Examples in some historical documentation state that options -um with one input file keep the first in each set of lines with equal keys. This behavior was deemed to be an implementation artifact and was not standardized.

The -z option was omitted; it is not standard practice on most systems and is inconsistent with using sort to sort several files individually and then merge them together. The text concerning -z in historical documentation appeared to require implementations to determine the proper buffer length during the sort phase of operation, but not during the merge.
The $-\mathbf{y}$ option was omitted because of non-portability. The $-\mathbf{M}$ option, present in System V, was omitted because of non-portability in international usage.
An undocumented $-\mathbf{T}$ option exists in some implementations. It is used to specify a directory for intermediate files. Implementations are encouraged to support the use of the TMPDIR environment variable instead of adding an option to support this functionality.
The $\mathbf{- k}$ option was added to satisfy two objections. First, the zero-based counting used by sort is not consistent with other utility conventions. Second, it did not meet syntax guideline requirements.
Historical documentation indicates that "setting -n implies -b". The description of $-\mathbf{n}$ already states that optional leading <blank>s are tolerated in doing the comparison. If $-\mathbf{b}$ is enabled, rather than implied, by $-\mathbf{n}$, this has unusual side effects. When a character offset is used in a column of numbers (for example, to sort modulo 100), that offset is measured relative to the most significant digit, not to the column. Based upon a recommendation from the author of the original sort utility, the $-\mathbf{b}$ implication has been omitted from this volume of

IEEE Std 1003.1-200x, and an application wishing to achieve the previously mentioned side effects has to code the $-\mathbf{b}$ flag explicitly.
Earlier versions of this standard allowed the -o option to appear after operands. Historical practice allowed all options to be interspersed with operands. This version of the standard allows implementations to accept options after operands but conforming applications should not use this form.

Earlier versions of this standard also allowed the -number and +number options. These options are no longer specified by this standard but may be present in some implementations.

NAME
split — split files into pieces

## SYNOPSIS

```
split [-l line_count] [-a suffix_length] [file[name]]
split -b n[k|m] [-a suffix_length] [file[name]]
```

## DESCRIPTION

The split utility shall read an input file and write one or more output files. The default size of each output file shall be 1000 lines. The size of the output files can be modified by specification of the $-\mathbf{b}$ or $-\mathbf{l}$ options. Each output file shall be created with a unique suffix. The suffix shall consist of exactly suffix_length lowercase letters from the POSIX locale. The letters of the suffix shall be used as if they were a base-26 digit system, with the first suffix to be created consisting of all ' $a^{\prime}$ characters, the second with $a$ ' $b$ ' replacing the last ' $a$ ', and so on, until a name of all ' $z$ ' characters is created. By default, the names of the output files shall be ' $x$ ', followed by a two-character suffix from the character set as described above, starting with "aa", "ab", "ac", and so on, and continuing until the suffix " zz ", for a maximum of 676 files.
If the number of files required exceeds the maximum allowed by the suffix length provided, such that the last allowable file would be larger than the requested size, the split utility shall fail after creating the last file with a valid suffix; split shall not delete the files it created with valid suffixes. If the file limit is not exceeded, the last file created shall contain the remainder of the input file, and may be smaller than the requested size.

## OPTIONS

The split utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

$$
\begin{aligned}
& \text {-a suffix_length } \\
& \begin{array}{l}
\text { Use suffix_length letters to form the suffix portion of the filenames of the split file. If } \\
\text {-a is not specified, the default suffix length shall be two. If the sum of the name } \\
\text { operand and the suffix_length option-argument would create a filename exceeding } \\
\text { INAME_MAX\} bytes, an error shall result, split shall exit with a diagnostic message } \\
\text { and no files shall be created. } \\
\text {-b } n \\
-\mathbf{b} n \mathbf{k}
\end{array} \quad \begin{array}{l}
\text { Split a file into pieces } n \text { bytes in size. }
\end{array} \\
& -\mathbf{b} n \mathbf{m}
\end{aligned} \begin{aligned}
& \text { Split a file into pieces } n^{*} 1024 \text { bytes in size. } \\
& -\mathbf{l} \text { line_count } \begin{array}{l}
\text { Specify the number of lines in each resulting file piece. The line_count argument is } \\
\text { an unsigned decimal integer. The default is } 1000 \text {. If the input does not end with a } \\
\text { <newline>, the partial line shall be included in the last output file. }
\end{array}
\end{aligned}
$$

## OPERANDS

The following operands shall be supported:
file The pathname of the ordinary file to be split. If no input file is given or file is ' $\quad$ ', the standard input shall be used.
name The prefix to be used for each of the files resulting from the split operation. If no name argument is given, ' $x$ ' shall be used as the prefix of the output files. The combined length of the basename of prefix and suffix_length cannot exceed \{NAME_MAX\} bytes. See the OPTIONS section.

## STDIN

See the INPUT FILES section.

## INPUT FILES

Any file can be used as input.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of split:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.
OUTPUT FILES
The output files contain portions of the original input file; otherwise, unchanged.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

In the following examples foo is a text file that contains 5000 lines.

1. Create five files, $\mathbf{x a a}, \mathbf{x a b}, \mathbf{x a c}, \mathbf{x a d}$, and $\mathbf{x a e}:$
split foo
2. Create five files, but the suffixed portion of the created files consists of three letters, xaaa, xaab, xaac, xaad, and xaae:
```
split -a 3 foo
```

3. Create three files with four-letter suffixes and a supplied prefix, bar_aaaa, bar_aaab, and bar_aaac:
split -a 4-1 2000 foo bar_
4. Create as many files as are necessary to contain at most $20^{*} 1024$ bytes, each with the default prefix of $\mathbf{x}$ and a five-letter suffix:
```
split -a 5 -b 20k foo
```

## RATIONALE

The $\mathbf{- b}$ option was added to provide a mechanism for splitting files other than by lines. While most uses of the -b option are for transmitting files over networks, some believed it would have additional uses.
The -a option was added to overcome the limitation of being able to create only 676 files.
Consideration was given to deleting this utility, using the rationale that the functionality provided by this utility is available via the csplit utility (see csplit). Upon reconsideration of the purpose of the User Portability Utilities option, it was decided to retain both this utility and the csplit utility because users use both utilities and have historical expectations of their behavior. Furthermore, the splitting on byte boundaries in split cannot be duplicated with the historical csplit.
The text "split shall not delete the files it created with valid suffixes" would normally be assumed, but since the related utility, csplit, does delete files under some circumstances, the historical behavior of split is made explicit to avoid misinterpretation.
Earlier versions of this standard allowed a -line_count option. This form is no longer specified by this standard but may be present in some implementations.

## FUTURE DIRECTIONS

None.

csplit

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
The obsolescent SYNOPSIS is removed.
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied.
The split utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
strings - find printable strings in files

## SYNOPSIS

```
strings [-a] [-t format] [-n number] [file...]
```

## DESCRIPTION

The strings utility shall look for printable strings in regular files and shall write those strings to standard output. A printable string is any sequence of four (by default) or more printable characters terminated by a <newline> or NUL character. Additional implementation-defined strings may be written; see localedef.
If the first argument is ${ }^{\prime}{ }^{\prime}$, the results are unspecified.

## OPTIONS

The strings utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for the unspecified usage of ${ }^{\prime} \mathbf{~}^{\prime}$.

The following options shall be supported:
-a Scan files in their entirety. If -a is not specified, it is implementation-defined what portion of each file is scanned for strings.
-n number Specify the minimum string length, where the number argument is a positive decimal integer. The default shall be 4 .
-t format Write each string preceded by its byte offset from the start of the file. The format shall be dependent on the single character used as the format option-argument:
d The offset shall be written in decimal.

- The offset shall be written in octal.
x The offset shall be written in hexadecimal.

## OPERANDS

The following operand shall be supported:
file A pathname of a regular file to be used as input. If no file operand is specified, the strings utility shall read from the standard input.

## STDIN

See the INPUT FILES section.

## INPUT FILES

The input files named by the utility arguments or the standard input shall be regular files of any format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of strings:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and to identify printable strings.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Strings found shall be written to the standard output, one per line.
When the $-\mathbf{t}$ option is not specified, the format of the output shall be:
"\%s", <string>
With the $-\mathbf{t} \mathbf{o}$ option, the format of the output shall be:
"\% \% \%", <byte offset>, <string>
With the $-\mathbf{t} \mathbf{x}$ option, the format of the output shall be:
"\%x \%s", <byte offset>, <string>
With the $-\mathbf{t} \mathbf{d}$ option, the format of the output shall be:
"\%d \%s", <byte offset>, <string>

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

By default the data area (as opposed to the text, "bss", or header areas) of a binary executable file is scanned. Implementations document which areas are scanned.

Some historical implementations do not require NUL or <newline> terminators for strings to permit those languages that do not use NUL as a string terminator to have their strings written.

## EXAMPLES

None.

## RATIONALE

Apart from rationalizing the option syntax and slight difficulties with object and executable binary files, strings is specified to match historical practice closely. The $-\mathbf{a}$ and $-\mathbf{n}$ options were introduced to replace the non-conforming - and -number options. These options are no longer specified by this standard but may be present in some implementations.

The -o option historically means different things on different implementations. Some use it to mean "offset in decimal", while others use it as "offset in octal". Instead of trying to decide which way would be least objectionable, the $-\mathbf{t}$ option was added. It was originally named $-\mathbf{O}$ to mean "offset", but was changed to -t to be consistent with od.

The ISO C standard function isprint () is restricted to a domain of unsigned char. This volume of IEEE Std 1003.1-200x requires implementations to write strings as defined by the current locale.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The obsolescent SYNOPSIS is removed.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying the behavior if the first argument is ' ${ }^{\prime}$.

The strings utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
strip — remove unnecessary information from strippable files (DEVELOPMENT)

## SYNOPSIS

## NAME

```
sD strip file...
```

## DESCRIPTION

xsi A strippable file is defined as a relocatable, object, or executable file. On XSI-conformant systems, a strippable file can also be an archive of object or relocatable files.
The strip utility shall remove from strippable files named by the file operands any information the implementor deems unnecessary for execution of those files. The nature of that information is unspecified. The effect of strip on object and executable files shall be similar to the use of the
xsi -s option to c99 or fort77. The effect of strip on an archive of object files shall be similar to the use of the -s option to c 99 or fort 77 for each object file in the archive.

## OPTIONS

None.
OPERANDS
The following operand shall be supported:
file A pathname referring to a strippable file.

## STDIN

Not used.

## INPUT FILES

The input files shall be in the form of strippable files successfully produced by any compiler xsi defined by this volume of IEEE Std 1003.1-200x or produced by creating or updating an archive of such files using the ar utility.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of strip:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

STDOUT

## STDERR

OUTPUT FILES

EXIT STATUS

## EXAMPLES

## RATIONALE

## SEE ALSO

Issue 6

Issue 7

Not used.

The standard error shall be used only for diagnostic messages.

The strip utility shall produce strippable files of unspecified format.

## EXTENDED DESCRIPTION

None.

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

None.

None.

Historically, this utility has been used to remove the symbol table from a strippable file. It was included since it is known that the amount of symbolic information can amount to several megabytes; the ability to remove it in a portable manner was deemed important, especially for smaller systems.
The behavior of strip on object and executable files is said to be the same as the -s option to a compiler. While the end result is essentially the same, it is not required to be identical.

XSI-conformant systems support use of strip on archive files containing object files or relocatable files.

## FUTURE DIRECTIONS

None.
ar, c99, fort77

## CHANGE HISTORY

First released in Issue 2.

This utility is marked as part of the Software Development Utilities option.

Austin Group Interpretation 1003.1-2001 \#103 is applied.

## NAME

stty - set the options for a terminal

## SYNOPSIS

```
stty [-a |-g]
    stty operands
```

## DESCRIPTION

The stty utility shall set or report on terminal I/O characteristics for the device that is its standard input. Without options or operands specified, it shall report the settings of certain characteristics, usually those that differ from implementation-defined defaults. Otherwise, it shall modify the terminal state according to the specified operands. Detailed information about the modes listed in the first five groups below are described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. Operands in the Combination Modes group (see Combination Modes (on page 890)) are implemented using operands in the previous groups. Some combinations of operands are mutually-exclusive on some terminal types; the results of using such combinations are unspecified.

Typical implementations of this utility require a communications line configured to use the termios interface defined in the System Interfaces volume of IEEE Std 1003.1-200x. On systems where none of these lines are available, and on lines not currently configured to support the termios interface, some of the operands need not affect terminal characteristics.

## OPTIONS

The stty utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a Write to standard output all the current settings for the terminal.
-g Write to standard output all the current settings in an unspecified form that can be used as arguments to another invocation of the stty utility on the same system. The form used shall not contain any characters that would require quoting to avoid word expansion by the shell; see Section 2.6 (on page 37).

## OPERANDS

The following operands shall be supported to set the terminal characteristics.

## Control Modes

parenb (-parenb) Enable (disable) parity generation and detection. This shall have the effect of setting (not setting) PARENB in the termios c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
parodd (-parodd)
Select odd (even) parity. This shall have the effect of setting (not setting) PARODD in the termios c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
cs5 cs6 cs7 cs8 Select character size, if possible. This shall have the effect of setting CS5, CS6, CS7, and CS8, respectively, in the termios c_cflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.

| 35007 35008 | number | Set terminal baud rate to the number given, if possible. If the baud rate is set to zero, the modem control lines shall no longer be asserted. This shall have |
| :---: | :---: | :---: |
| 35009 |  | the effect of setting the input and output termios baud rate values as defined |
| 35010 |  | in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General |
| 35011 |  | Terminal Interface. |
| 35012 | ispeed number | Set terminal input baud rate to the number given, if possible. If the input baud |
| 3501 |  | rate is set to zero, the input baud rate shall be specified by the value of the |
| 35014 |  | output baud rate. This shall have the effect of setting the input termios baud |
| 35015 |  | rate values as defined in the Base Definitions volume of IEEE Std 1003.1-200x, |
| 35016 |  | Chapter 11, General Terminal Interface. |
| 35017 | ospeed number | Set terminal output baud rate to the number given, if possible. If the output |
| 18 |  | baud rate is set to zero, the modem control lines shall no longer be asserted. |
| 35019 |  | This shall have the effect of setting the output termios baud rate values as |
| 35020 |  | defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, |
| 35021 |  | General Terminal Interface. |
| 35022 | hupcl (-hupcl) | Stop asserting modem control lines (do not stop asserting modem control |
| 35023 |  | lines) on last close. This shall have the effect of setting (not setting) HUPCL in |
| 24 |  | the termios c_cflag field, as defined in the Base Definitions volume of |
| 35025 |  | IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35026 | hup (-hup) | Equivalent to hupcl(-hupcl). |
| 227 | cstopb (-cstopb) | Use two (one) stop bits per character. This shall have the effect of setting (not |
| 35028 |  | setting) CSTOPB in the termios c_cflag field, as defined in the Base Definitions |
| 35029 |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35030 | cread (-cread) | Enable (disable) the receiver. This shall have the effect of setting (not setting) |
| 35031 |  | CREAD in the termios c_cflag field, as defined in the Base Definitions volume |
| 35032 |  | of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 3503 | clocal (-clocal) | Assume a line without (with) modem control. This shall have the effect of |
| 35034 |  | setting (not setting) CLOCAL in the termios c_cflag field, as defined in the |
| 35035 |  | Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General |
| 35036 |  | minal Interface. |
| 35037 | unspecified w | whether stty shall report an error if an attempt to set a Control Mode fails. |
| 35038 | des |  |
| 35039 | ignbrk (-ignbrk) | Ignore (do not ignore) break on input. This shall have the effect of setting (not |
| 35040 |  | setting) IGNBRK in the termios $c_{\text {_ iflag field, as defined in the Base Definitions }}$ |
| 35041 |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35042 | brkint (-brkint) | Signal (do not signal) INTR on break. This shall have the effect of setting (not setting) BRKINT in the termios c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35043 |  |  |
| 35044 |  |  |
| 35045 | ignpar (-ignpar) | Ignore (do not ignore) bytes with parity errors. This shall have the effect of setting (not setting) IGNPAR in the termios $c_{-}$iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35046 |  |  |
| 35047 |  |  |
| 35048 |  |  |
| 35049 | parmrk (-parmrk) |  |
| 35050 |  | Mark (do not mark) parity errors. This shall have the effect of setting (not |
| 35051 |  | setting) PARMRK in the termios c_iflag field, as defined in the Base Definitions |
| 052 |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |

| 35053 |  | inpck (-inpck) | Enable (disable) input parity checking. This shall have the effect of setting (not |
| :---: | :---: | :---: | :---: |
| 35054 |  |  | setting) INPCK in the termios c_iflag field, as defined in the Base Definitions |
| 35055 |  |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35056 |  | istrip (-istrip) | Strip (do not strip) input characters to seven bits. This shall have the effect of |
| 35057 |  |  | setting (not setting) ISTRIP in the termios c_iflag field, as defined in the Base |
| 35058 |  |  | Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal |
| 35059 |  |  | Interface. |
| 35060 |  | inlcr (-inlcr) | Map (do not map) NL to CR on input. This shall have the effect of setting (not |
| 35061 |  |  | setting) INLCR in the termios c_iflag field, as defined in the Base Definitions |
| 35062 |  |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35063 |  | igncr (-igncr) | Ignore (do not ignore) CR on input. This shall have the effect of setting (not |
| 35064 |  |  | setting) IGNCR in the termios c_iflag field, as defined in the Base Definitions |
| 35065 |  |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35066 |  | icrnl (-icrnl) | Map (do not map) CR to NL on input. This shall have the effect of setting (not |
| 35067 |  |  | setting) ICRNL in the termios c_iflag field, as defined in the Base Definitions |
| 35068 |  |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35069 |  | ixon (-ixon) | Enable (disable) START/STOP output control. Output from the system is |
| 35070 |  |  | stopped when the system receives STOP and started when the system receives |
| 35071 |  |  | START. This shall have the effect of setting (not setting) IXON in the termios |
| 35072 |  |  | c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, |
| 35073 |  |  | Chapter 11, General Terminal Interface. |
| 35074 | XSI | ixany (-ixany) | Allow any character to restart output. This shall have the effect of setting (not |
| 35075 |  |  | setting) IXANY in the termios c_iflag field, as defined in the Base Definitions |
| 35076 |  |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35077 |  | ixoff (-ixoff)Output Modesopost (-opost) | Request that the system send (not send) STOP characters when the input queue is nearly full and START characters to resume data transmission. This shall have the effect of setting (not setting) IXOFF in the termios c_iflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35078 |  |  |  |
| 35079 |  |  |  |
| 35080 |  |  |  |
| 35081 |  |  |  |
| 35082 |  |  |  |
| 35083 |  |  | Post-process output (do not post-process output; ignore all other output |
| 35084 |  |  | modes). This shall have the effect of setting (not setting) OPOST in the termios |
| 35085 |  |  | c_oflag field, as defined in the Base Definitions volume of |
| 35086 |  |  | IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35087 | XSI | ocrnl (-ocrnl) | Map (do not map) CR to NL on output This shall have the effect of setting (not |
| 35088 |  |  | setting) OCRNL in the termios c_oflag field, as defined in the Base Definitions |
| 35089 |  |  | volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35090 |  | onocr (-onocr) | Do not (do) output CR at column zero. This shall have the effect of setting (not setting) ONOCR in the termios c_oflag field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. |
| 35091 |  |  |  |
| 35092 |  |  |  |
| 35093 |  | onlret (-onlret) | The terminal newline key performs (does not perform) the CR function. This |
| 35094 |  |  | shall have the effect of setting (not setting) ONLRET in the termios c_oflag |
| 35095 |  |  | field, as defined in the Base Definitions volume of IEEE Std 1003.1-200x, |
| 35096 |  |  | Chapter 11, General Terminal Interface. |
| 35097 |  | ofill (-ofill) | Use fill characters (use timing) for delays. This shall have the effect of setting |
| 35098 |  |  | (not setting) OFILL in the termios c_oflag field, as defined in the Base |
| 35099 |  |  | Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal |

$\left.\begin{array}{lll}35100 & & \text { Interface. } \\ 35101 \\ 35102 & \text { ofdel (-ofdel) } & \begin{array}{l}\text { Fill characters are DELs (NULs). This shall have the effect of setting (not } \\ 35103\end{array} \\ \text { setting) OFDEL in the termios c_oflag field, as defined in the Base Definitions } \\ \text { volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface. }\end{array}\right\}$

| 35145 | echo (-echo) | Echo back (do not echo back) every character typed. This shall have the effect <br> of setting (not setting) ECHO in the termios c-lflag field, as defined in the Base |

Table 4-19 Control Character Names in stty

| Control Character | c_cc Subscript | Description |
| :--- | :--- | :--- |
| eof | VEOF | EOF character |
| eol | VEOL | EOL character |
| erase | VERASE | ERASE character |
| intr | VINTR | INTR character |
| kill | VKILL | KILL character |
| quit | VQUIT | QUIT character |
| susp | VSUSP | SUSP character |
| start | VSTART | START character |
| stop | VSTOP | STOP character |

If string is a single character, the control character shall be set to that character. If string is the two-character sequence " ${ }^{\wedge}-$ " or the string undef, the control character shall be set to _POSIX_VDISABLE , if it is in effect for the device; if _POSIX_VDISABLE is not in effect for
the device, it shall be treated as an error. In the POSIX locale, if string is a two-character sequence beginning with circumflex ( ${ }^{\wedge} \wedge^{\prime}$ ), and the second character is one of those listed in the "^c" column of the following table, the control character shall be set to the corresponding character value in the Value column of the table.

Table 4-20 Circumflex Control Characters in stty

| ${ }^{\text {c }}$ | Value | ${ }^{\text {c }}$ | Value | ${ }^{\text {c }}$ | Value |
| :---: | :---: | :---: | :---: | :---: | :---: |
| a, A | <SOH> | 1, L | <FF> | W, W | <ETB> |
| b, B | <STX> | m, M | <CR> | x, X | <CAN> |
| c, C | <ETX> | n, N | <SO> | y, Y | <EM> |
| d, D | <EOT> | $\bigcirc$ O, | <SI> | z, Z | <SUB> |
| e, E | <ENQ> | $\mathrm{p}, \mathrm{P}$ | <DLE> | [ | <ESC> |
| f, F | <ACK> | q, Q | <DC1> | 1 | <FS> |
| g, G | <BEL> | r, R | <DC2> | ] | <GS> |
| h, H | <BS> | s, S | <DC3> | - | <RS> |
| i, I | <HT> | t, T | <DC4> | - | <US> |
| j, J | <LF> | u, U | <NAK> | ? | <DEL> |
| k, K | <VT> | v, V | <SYN> |  |  |

## min number

Set the value of MIN to number. MIN is used in non-canonical mode input processing (icanon).

## time number

Set the value of TIME to number. TIME is used in non-canonical mode input processing (icanon).

## Combination Modes

saved settings
Set the current terminal characteristics to the saved settings produced by the $-\mathbf{g}$ option.
evenp or parity
Enable parenb and cs7; disable parodd.
oddp
Enable parenb, cs7, and parodd.
-parity,-evenp, or -oddp
Disable parenb, and set cs8.

```
raw (-raw or cooked)
```

Enable (disable) raw input and output. Raw mode shall be equivalent to setting:
stty cs8 erase ^- kill ^- intr ^-
quit ^- eof ^- eol ^- -post -inpck
nl (-nl)
Disable (enable) icrnl. In addition, -nl unsets inlcr and igncr.
ek Reset ERASE and KILL characters back to system defaults.
sane
Reset all modes to some reasonable, unspecified, values.

## STDIN

Although no input is read from standard input, standard input shall be used to get the current terminal I/O characteristics and to set new terminal I/O characteristics.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of stty:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE This variable determines the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and which characters are in the class print.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If operands are specified, no output shall be produced.
If the -g option is specified, stty shall write to standard output the current settings in a form that can be used as arguments to another instance of stty on the same system.

If the -a option is specified, all of the information as described in the OPERANDS section shall be written to standard output. Unless otherwise specified, this information shall be written as <space>-separated tokens in an unspecified format, on one or more lines, with an unspecified number of tokens per line. Additional information may be written.
If no options or operands are specified, an unspecified subset of the information written for the -a option shall be written.
If speed information is written as part of the default output, or if the -a option is specified and if the terminal input speed and output speed are the same, the speed information shall be written as follows:

```
"speed %d baud;", <speed>
```

Otherwise, speeds shall be written as:

```
"ispeed %d baud; ospeed %d baud;", <ispeed>, <ospeed>
```

In locales other than the POSIX locale, the word baud may be changed to something more appropriate in those locales.
If control characters are written as part of the default output, or if the -a option is specified, control characters shall be written as:
"\%s = \%s;", <control-character name>, <value>
where <value> is either the character, or some visual representation of the character if it is non-
printable, or the string undef if the character is disabled.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The terminal options were read or set successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The -g flag is designed to facilitate the saving and restoring of terminal state from the shell level. For example, a program may:

```
saveterm="$(stty -g)" # save terminal state
stty (new settings) # set new state
... # ...
stty $saveterm # restore terminal state
```

Since the format is unspecified, the saved value is not portable across systems.
Since the -a format is so loosely specified, scripts that save and restore terminal settings should use the -g option.

## EXAMPLES

None.

## RATIONALE

The original stty description was taken directly from System V and reflected the System V terminal driver termio. It has been modified to correspond to the terminal driver termios.

Output modes are specified only for XSI-conformant systems. All implementations are expected to provide stty operands corresponding to all of the output modes they support.
The stty utility is primarily used to tailor the user interface of the terminal, such as selecting the preferred ERASE and KILD characters. As an application programming utility, stty can be used within shell scripts to alter the terminal settings for the duration of the script.
The termios section states that individual disabling of control characters is possible through the option _POSIX_VDISABLE. If enabled, two conventions currently exist for specifying this: System V uses "^-", and BSD uses undef. Both are accepted by stty in this volume of IEEE Std 1003.1-200x. The other BSD convention of using the letter ' $u$ ' was rejected because it conflicts with the actual letter ' $u$ ', which is an acceptable value for a control character.

Early proposals did not specify the mapping of " c " to control characters because the control characters were not specified in the POSIX locale character set description file requirements. The control character set is now specified in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 3, Definitions so the historical mapping is specified. Note that although the mapping corresponds to control-character key assignments on many terminals that use the ISO/IEC 646: 1991 standard (or ASCII) character encodings, the mapping specified here is to the control characters, not their keyboard encodings.

Since termios supports separate speeds for input and output, two new options were added to specify each distinctly.
Some historical implementations use standard input to get and set terminal characteristics; others use standard output. Since input from a login TTY is usually restricted to the owner while output to a TTY is frequently open to anyone, using standard input provides fewer chances of accidentally (or maliciously) altering the terminal settings of other users. Using standard input also allows stty -a and stty -g output to be redirected for later use. Therefore, usage of standard input is required by this volume of IEEE Std 1003.1-200x.

Issue 5
The description of tabs is clarified.
The FUTURE DIRECTIONS section is added.
Issue 6
The LEGACY items iuclc(-iuclc), xcase, olcuc(-olcuc), lcase(-lcase), and LCASE(-LCASE) are removed.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/37 is applied, applying IEEE PASC Interpretation 1003.2 \#133, fixing an error in the OPERANDS section for the Combination Modes $\mathrm{nl}(-\mathrm{nl})$.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

tabs - set terminal tabs

## SYNOPSIS

XSI tabs $[-n|-a|-a 2|-c|-c 2|-c 3|-f|-p|-s \mid-i]$ [+m[n]] [-T type]
tabs [-T type] [+[n]] n1[,n2,...]

## DESCRIPTION

The tabs utility shall display a series of characters that first clears the hardware terminal tab settings and then initializes the tab stops at the specified positions and optionally adjusts the margin.
The phrase "tab-stop position $N$ " shall be taken to mean that, from the start of a line of output, tabbing to position $N$ shall cause the next character output to be in the ( $N+1$ )th column position on that line. The maximum number of tab stops allowed is terminal-dependent.
It need not be possible to implement tabs on certain terminals. If the terminal type obtained from the TERM environment variable or -T option represents such a terminal, an appropriate diagnostic message shall be written to standard error and tabs shall exit with a status greater than zero.

## OPTIONS

The tabs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except for various extensions: the options -a2, $\mathbf{c} 2$, and -c 3 are multi-character.
The following options shall be supported:
-n Specify repetitive tab stops separated by a uniform number of column positions, $n$, where $n$ is a single-digit decimal number. The default usage of tabs with no arguments shall be equivalent to tabs -8 . When $-\mathbf{0}$ is used, the tab stops shall be cleared and no new ones set.

$$
1,10,16,36,72
$$

Assembler, applicable to some mainframes.

-a2 | Assembler, applicable to some mainframes. |
| :--- |

XSI

## 1,12,20,44

Assembler, applicable to some mainframes.
-T type Indicate the type of terminal. If this option is not supplied and the TERM variable is unset or null, an unspecified default terminal type shall be used. The setting of type shall take precedence over the value in TERM.

## OPERANDS

The following operand shall be supported:
$n 1[, n 2, \ldots]$ A single command line argument that consists of tab-stop values separated using either commas or <blank>s. The application shall ensure that the tab-stop values are positive decimal integers in strictly ascending order. If any number (except the first one) is preceded by a plus sign, it is taken as an increment to be added to the previous value. For example, the tab lists $1,10,20,30$ and $1,10,+10,+10$ are considered to be identical.

## STDIN

Not used.

## INPUT FILES

## None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of tabs:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TERM Determine the terminal type. If this variable is unset or null, and if the $-\mathbf{T}$ option is not specified, an unspecified default terminal type shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If standard output is a terminal, the appropriate sequence to clear and set the tab stops may be written to standard output in an unspecified format. If standard output is not a terminal, undefined results occur.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

This utility makes use of the terminal's hardware tabs and the stty tabs option.
This utility is not recommended for application use.
Some integrated display units might not have escape sequences to set tab stops, but may be set by internal system calls. On these terminals, tabs works if standard output is directed to the terminal; if output is directed to another file, however, tabs fails.

## EXAMPLES

None.

## RATIONALE

Consideration was given to having the tput utility handle all of the functions described in tabs. However, the separate tabs utility was retained because it seems more intuitive to use a command named tabs than tput with a new option. The tput utility does not support setting or clearing tabs, and no known historical version of tabs supports the capability of setting arbitrary tab stops.
The System V tabs interface is very complex; the version in this volume of IEEE Std 1003.1-200x has a reduced feature list, but many of the features omitted were restored as part of the XSI option even though the supported languages and coding styles are primarily historical.

There was considerable sentiment for specifying only a means of resetting the tabs back to a known state-presumably the "standard" of tabs every eight positions. The following features were omitted:

- Setting tab stops via the first line in a file, using --file. Since even the SVID has no complete explanation of this feature, it is doubtful that it is in widespread use.
In an early proposal, $\mathbf{a}-\mathbf{t}$ tablist option was added for consistency with expand; this was later removed when inconsistencies with the historical list of tabs were identified.

Consideration was given to adding $\mathbf{a}-\mathbf{p}$ option that would output the current tab settings so that they could be saved and then later restored. This was not accepted because querying the tab stops of the terminal is not a capability in historical terminfo or termcap facilities and might not be supported on a wide range of terminals.

## FUTURE DIRECTIONS

None.

expand, stty, tput, unexpand

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
The tabs utility is removed from the User Portability Utilities option. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
tail - copy the last part of a file

## SYNOPSIS

tail [-f] [-c number|-n number] [file]

## DESCRIPTION

The tail utility shall copy its input file to the standard output beginning at a designated place.
Copying shall begin at the point in the file indicated by the $-\mathbf{c}$ number or $-\mathbf{n}$ number options. The option-argument number shall be counted in units of lines or bytes, according to the options -n and $-\mathbf{c}$. Both line and byte counts start from 1.
Tails relative to the end of the file may be saved in an internal buffer, and thus may be limited in length. Such a buffer, if any, shall be no smaller than \{LINE_MAX\}*10 bytes.

## OPTIONS

The tail utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that ' + ' may be recognized as an option delimiter as well as '-'.

The following options shall be supported:
-c number The application shall ensure that the number option-argument is a decimal integer whose sign affects the location in the file, measured in bytes, to begin the copying:

| Sign | Copying Starts |
| :---: | :--- |
| + | Relative to the beginning of the file. |
| - | Relative to the end of the file. |
| none | Relative to the end of the file. |

The application shall ensure that if the sign of the number option-argument is ' + ', the number option-argument is a positive decimal integer.

The origin for counting shall be 1 ; that is, $-\mathbf{c}+1$ represents the first byte of the file, -c -1 the last.
-f If the input file is a regular file or if the file operand specifies a FIFO, do not terminate after the last line of the input file has been copied, but read and copy further bytes from the input file when they become available. If no file operand is specified and standard input is a pipe or FIFO, the $-\mathbf{f}$ option shall be ignored. If the input file is not a FIFO, pipe, or regular file, it is unspecified whether or not the -f option shall be ignored.
-n number This option shall be equivalent to - c number, except the starting location in the file shall be measured in lines instead of bytes. The origin for counting shall be 1 ; that is, $-\mathbf{n}+1$ represents the first line of the file, $-\mathbf{n}-1$ the last.
If neither $-\mathbf{c}$ nor $-\mathbf{n}$ is specified, $\mathbf{- n} 10$ shall be assumed.

## OPERANDS

The following operand shall be supported:
file A pathname of an input file. If no file operands are specified, the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

If the -c option is specified, the input file can contain arbitrary data; otherwise, the input file shall be a text file.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of tail:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The designated portion of the input file shall be written to standard output.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The -c option should be used with caution when the input is a text file containing multi-byte characters; it may produce output that does not start on a character boundary.

Although the input file to tail can be any type, the results might not be what would be expected on some character special device files or on file types not described by the System Interfaces volume of IEEE Std 1003.1-200x. Since this volume of IEEE Std 1003.1-200x does not specify the block size used when doing input, tail need not read all of the data from devices that only perform block transfers.

## EXAMPLES

The -f option can be used to monitor the growth of a file that is being written by some other process. For example, the command:

```
tail -f fred
```

prints the last ten lines of the file fred, followed by any lines that are appended to fred between the time tail is initiated and killed. As another example, the command:

```
tail -f -c 15 fred
```

prints the last 15 bytes of the file fred, followed by any bytes that are appended to fred between the time tail is initiated and killed.

## RATIONALE

This version of tail was created to allow conformance to the Utility Syntax Guidelines. The historical -b option was omitted because of the general non-portability of block-sized units of text. The -c option historically meant "characters", but this volume of IEEE Std 1003.1-200x indicates that it means "bytes". This was selected to allow reasonable implementations when multi-byte characters are possible; it was not named $-\mathbf{b}$ to avoid confusion with the historical -b .

The origin of counting both lines and bytes is 1 , matching all widespread historical implementations. Hence tail $-\mathbf{n}+0$ is not conforming usage because it attempts to output line zero; but note that tail -n 0 does conform, and outputs nothing.

Earlier versions of this standard allowed the following forms in the SYNOPSIS:
tail - [number][b|c|l][f] [file]
tail + [number][b|c|l][f][file]
These forms are no longer specified by this standard, but may be present in some implementations.
The restriction on the internal buffer is a compromise between the historical System V implementation of 4096 bytes and the BSD 32768 bytes.
The -f option has been implemented as a loop that sleeps for 1 second and copies any bytes that are available. This is sufficient, but if more efficient methods of determining when new data are available are developed, implementations are encouraged to use them.
Historical documentation indicates that tail ignores the $-\mathbf{f}$ option if the input file is a pipe (pipe and FIFO on systems that support FIFOs). On BSD-based systems, this has been true; on System V-based systems, this was true when input was taken from standard input, but it did not ignore the -f flag if a FIFO was named as the file operand. Since the -f option is not useful on pipes and all historical implementations ignore $-\mathbf{f}$ if no file operand is specified and standard input is a pipe, this volume of IEEE Std 1003.1-200x requires this behavior. However, since the $-\mathbf{f}$ option is useful on a FIFO, this volume of IEEE Std 1003.1-200x also requires that if a FIFO is named, the $-\mathbf{f}$ option shall not be ignored. Earlier versions of the standard did not state any requirement for the case where no file operand is specified and standard input is a FIFO. The standard has been updated to reflect current practice which is to treat this case the same as a pipe on standard
input. Although historical behavior does not ignore the -f option for other file types, this is unspecified so that implementations are allowed to ignore the $-\mathbf{f}$ option if it is known that the file cannot be extended.
This was changed to the current form based on comments noting that -c was almost never used without specifying a number and that there was no need to specify $\mathbf{- 1}$ if $\mathbf{- n}$ number was given.

## FUTURE DIRECTIONS

None.

head

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The obsolescent SYNOPSIS lines and associated text are removed.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying that ${ }^{\prime}+$ ' may be recognized as an option delimiter in the OPTIONS section.

Austin Group Interpretation 1003.1-2001 \#100 is applied, adding the requirement on applications that if the sign of the option-argument number is ' ${ }^{+\prime}$, the number option-argument is a positive decimal integer.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-114 is applied, updating the OPTIONS section (the $-\mathbf{f}$ option).

## NAME

talk - talk to another user

## SYNOPSIS

UP talk address [terminal]

## DESCRIPTION

The talk utility is a two-way, screen-oriented communication program.
When first invoked, talk shall send a message similar to:

```
Message from <unspecified string>
talk: connection requested by your_address
talk: respond with: talk your_address
```

to the specified address. At this point, the recipient of the message can reply by typing:
talk your_address
Once communication is established, the two parties can type simultaneously, with their output displayed in separate regions of the screen. Characters shall be processed as follows:

- Typing the alert character shall alert the recipient's terminal.
- Typing <control>-L shall cause the sender's screen regions to be refreshed.
- Typing the erase and kill characters shall affect the sender's terminal in the manner described by the termios interface in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
- Typing the interrupt or end-of-file characters shall terminate the local talk utility. Once the talk session has been terminated on one side, the other side of the talk session shall be notified that the talk session has been terminated and shall be able to do nothing except exit.
- Typing characters from LC_CTYPE classifications print or space shall cause those characters to be sent to the recipient's terminal.
- When and only when the stty iexten local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions shall be implementation-defined.
- Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be sent to the recipient's terminal.
Permission to be a recipient of a talk message can be denied or granted by use of the mesg utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The talk utility shall fail when the user lacks the appropriate privileges to perform the requested action.

Certain block-mode terminals do not have all the capabilities necessary to support the simultaneous exchange of messages required for talk. When this type of exchange cannot be supported on such terminals, the implementation may support an exchange with reduced levels of simultaneous interaction or it may report an error describing the terminal-related deficiency.

## OPTIONS

## OPERANDS

The following operands shall be supported:
address The recipient of the talk session. One form of address is the <user name>, as returned by the who utility. Other address formats and how they are handled are unspecified.
terminal If the recipient is logged in more than once, the terminal argument can be used to indicate the appropriate terminal name. If terminal is not specified, the talk message shall be displayed on one or more accessible terminals in use by the recipient. The format of terminal shall be the same as that returned by the who utility.

## STDIN

Characters read from standard input shall be copied to the recipient's terminal in an unspecified manner. If standard input is not a terminal, talk shall write a diagnostic message and exit with a non-zero status.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of talk:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient's locale does not use an LC_CTYPE equivalent to the sender's, the results are undefined.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xsI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TERM Determine the name of the invoker's terminal type. If this variable is unset or null, an unspecified default terminal type shall be used.

## ASYNCHRONOUS EVENTS

When the talk utility receives a SIGINT signal, the utility shall terminate and exit with a zero status. It shall take the standard action for all other signals.

## STDOUT

If standard output is a terminal, characters copied from the recipient's standard input may be written to standard output. Standard output also may be used for diagnostic messages. If standard output is not a terminal, talk shall exit with a non-zero status.

## STDERR

## OUTPUT FILES

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
>0 An error occurred or talk was invoked on a terminal incapable of supporting it.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Because the handling of non-printable, non-<space>s is tied to the stty description of iexten, implementation extensions within the terminal driver can be accessed. For example, some implementations provide line editing functions with certain control character sequences.

## EXAMPLES

None.

## RATIONALE

The write utility was included in this volume of IEEE Std 1003.1-200x since it can be implemented on all terminal types. The talk utility, which cannot be implemented on certain terminals, was considered to be a "better" communications interface. Both of these programs are in widespread use on historical implementations. Therefore, both utilities have been specified.
All references to networking abilities (talking to a user on another system) were removed as being outside the scope of this volume of IEEE Std 1003.1-200x.
Historical BSD and System V versions of talk terminate both of the conversations when either user breaks out of the session. This can lead to adverse consequences if a user unwittingly continues to enter text that is interpreted by the shell when the other terminates the session. Therefore, the version of talk specified by this volume of IEEE Std 1003.1-200x requires both users to terminate their end of the session explicitly.

Only messages sent to the terminal of the invoking user can be internationalized in any way:

- The original "Message from <unspecified string> ..." message sent to the terminal of the recipient cannot be internationalized because the environment of the recipient is as yet inaccessible to the talk utility. The environment of the invoking party is irrelevant.
- Subsequent communication between the two parties cannot be internationalized because the two parties may specify different languages in their environment (and non-portable characters cannot be mapped from one language to another).
- Neither party can be required to communicate in a language other than $C$ and/or the one specified by their environment because unavailable terminal hardware support (for example, fonts) may be required.

The text in the STDOUT section reflects the usage of the verb "display" in this section; some talk implementations actually use standard output to write to the terminal, but this volume of IEEE Std 1003.1-200x does not require that to be the case.
The format of the terminal name is unspecified, but the descriptions of $p s$, talk, who, and write require that they all use or accept the same format.

The handling of non-printable characters is partially implementation-defined because the details of mapping them to printable sequences is not needed by the user. Historical implementations, for security reasons, disallow the transmission of non-printable characters that may send commands to the other terminal.

## FUTURE DIRECTIONS

None.

mesg, stty, who, write, the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.

NAME
tee - duplicate standard input

## SYNOPSIS

tee [-ai] [file...]

## DESCRIPTION

The tee utility shall copy standard input to standard output, making a copy in zero or more files. The tee utility shall not buffer output.

If the -a option is not specified, output files shall be written (see Section 1.7.1.4 (on page 4).

## OPTIONS

The tee utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-a Append the output to the files.
-i Ignore the SIGINT signal.

## OPERANDS

The following operands shall be supported:
file A pathname of an output file. Processing of at least 13 file operands shall be supported.

## STDIN

The standard input can be of any type.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of tee:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default, except that if the -i option was specified, SIGINT shall be ignored.

## STDOUT

The standard output shall be a copy of the standard input.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

If any file operands are specified, the standard input shall be copied to each named file.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The standard input was successfully copied to all output files.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

If a write to any successfully opened file operand fails, writes to other successfully opened file operands and standard output shall continue, but the exit status shall be non-zero. Otherwise, the default actions specified in Section 1.11 apply.

## APPLICATION USAGE

The tee utility is usually used in a pipeline, to make a copy of the output of some utility.
The file operand is technically optional, but tee is no more useful than cat when none is specified.

## EXAMPLES

Save an unsorted intermediate form of the data in a pipeline:
... | tee unsorted | sort > sorted

## RATIONALE

The buffering requirement means that tee is not allowed to use ISO C standard fully buffered or line-buffered writes. It does not mean that tee has to do 1-byte reads followed by 1-byte writes.

It should be noted that early versions of BSD ignore any invalid options and accept a single ' -' as an alternative to -i. They also print a message if unable to open a file:
"tee: cannot access \%s \n", <pathname>
Historical implementations ignore write errors. This is explicitly not permitted by this volume of IEEE Std 1003.1-200x.

Some historical implementations use O_APPEND when providing append mode; others use the $l$ seek () function to seek to the end-of-file after opening the file without O_APPEND. This volume of IEEE Std 1003.1-200x requires functionality equivalent to using O_APPEND; see Section 1.7.1.4 (on page 4).

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.

IEEE PASC Interpretation 1003.2 \#168 is applied.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
test - evaluate expression

## SYNOPSIS

$$
\begin{aligned}
& \text { test [expression] } \\
& \text { [ [expression] ] }
\end{aligned}
$$

## DESCRIPTION

The test utility shall evaluate the expression and indicate the result of the evaluation by its exit status. An exit status of zero indicates that the expression evaluated as true and an exit status of 1 indicates that the expression evaluated as false.
In the second form of the utility, which uses " [] " rather than test, the application shall ensure that the square brackets are separate arguments.

## OPTIONS

The test utility shall not recognize the "--" argument in the manner specified by Guideline 10 in the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
No options shall be supported.

## OPERANDS

The application shall ensure that all operators and elements of primaries are presented as separate arguments to the test utility.
The following primaries can be used to construct expression:
-b pathname True if pathname resolves to a file that exists and is a block special file. False if pathname cannot be resolved, or if pathname resolves to a file that exists but is not a block special file.
-c pathname True if pathname resolves to a file that exists and is a character special file. False if pathname cannot be resolved, or if pathname resolves to a file that exists but is not a character special file.
-d pathname True if pathname resolves to a file that exists and is a directory. False if pathname cannot be resolved, or if pathname resolves to a file that exists but is not a directory.
-e pathname True if pathname resolves to a file that exists. False if pathname cannot be resolved.
-f pathname True if pathname resolves to a file that exists and is a regular file. False if pathname cannot be resolved, or if pathname resolves to a file that exists but is not a regular file.
-g pathname True if pathname resolves to a file that exists and has its set-group-ID flag set. False if pathname cannot be resolved, or if pathname resolves to a file that exists but does not have its set-group-ID flag set.
-h pathname True if pathname resolves to a file that exists and is a symbolic link. False if pathname cannot be resolved, or if pathname resolves to a file that exists but is not a symbolic link. If the final component of pathname is a symlink, that symlink is not followed.
-L pathname True if pathname resolves to a file that exists and is a symbolic link. False if pathname cannot be resolved, or if pathname resolves to a file that exists but is not a symbolic link. If the final component of pathname is a symlink, that symlink is not followed.

| 35935 | OB XSI | expression1-o expression 2 |
| :---: | :---: | :---: |
| 35936 |  | True if either expression1 or expression 2 is true; otherwise, false. The -o binary |
| 35937 |  | primary is left associative. |
| 938 |  | With the exception of the $\mathbf{- h}$ file and -L file primaries, if a file argument is a symbolic link, test shall evaluate the expression by resolving the symbolic link and using the file referenced by the link. |
| 35939 |  |  |
| 35940 |  |  |
| 35941 |  | These primaries can be combined with the following operators: |
| 35942 |  | ! expression True if expression is false. False if expression is true. |
| 35943 | OB XSI | (expression ) True if expression is true. False if expression is false. The parentheses can be used to |
| 35944 |  | alter the normal precedence and associativity. |
| 35945 |  | The primaries with two elements of the form: |
| 35946 |  | -primary_operator primary_operand |

are known as unary primaries. The primaries with three elements in either of the two forms:
primary_operand -primary_operator primary_operand
primary_operand primary_operator primary_operand
are known as binary primaries. Additional implementation-defined operators and primary_operators may be provided by implementations. They shall be of the form -operator where the first character of operator is not a digit.
The algorithm for determining the precedence of the operators and the return value that shall be generated is based on the number of arguments presented to test. (However, when using the " [ . . ] ] form, the right-bracket final argument shall not be counted in this algorithm.)
In the following list, $\$ 1, \$ 2, \$ 3$, and $\$ 4$ represent the arguments presented to test:
0 arguments: Exit false (1).
1 argument: Exit true (0) if $\$ 1$ is not null; otherwise, exit false.
2 arguments: - If $\$ 1$ is ' ! ', exit true if $\$ 2$ is null, false if $\$ 2$ is not null.

- If $\$ 1$ is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.
- If $\$ 2$ is a binary primary, perform the binary test of $\$ 1$ and $\$ 3$.
- If $\$ 1$ is ' !', negate the two-argument test of $\$ 2$ and $\$ 3$.
- If $\$ 1$ is ' (' and $\$ 3$ is ' $)^{\prime}$, perform the unary test of $\$ 2$. On systems that do not support the XSI option, the results are unspecified if $\$ 1$ is ' (' and $\$ 3$ is ') '
- Otherwise, produce unspecified results.

4 arguments: $\quad$ If $\$ 1$ is ' !' , negate the three-argument test of $\$ 2, \$ 3$, and $\$ 4$.

- If $\$ 1$ is ' (' and $\$ 4$ is ')', perform the two-argument test of $\$ 2$ and $\$ 3$. On systems that do not support the XSI option, the results are unspecified if $\$ 1$ is ' (' and $\$ 4$ is ') '.
- Otherwise, the results are unspecified.
$>4$ arguments: The results are unspecified.
ob xsI

STDIN
Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of test:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 expression evaluated to true.
1 expression evaluated to false or expression was missing.
>1 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The XSI extensions specifying the $-\mathbf{a}$ and -o binary primaries and the ' (' and ')' operators have been marked obsolescent. (Many expressions using them are ambiguously defined by the grammar depending on the specific expressions being evaluated.) Scripts using these expressions should be converted to the forms given below. Even though many implementations will continue to support these obsolescent forms, scripts should be extremely careful when dealing with user-supplied input that could be confused with these and other primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like:
test "\$1" -a "\$2"
should be written as:
test "\$1" \&\& test "\$2"
to avoid problems if a user supplied values such as $\$ 1$ set to ' !' and $\$ 2$ set to the null string. That is, in cases where maximal portability is of concern, replace:

```
test expr1 -a expr2
```

with:
test expr1 \&\& test expr2
and replace:
test expr1 -o expr2
with:
test expr1 || test expr2
but note that, in test, -a has higher precedence than -o while " $\& \&$ " and "||" have equal precedence in the shell.
Parentheses or braces can be used in the shell command language to effect grouping.
Parentheses must be escaped when using sh; for example:

```
test \( expr1 -a expr2 \) -o expr3
```

This command is not always portable even on XSI-conformant systems depending on the expressions specified by expr 1 , expr 2 , and expr 3 . The following form can be used instead:

```
( test expr1 && test expr2) /| test expr3
```

The two commands:
test "\$1"
test ! "\$1"
could not be used reliably on some historical systems. Unexpected results would occur if such a string expression were used and $\$ 1$ expanded to ' !', ' (', or a known unary primary. Better constructs are:
test -n "\$1"
test -z "\$1"
respectively.
Historical systems have also been unreliable given the common construct:
test "\$response" = "expected string"
One of the following is a more reliable form:

```
test "X$response" = "Xexpected string"
test "expected string" = "$response"
```

Note that the second form assumes that expected string could not be confused with any unary primary. If expected string starts with $\mathbf{I}^{\prime}, \prime^{\prime}\left(\prime, '!'\right.$, or even ${ }^{\prime}={ }^{\prime}$, the first form should be used instead. Using the preceding rules without the XSI marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted in all cases.)

Because the string comparison binary primaries, ${ }^{\prime}=$ ' and " $!="$, have a higher precedence than any unary primary in the greater than 4 argument case, unexpected results can occur if arguments are not properly prepared. For example, in:
test -d \$1 -o -d \$2
If $\$ 1$ evaluates to a possible directory name of $\quad=^{\prime}$, the first three arguments are considered a string comparison, which shall cause a syntax error when the second -d is encountered. One of the following forms prevents this; the second is preferred:

```
test \( -d "$1" \) -o \( -d "$2" \)
test -d "$1" || test -d "$2"
```

Also in the greater than 4 argument case:
test "\$1" = "bat" -a "\$2" = "ball"
syntax errors occur if $\$ 1$ evaluates to ' (' or ' ! ' . One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

## EXAMPLES

1. Exit if there are not two or three arguments (two variations):
```
if [ $# -ne 2 -a $# -ne 3]; then exit 1; fi
if [ $# -lt 2 -o $# -gt 3 ]; then exit 1; fi
```

2. Perform a mkdir if a directory does not exist:
```
test ! -d tempdir && mkdir tempdir
```

3. Wait for a file to become non-readable:
```
while test -r thefile
do
    sleep 30
done
echo '"thefile" is no longer readable'
```

4. Perform a command if the argument is one of three strings (two variations):
```
if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
then
    command
fi
case "$1" in
    pear|grape|apple) command ;;
esac
```

## RATIONALE

The KornShell-derived conditional command (double bracket [[ ]]) was removed from the shell command language description in an early proposal. Objections were raised that the real problem is misuse of the test command ([), and putting it into the shell is the wrong way to fix the problem. Instead, proper documentation and a new shell reserved word (!) are sufficient.

Tests that require multiple test operations can be done at the shell level using individual invocations of the test command and shell logicals, rather than using the error-prone -o flag of test.
XSI-conformant systems support more than four arguments.
XSI-conformant systems support the combining of primaries with the following constructs:
expression1-a expression2
True if both expression 1 and expression 2 are true.
expression1-o expression2
True if at least one of expression 1 and expression 2 are true.

## ( expression)

True if expression is true.
In evaluating these more complex combined expressions, the following precedence rules are used:

- The unary primaries have higher precedence than the algebraic binary primaries.
- The unary primaries have lower precedence than the string binary primaries.
- The unary and binary primaries have higher precedence than the unary string primary.
- The ! operator has higher precedence than the $-\mathbf{a}$ operator, and the $-\mathbf{a}$ operator has higher precedence than the -0 operator.
- The $-\mathbf{a}$ and $-\mathbf{o}$ operators are left associative.
- The parentheses can be used to alter the normal precedence and associativity.

The BSD and System V versions of $-f$ are not the same. The BSD definition was:
-f file True if file exists and is not a directory.
The SVID version (true if the file exists and is a regular file) was chosen for this volume of IEEE Std 1003.1-200x because its use is consistent with the $-\mathbf{b},-\mathbf{c},-\mathbf{d}$, and $-\mathbf{p}$ operands (file exists and is a specific file type).
The -e primary, possessing similar functionality to that provided by the $C$ shell, was added because it provides the only way for a shell script to find out if a file exists without trying to open the file. Since implementations are allowed to add additional file types, a portable script cannot use:
test -b foo -o -c foo -o -d foo -o -f foo -o -p foo
to find out if foo is an existing file. On historical BSD systems, the existence of a file could be determined by:
test -f foo -o -d foo
but there was no easy way to determine that an existing file was a regular file. An early proposal used the KornShell -a primary (with the same meaning), but this was changed to -e because there were concerns about the high probability of humans confusing the -a primary with the $\mathbf{- a}$ binary operator.
The following options were not included in this volume of IEEE Std 1003.1-200x, although they
are provided by some implementations. These operands should not be used by new implementations for other purposes:
-k file True if file exists and its sticky bit is set.
-C file $\quad$ True if file is a contiguous file.
-V file True if file is a version file.
The following option was not included because it was undocumented in most implementations, has been removed from some implementations (including System V), and the functionality is provided by the shell (see Section 2.6.2 (on page 38).
-1 string $\quad$ The length of the string string.
The $-\mathbf{b},-\mathbf{c},-\mathbf{g},-\mathbf{p},-\mathbf{u}$, and $-\mathbf{x}$ operands are derived from the SVID; historical BSD does not provide them. The $-\mathbf{k}$ operand is derived from System V; historical BSD does not provide it.
On historical BSD systems, test -w directory always returned false because test tried to open the directory for writing, which always fails.

Some additional primaries newly invented or from the KornShell appeared in an early proposal as part of the conditional command ([[]]): s1>s2,s1<s2,str = pattern, str $!=$ pattern, $f 1-\mathbf{n t} f 2, f 1$ -ot $f 2$, and $f 1$-ef $f 2$. They were not carried forward into the test utility when the conditional command was removed from the shell because they have not been included in the test utility built into historical implementations of the sh utility.

The $-\mathbf{t}$ file_descriptor primary is shown with a mandatory argument because the grammar is ambiguous if it can be omitted. Historical implementations have allowed it to be omitted, providing a default of 1 .

## FUTURE DIRECTIONS

None.

Section 1.7.1.4 (on page 4), find

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.

## Issue 6

The -h operand is added for symbolic links, and access permission requirements are clarified for the $-\mathbf{r},-\mathbf{w}$, and $-\mathbf{x}$ operands to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
The - $\mathbf{L}$ and -S operands are added for symbolic links and sockets.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/38 is applied, adding XSI margin marking and shading to a line in the OPERANDS section referring to the use of parentheses as arguments to the test utility.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/30 is applied, rewording the existence primaries for the test utility.

## Issue 7

Austin Group Interpretation 1003.1-2001 \#107 is applied.

NAME
time - time a simple command

## SYNOPSIS

```
time [-p] utility [argument...]
```

## DESCRIPTION

The time utility shall invoke the utility named by the utility operand with arguments supplied as the argument operands and write a message to standard error that lists timing statistics for the utility. The message shall include the following information:

- The elapsed (real) time between invocation of utility and its termination.
- The User CPU time, equivalent to the sum of the tms_utime and tms_cutime fields returned by the times () function defined in the System Interfaces volume of IEEE Std 1003.1-200x for the process in which utility is executed.
- The System CPU time, equivalent to the sum of the tms_stime and tms_cstime fields returned by the times () function for the process in which utility is executed.

The precision of the timing shall be no less than the granularity defined for the size of the clock tick unit on the system, but the results shall be reported in terms of standard time units (for example, 0.02 seconds, 00:00:00.02, $1 \mathrm{~m} 33.75 \mathrm{~s}, 365.21$ seconds), not numbers of clock ticks.
When time is used as part of a pipeline, the times reported are unspecified, except when it is the sole command within a grouping command (see Section 2.9.4.1 (on page 52)) in that pipeline. For example, the commands on the left are unspecified; those on the right report on utilities a and c , respectively:

```
time a | b < c { time a; \ b | c
a | b | time c a | b | (time c)
```

## OPTIONS

The time utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-p Write the timing output to standard error in the format shown in the STDERR section.

## OPERANDS

The following operands shall be supported:
utility The name of a utility that is to be invoked. If the utility operand names any of the special built-in utilities in Section 2.14 (on page 64), the results are undefined.
argument Any string to be supplied as an argument when invoking the utility named by the utility operand.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

## The following environment variables shall affect the execution of time:

LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic and informative messages written to standard error.

## LC_NUMERIC

Determine the locale for numeric formatting.
XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the search path that shall be used to locate the utility to be invoked; see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used to write the timing statistics. If $-\mathbf{p}$ is specified, the following format shall be used in the POSIX locale:

```
"real %f\nuser %f\nsys %f\n", <real seconds>, <user seconds>,
    <system seconds>
```

where each floating-point number shall be expressed in seconds. The precision used may be less than the default six digits of $\% f$, but shall be sufficiently precise to accommodate the size of the clock tick on the system (for example, if there were 60 clock ticks per second, at least two digits shall follow the radix character). The number of digits following the radix character shall be no less than one, even if this always results in a trailing zero. The implementation may append white space and additional information following the format shown here.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## None.

## EXIT STATUS

If the utility utility is invoked, the exit status of time shall be the exit status of utility; otherwise, the time utility shall exit with one of the following values:

1-125 An error occurred in the time utility.
126 The utility specified by utility was found but could not be invoked.

127 The utility specified by utility could not be found.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

## EXAMPLES

It is frequently desirable to apply time to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file, this file can then be invoked as a utility, and the time applies to everything in the file.

Alternatively, the following command can be used to apply time to a complex command:
time sh -c 'complex-command-line'

## RATIONALE

When the time utility was originally proposed to be included in the ISO POSIX-2: 1993 standard, questions were raised about its suitability for inclusion on the grounds that it was not useful for conforming applications, specifically:

- The underlying CPU definitions from the System Interfaces volume of IEEE Std 1003.1-200x are vague, so the numeric output could not be compared accurately between systems or even between invocations.
- The creation of portable benchmark programs was outside the scope this volume of IEEE Std 1003.1-200x.

However, time does fit in the scope of user portability. Human judgement can be applied to the analysis of the output, and it could be very useful in hands-on debugging of applications or in providing subjective measures of system performance. Hence it has been included in this volume of IEEE Std 1003.1-200x.
The default output format has been left unspecified because historical implementations differ greatly in their style of depicting this numeric output. The -p option was invented to provide scripts with a common means of obtaining this information.
In the KornShell, time is a shell reserved word that can be used to time an entire pipeline, rather than just a simple command. The POSIX definition has been worded to allow this implementation. Consideration was given to invalidating this approach because of the historical model from the C shell and System V shell. However, since the System V time utility historically has not produced accurate results in pipeline timing (because the constituent processes are not all owned by the same parent process, as allowed by POSIX), it did not seem worthwhile to break historical KornShell usage.
The term utility is used, rather than command, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, utility includes user application programs and shell scripts, not just the standard utilities.

## FUTURE DIRECTIONS

None.

## SEE ALSO

Chapter 2 (on page 29), sh, the System Interfaces volume of IEEE Std 1003.1-200x, times()

## CHANGE HISTORY

First released in Issue 2.
Issue 6
This utility is marked as part of the User Portability Utilities option.
Issue 7
The time utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-115 is applied, updating the example in the DESCRIPTION.

NAME
touch - change file access and modification times

## SYNOPSIS

```
touch [-acm] [-r ref_file|-t time] file...
```

## DESCRIPTION

The touch utility shall change the modification times, access times, or both of files. The modification time shall be equivalent to the value of the st_mtime member of the stat structure for a file, as described in the System Interfaces volume of IEEE Std 1003.1-200x; the access time shall be equivalent to the value of st_atime.
The time used can be specified by the -t time option-argument, the corresponding time fields of the file referenced by the -r ref_file option-argument, or the date_time operand, as specified in the following sections. If none of these are specified, touch shall use the current time (the value returned by the equivalent of the time() function defined in the System Interfaces volume of IEEE Std 1003.1-200x).

For each file operand, touch shall perform actions equivalent to the following functions defined in the System Interfaces volume of IEEE Std 1003.1-200x:

1. If file does not exist, a creat() function call is made with the file operand used as the path argument and the value of the bitwise-inclusive OR of S_IRUSR, S_IWUSR, S_IRGRP, S_IWGRP, S_IROTH, and S_IWOTH used as the mode argument.
2. The utime() function is called with the following arguments:
a. The file operand is used as the path argument.
b. The utimbuf structure members actime and modtime are determined as described in the OPTIONS section.

## OPTIONS

The touch utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a Change the access time of file. Do not change the modification time unless $\mathbf{- m}$ is also specified.
-c Do not create a specified file if it does not exist. Do not write any diagnostic messages concerning this condition.
$-\mathbf{m} \quad$ Change the modification time of file. Do not change the access time unless $-\mathbf{a}$ is also specified.
-r ref_file Use the corresponding time of the file named by the pathname ref_file instead of the current time.
$-\mathbf{t}$ time $\quad$ Use the specified time instead of the current time. The option-argument shall be a decimal number of the form:
[ [CC] YY] MMDDhhmm [.SS]
where each two digits represents the following:
$M M \quad$ The month of the year [01,12].

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TZ Determine the timezone to be used for interpreting the time option-argument. If TZ is unset or null, an unspecified default timezone shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The utility executed successfully and all requested changes were made.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The interpretation of time is taken to be seconds since the Epoch (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 4.14, Seconds Since the Epoch). It should be noted that implementations conforming to the System Interfaces volume of IEEE Std 1003.1-200x do not take leap seconds into account when computing seconds since the Epoch. When $S S=60$ is used, the resulting time always refers to 1 plus seconds since the Epoch for a time when $S S=59$.
Although the $-\mathbf{t}$ time option-argument specifies values in 1969, the access time and modification time fields are defined in terms of seconds since the Epoch (00:00:00 on 1 January 1970 UTC). Therefore, depending on the value of $T Z$ when touch is run, there is never more than a few valid hours in 1969 and there need not be any valid times in 1969.
One ambiguous situation occurs if $-\mathbf{t}$ time is not specified, $-\mathbf{r}$ ref_file is not specified, and the first operand is an eight or ten-digit decimal number. A portable script can avoid this problem by using:
touch -- file
or:
touch ./file
in this case.

## EXAMPLES

None.

## RATIONALE

The functionality of touch is described almost entirely through references to functions in the System Interfaces volume of IEEE Std 1003.1-200x. In this way, there is no duplication of effort required for describing such side effects as the relationship of user IDs to the user database, permissions, and so on.

There are some significant differences between the touch utility in this volume of IEEE Std 1003.1-200x and those in System V and BSD systems. They are upwards-compatible for historical applications from both implementations:

1. In System V, an ambiguity exists when a pathname that is a decimal number leads the operands; it is treated as a time value. In BSD, no time value is allowed; files may only be touched to the current time. The $-\mathbf{t}$ time construct solves these problems for future conforming applications (note that the $-\mathbf{t}$ option is not historical practice).
2. The inclusion of the century digits, $C C$, is also new. Note that a ten-digit time value is treated as if $Y Y$, and not $C C$, were specified. The caveat about the range of dates following the Epoch was included as recognition that some implementations are not able to represent dates beyond 18 January 2038 because they use signed int as a time holder.

The $-\mathbf{r}$ option was added because several comments requested this capability. This option was named -f in an early proposal, but was changed because the -f option is used in the BSD version of touch with a different meaning.

At least one historical implementation of touch incremented the exit code if -c was specified and the file did not exist. This volume of IEEE Std 1003.1-200x requires exit status zero if no errors occur.
In previous editions of the standard, if at least two operands are specified, and the first operand is an eight or ten-digit decimal integer, the first operand was assumed to be a date_time operand. This usage was removed in this edition of the standard since it had been marked obsolescent previously.

## FUTURE DIRECTIONS

Applications should use the $-\mathbf{r}$ or $-\mathbf{t}$ options.

## SEE ALSO

date, the System Interfaces volume of IEEE Std 1003.1-200x, creat (), time( ), utime (), the Base Definitions volume of IEEE Std 1003.1-200x, <sys/stat.h>

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The obsolescent date_time operand is removed.
The Open Group Corrigendum U027/1 is applied. This extends the range of valid time past the Epoch to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal Time. This is a new requirement on POSIX implementations.

The range for seconds is changed from [00,61] to [00,60] to align with the ISO/IEC 9899: 1999 standard, and to allow for positive leap seconds.

## Issue 7

SD5-XCU-ERN-45 is applied, adding a new paragraph to the RATIONALE.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-110 is applied, updating the OPTIONS section.

NAME
tput - change terminal characteristics

## SYNOPSIS

```
tput [-T type] operand...
```

## DESCRIPTION

The tput utility shall display terminal-dependent information. The manner in which this information is retrieved is unspecified. The information displayed shall clear the terminal screen, initialize the user's terminal, or reset the user's terminal, depending on the operand given. The exact consequences of displaying this information are unspecified.

## OPTIONS

The tput utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-T type Indicate the type of terminal. If this option is not supplied and the TERM variable is unset or null, an unspecified default terminal type shall be used. The setting of type shall take precedence oyer the value in TERM.

## OPERANDS

The following strings shall be supported as operands by the implementation in the POSIX locale:
clear Display the clear-screen sequence.
init Display the sequence that initializes the user's terminal in an implementationdefined manner.
reset Display the sequence that resets the user's terminal in an implementation-defined manner.

If a terminal does not support any of the operations described by these operands, this shall not be considered an error condition.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $t p u t$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
TERM Determine the terminal type. If this variable is unset or null, and if the $-\mathbf{T}$ option is not specified, an unspecified default terminal type shall be used.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

If standard output is a terminal device, it may be used for writing the appropriate sequence to clear the screen or reset or initialize the terminal. If standard output is not a terminal device, undefined results occur.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The requested string was written successfully.
1 Unspecified.
2 Usage error.
3 No information is available about the specified terminal type.
4 The specified operand is invalid.
>4 An error occurred.

## CONSEQUENCES OF ERRORS

If one of the operands is not available for the terminal, tput continues processing the remaining operands.

## APPLICATION USAGE

The difference between resetting and initializing a terminal is left unspecified, as they vary greatly based on hardware types. In general, resetting is a more severe action.
Some terminals use control characters to perform the stated functions, and on such terminals it might make sense to use tput to store the initialization strings in a file or environment variable for later use. However, because other terminals might rely on system calls to do this work, the standard output cannot be used in a portable manner, such as the following non-portable constructs:

ClearVar=`tput clear`
tput reset | mailx -s "Wake Up" ddg

## EXAMPLES

1. Initialize the terminal according to the type of terminal in the environmental variable $T E R M$. This command can be included in a .profile file.
tput init
2. Reset a 450 terminal.
```
tput -T 450 reset
```

## RATIONALE

The list of operands was reduced to a minimum for the following reasons:

- The only features chosen were those that were likely to be used by human users interacting with a terminal.
- Specifying the full terminfo set was not considered desirable, but the standard developers did not want to select among operands.
- This volume of IEEE Std 1003.1-200x does not attempt to provide applications with sophisticated terminal handling capabilities, as that falls outside of its assigned scope and intersects with the responsibilities of other standards bodies.
The difference between resetting and initializing a terminal is left unspecified as this varies greatly based on hardware types. In general, resetting is a more severe action.
The exit status of 1 is historically reserved for finding out if a Boolean operand is not set. Although the operands were reduced to a minimum, the exit status of 1 should still be reserved for the Boolean operands, for those sites that wish to support them.

## FUTURE DIRECTIONS

None.

> stty, tabs

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
Issue 7
The tput utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME
tr — translate characters

## SYNOPSIS

$$
\begin{aligned}
& \operatorname{tr}[-\mathrm{c} \mid-\mathrm{C}][-\mathrm{s}] \text { string1 string2 } \\
& \operatorname{tr}-\mathrm{s}[-\mathrm{c} \mid-\mathrm{C}] \text { string1 } \\
& \operatorname{tr}-\mathrm{d}[-\mathrm{c} \mid-\mathrm{C}] \text { string1 } \\
& \operatorname{tr}-\mathrm{ds}[-\mathrm{c} \mid-\mathrm{C}] \text { string1 string2 }
\end{aligned}
$$

## DESCRIPTION

The $t r$ utility shall copy the standard input to the standard output with substitution or deletion of selected characters. The options specified and the string1 and string2 operands shall control translations that occur while copying characters and single-character collating elements.

## OPTIONS

The $\operatorname{tr}$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

| -c | Complement the set of values specified by string1. See the EXTENDED <br> DESCRIPTION section. |
| :--- | :--- |
| $-\mathbf{C}$ | Complement the set of characters specified by string1. See the EXTENDED <br>  <br> DESCRIPTION section. |
| $-\mathbf{d}$ | Delete all occurrences of input characters that are specified by string1. |
| Replace instances of repeated characters with a single character, as described in the |  |
| EXTENDED DESCRIPTION section. |  |

## OPERANDS

The following operands shall be supported: string1, string2

Translation control strings. Each string shall represent a set of characters to be converted into an array of characters used for the translation. For a detailed description of how the strings are interpreted, see the EXTENDED DESCRIPTION section.

## STDIN

The standard input can be any type of file.

## INPUT FILES

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $t r$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

## LC_COLLATE

Determine the locale for the behavior of range expressions and equivalence classes.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments) and the behavior of character classes.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

The $t r$ output shall be identical to the input, with the exception of the specified transformations.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

The operands string1 and string2 (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, tr shall exclude, without a diagnostic, those multi-character elements from the resulting array.
character Any character not described by one of the conventions below shall represent itself.
loctal Octal sequences can be used to represent characters with specific coded values. An octal sequence shall consist of a backslash followed by the longest sequence of one, two, or three-octal-digit characters (01234567). The sequence shall cause the value whose encoding is represented by the one, two, or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading ' $\backslash$ ' for each byte.
\character The backslash-escape sequences in the Base Definitions volume of IEEE Std 1003.1-200x, Table 5-1, Escape Sequences and Associated Actions (' $\backslash \backslash$ ',

| 36691 | [:class:] | Represents all characters belonging to the defined character class, as defined by the |
| :---: | :---: | :---: |
| 36692 |  | current setting of the LC_CTYPE locale category. The following character class |
| 36693 |  | names shall be accepted when specified in string1: |
| 36694 |  | alnum blank digit lower punct upper |
| 36695 |  | alpha cntrl graph print space xdigit |
| 36696 |  | In addition, character class expressions of the form [:name:] shall be recognized in those locales where the name keyword has been given a charclass definition in the |
| 36697 |  |  |
| 36698 |  | LC_CTYPE category. |
| 36699 |  | When both the -d and -s options are specified, any of the character class names |
| 36700 |  | shall be accepted in string2. Otherwise, only character class names lower or upper |
| 36701 |  | are valid in string2 and then only if the corresponding character class (upper and |
| 36702 |  | lower, respectively) is specified in the same relative position in string1. Such a |
| 36703 |  | specification shall be interpreted as a request for case conversion. When [:lower:] |
| 36704 |  | appears in string1 and [:upper:] appears in string2, the arrays shall contain the |
| 36705 |  | characters from the toupper mapping in the LC_CTYPE category of the current |
| 36706 |  | locale. When [:upper:] appears in string1 and [:lower:] appears in string2, the arrays |
| 36707 |  | shall contain the characters from the tolower mapping in the LC_CTYPE category |
| 36708 |  | of the current locale. The first character from each mapping pair shall be in the |
| 36709 |  | array for string1 and the second character from each mapping pair shall be in the |
| 36710 |  | array for string2 in the same relative position. |
| 36711 |  | Except for case conversion, the characters specified by a character class expression |
| 36712 |  | shall be placed in the array in an unspecified order. |
| 36713 |  | If the name specified for class does not define a valid character class in the current |
| 36714 |  | locale, the behavior is undefined. |
| 36715 | [=equiv=] | Represents all characters or collating elements belonging to the same equivalence class as equiv, as defined by the current setting of the LC_COLLATE locale category. |
| 36716 |  |  |
| 36717 |  | An equivalence class expression shall be allowed only in string1, or in string2 when |
| 36718 |  | it is being used by the combined -d and -s options. The characters belonging to |
| 36719 |  | er equivalence class shall be placed in the array in an unspecified order. |
| 36720 | $\left[x^{*} n\right]$ <br> Represents $n$ repeated occurrences of the character $x$. Because this expression is used to map multiple characters to one, it is only valid when it occurs in string2. If $n$ is omitted or is zero, it shall be interpreted as large enough to extend the |  |
| 36721 |  |  |  |
| 36722 |  |  |  |
| 36723 |  | string2-based sequence to the length of the string1-based sequence. If $n$ has a |
| 36724 |  | leading zero, it shall be interpreted as an octal value. Otherwise, it shall be |
| 36725 |  |  |

When the -d option is not specified:

- Each input character found in the array specified by string1 shall be replaced by the character in the same relative position in the array specified by string2. When the array specified by string2 is shorter that the one specified by string1, the results are unspecified.
- If the -C option is specified, the complements of the characters specified by string1 (the set of all characters in the current character set, as defined by the current setting of LC_CTYPE, except for those actually specified in the string1 operand) shall be placed in the array in ascending collation sequence, as defined by the current setting of LC_COLLATE.
- If the -c option is specified, the complement of the values specified by string1 shall be placed in the array in ascending order by binary value.
- Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described
previously.
When the -d option is specified:
- Input characters found in the array specified by string1 shall be deleted.
- When the -C option is specified with -d, all characters except those specified by string1 shall be deleted. The contents of string2 are ignored, unless the -s option is also specified.
- When the -c option is specified with -d, all values except those specified by string1 shall be deleted. The contents of string2 shall be ignored, unless the - s option is also specified.
- The same string cannot be used for both the -d and the -s option; when both options are specified, both string1 (used for deletion) and string2 (used for squeezing) shall be required.
When the -s option is specified, after any deletions or translations have taken place, repeated sequences of the same character shall be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:
tr -s '[:space:]'
the last operand's array shall contain all of the characters in that character class. However, in a case conversion, as described previously, such as:
tr -s '[:upper:]' '[:lower:]'
the last operand's array shall contain only those characters defined as the second characters in each of the toupper or tolower character pairs, as appropriate.
An empty string used for string1 or string2 produces undefined results.

## EXIT STATUS

The following exit values shall be returned:
0 All input was processed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

If necessary, string1 and string2 can be quoted to avoid pattern matching by the shell.
If an ordinary digit (representing itself) is to follow an octal sequence, the octal sequence must use the full three digits to avoid ambiguity.
When string2 is shorter than string1, a difference results between historical System V and BSD systems. A BSD system pads string2 with the last character found in string2. Thus, it is possible to do the following:
tr 0123456789 d
which would translate all digits to the letter ${ }^{\prime} d^{\prime}$. Since this area is specifically unspecified in this volume of IEEE Std 1003.1-200x, both the BSD and System V behaviors are allowed, but a conforming application cannot rely on the BSD behavior. It would have to code the example in the following way:
tr 0123456789 ' [d*]'
It should be noted that, despite similarities in appearance, the string operands used by $t r$ are not regular expressions.
Unlike some historical implementations, this definition of the $t r$ utility correctly processes NUL
characters in its input stream. NUL characters can be stripped by using:

$$
\mathrm{tr}-\mathrm{d} \times \backslash 000^{\prime}
$$

## EXAMPLES

1. The following example creates a list of all words in file1 one per line in file2, where a word is taken to be a maximal string of letters.
tr -cs "[:alpha:]" "[\n*]" <file1 >file2
2. The next example translates all lowercase characters in file1 to uppercase and writes the results to standard output.
tr "[:lower:]" "[:upper:]" <file1
3. This example uses an equivalence class to identify accented variants of the base character ' $e^{\prime}$ in file1, which are stripped of diacritical marks and written to file2.
tr " [=e=]" "[e*]" <file1 >file2

## RATIONALE

In some early proposals, an explicit option -n was added to disable the historical behavior of stripping NUL characters from the input. It was considered that automatically stripping NUL characters from the input was not correct functionality. However, the removal of $\mathbf{- n}$ in a later proposal does not remove the requirement that $t r$ correctly process NUL characters in its input stream. NUL characters can be stripped by using $\operatorname{tr}-\mathbf{d}$ ' $\backslash 000$ '
Historical implementations of $t r$ differ widely in syntax and behavior. For example, the BSD version has not needed the bracket characters for the repetition sequence. The $t r$ utility syntax is based more closely on the System V and XPG3 model while attempting to accommodate historical BSD implementations. In the case of the short string2 padding, the decision was to unspecify the behavior and preserve System V and XPG3 scripts, which might find difficulty with the BSD method. The assumption was made that BSD users of $t r$ have to make accommodations to meet the syntax defined here. Since it is possible to use the repetition sequence to duplicate the desired behavior, whereas there is no simple way to achieve the System V method, this was the correct, if not desirable, approach.

The use of octal values to specify control characters, while having historical precedents, is not portable. The introduction of escape sequences for control characters should provide the necessary portability. It is recognized that this may cause some historical scripts to break.

An early proposal included support for multi-character collating elements. It was pointed out that, while $t r$ does employ some syntactical elements from REs, the aim of $t r$ is quite different; ranges, for example, do not have a similar meaning ("any of the chars in the range matches", versus "translate each character in the range to the output counterpart"). As a result, the previously included support for multi-character collating elements has been removed. What remains are ranges in current collation order (to support, for example, accented characters), character classes, and equivalence classes.

In XPG3 the [:class:] and [=equiv=] conventions are shown with double brackets, as in RE syntax. However, $t r$ does not implement RE principles; it just borrows part of the syntax. Consequently, [:class:] and [=equiv=] should be regarded as syntactical elements on a par with [ $x^{*} n$ ], which is not an RE bracket expression.
The standard developers will consider changes to $t r$ that allow it to translate characters between different character encodings, or they will consider providing a new utility to accomplish this.

On historical System V systems, a range expression requires enclosing square-brackets, such as:
tr ' [a-z]' ' [A-Z]'
However, BSD-based systems did not require the brackets, and this convention is used here to
avoid breaking large numbers of BSD scripts:
tr a-z A-Z
The preceding System V script will continue to work because the brackets, treated as regular characters, are translated to themselves. However, any System V script that relied on "a-z" representing the three characters ' $a^{\prime},{ }^{\prime}-$ ', and ${ }^{\prime} z^{\prime}$ have to be rewritten as "az-".

The ISO POSIX-2: 1993 standard had a -c option that behaved similarly to the - C option, but did not supply functionality equivalent to the -c option specified in IEEE Std 1003.1-200x. This meant that historical practice of being able to specify $\operatorname{tr}-\mathbf{c d} \backslash 000-\backslash 177$ (which would delete all bytes with the top bit set) would have no effect because, in the $C$ locale, bytes with the values octal 200 to octal 377 are not characters.

The earlier version also said that octal sequences referred to collating elements and could be placed adjacent to each other to specify multi-byte characters. However, it was noted that this caused ambiguities because $t r$ would not be able to tell whether adjacent octal sequences were intending to specify multi-byte characters or multiple single byte characters. IEEE Std 1003.1-200x specifies that octal sequences always refer to single byte binary values when used to specify an endpoint of a range of collating elements.

Previous versions of this standard allowed for implementations with bytes other than eight bits, but this has been modified in this version.

## FUTURE DIRECTIONS

None.

## SEE ALSO

sed

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The $-\mathbf{C}$ operand is added, and the description of the -c operand is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/31 is applied, removing text describing behavior on systems with bytes consisting of more than eight bits.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/32 is applied, updating an example in the EXAMPLES section to avoid using unspecified behavior.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/33 is applied, making a correction to the RATIONALE.

Issue 7
SD5-XCU-ERN-30 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
true - return true value
SYNOPSIS
true
DESCRIPTION
The true utility shall return with exit code zero.

## OPTIONS

None.
OPERANDS
None.

## STDIN

Not used.
INPUT FILES
None.
ENVIRONMENT VARIABLES
None.
ASYNCHRONOUS EVENTS
Default.
STDOUT
Not used.

## STDERR

Not used.
OUTPUT FILES
None.
EXTENDED DESCRIPTION
None.
EXIT STATUS
Zero.
CONSEQUENCES OF ERRORS
None.
APPLICATION USAGE
This utility is typically used in shell scripts, as shown in the EXAMPLES section. The special built-in utility : is sometimes more efficient than true.

EXAMPLES
This command is executed forever:
while true
do

```
        command
```

done

## RATIONALE

The true utility has been retained in this volume of IEEE Std 1003.1-200x, even though the shell special built-in : provides similar functionality, because true is widely used in historical scripts and is less cryptic to novice script readers.

## FUTURE DIRECTIONS

None.
SEE ALSO
false, Section 2.9

## CHANGE HISTORY

First released in Issue 2.
Issue 6
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/39 is applied, replacing the terms "None" and "Default" from the STDERR and EXIT STATUS sections, respectively, with terms as defined in Section 1.11 (on page 18).

NAME
tsort - topological sort

## SYNOPSIS

```
tsort [file]
```

## DESCRIPTION

The tsort utility shall write to standard output a totally ordered list of items consistent with a partial ordering of items contained in the input.

The application shall ensure that the input consists of pairs of items (non-empty strings) separated by <blank>s. Pairs of different items indicate ordering. Pairs of identical items indicate presence, but not ordering.

## OPTIONS

None.

## OPERANDS

The following operand shall be supported:
file A pathname of a text file to order. If no file operand is given, the standard input shall be used.

## STDIN

The standard input shall be a text file that is used if no file operand is given.

## INPUT FILES

The input file named by the file operand is a text file.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of tsort:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be a text file consisting of the order list produced from the partially ordered input.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.
EXTENDED DESCRIPTION
None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The LC_COLLATE variable need not affect the actions of tsort. The output ordering is not lexicographic, but depends on the pairs of items given as input.

## EXAMPLES

The command:
tsort < $<$ EOF
a b c c de
g $g$
f g ef
h h
EOF
produces the output:
a
b
C
d
e
f
g
h

## RATIONALE

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.

NAME
tty - return user's terminal name

## SYNOPSIS

## tty

## DESCRIPTION

The tty utility shall write to the standard output the name of the terminal that is open as standard input. The name that is used shall be equivalent to the string that would be returned by the ttyname () function defined in the System Interfaces volume of IEEE Std 1003.1-200x.

## OPTIONS

The $t t y$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

## OPERANDS

None.

## STDIN

While no input is read from standard input, standard input shall be examined to determine whether or not it is a terminal, and, if so, to determine the name of the terminal.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of tty:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

If standard input is a terminal device, a pathname of the terminal as specified by the ttyname () function defined in the System Interfaces volume of IEEE Std 1003.1-200x shall be written in the following format:
"\%s\n", <terminal name>
Otherwise, a message shall be written indicating that standard input is not connected to a terminal. In the POSIX locale, the tty utility shall use the format:

```
"not a tty\n"
```

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Standard input is a terminal.
1 Standard input is not a terminal.
$>1$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

This utility checks the status of the file open as standard input against that of an implementation-defined set of files. It is possible that no match can be found, or that the match found need not be the same file as that which was opened for standard input (although they are the same device).

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The SYNOPSIS is changed to indicate two forms of the command, with the second form marked as obsolete. This is a clarification and does not change the functionality published in previous issues.

Issue 6
The obsolescent-s option is removed.

NAME
type - write a description of command type

## SYNOPSIS

xSI type name...

## DESCRIPTION

The type utility shall indicate how each argument would be interpreted if used as a command name.

## OPTIONS

None.
OPERANDS
The following operand shall be supported:
name A name to be interpreted.
STDIN
Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of type:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH Determine the location of name, as described in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 8, Environment Variables.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output of type contains information about each operand in an unspecified format. The information provided typically identifies the operand as a shell built-in, function, alias, or keyword, and where applicable, may display the operand's pathname.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.
EXTENDED DESCRIPTION
None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Since type must be aware of the contents of the current shell execution environment (such as the lists of commands, functions, and built-ins processed by hash), it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:
nohup type writer
find . -type f | xargs type
it might not produce accurate results.

## EXAMPLES

None.

command, hash

## CHANGE HISTORY

First released in Issue 2.

NAME
ulimit - set or report file size limit

## SYNOPSIS

xSI ulimit [-f] [blocks]

## DESCRIPTION

The ulimit utility shall set or report the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.

## OPTIONS

The ulimit utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
$-\mathbf{f} \quad$ Set (or report, if no blocks operand is present), the file size limit in blocks. The -f option shall also be the default case.

## OPERANDS

The following operand shall be supported:
blocks The number of 512-byte blocks to use as the new file size limit.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of ulimit:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be used when no blocks operand is present. If the current number of blocks is limited, the number of blocks in the current limit shall be written in the following format:

```
"%d\n", <number of 512-byte blocks>
```

If there is no current limit on the number of blocks, in the POSIX locale the following format shall be used:
"unlimited\n"
STDERR
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ A request for a higher limit was rejected or an error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Since ulimit affects the current shell execution environment, it is always provided as a shell regular built-in. If it is called in a separate utility execution environment, such as one of the following:
nohup ulimit -f 10000
env ulimit 10000
it does not affect the file size limit of the caller's environment.
Once a limit has been decreased by a process, it cannot be increased (unless appropriate privileges are involved), even back to the original system limit.

## EXAMPLES

Set the file size limit to 51200 bytes:
ulimit -f 100

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
umask - get or set the file mode creation mask

## SYNOPSIS

```
umask [-S] [mask]
```

## DESCRIPTION

The umask utility shall set the file mode creation mask of the current shell execution environment (see Section 2.12 (on page 61)) to the value specified by the mask operand. This mask shall affect the initial value of the file permission bits of subsequently created files. If umask is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . -exec umask ... \;
```

it shall not affect the file mode creation mask of the caller's environment.
If the mask operand is not specified, the umask utility shall write to standard output the value of the file mode creation mask of the invoking process.

## OPTIONS

The umask utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-S Produce symbolic output.
The default output style is unspecified, but shall be recognized on a subsequent invocation of umask on the same system as a mask operand to restore the previous file mode creation mask.

## OPERANDS

The following operand shall be supported:
mask A string specifying the new file mode creation mask. The string is treated in the same way as the mode operand described in the EXTENDED DESCRIPTION section for chmod.

For a symbolic_mode value, the new value of the file mode creation mask shall be the logical complement of the file permission bits portion of the file mode specified by the symbolic_mode string.
In a symbolic_mode value, the permissions op characters '+' and ' -' shall be interpreted relative to the current file mode creation mask; ' + ' shall cause the bits for the indicated permissions to be cleared in the mask; ' ${ }^{\prime}$ ' shall cause the bits for the indicated permissions to be set in the mask.
The interpretation of mode values that specify file mode bits other than the file permission bits is unspecified.

In the octal integer form of mode, the specified bits are set in the file mode creation mask.

The file mode creation mask shall be set to the resulting numeric value.
The default output of a prior invocation of umask on the same system with no operand also shall be recognized as a mask operand.

## umask

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of umask:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

When the mask operand is not specified, the umask utility shall write a message to standard output that can later be used as a umask mask operand.
If $-\mathbf{S}$ is specified, the message shall be in the following format:

```
"u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>,
    <other permissions>
```

where the three values shall be combinations of letters from the set $\{r, w, x\}$; the presence of a letter shall indicate that the corrt of letTJ- shal Tdia4orr2OcRH of, of a

## CONSEQUENCES OF ERRORS

## APPLICATION USAGE

Since umask affects the current shell execution environment, it is generally provided as a shell regular built-in.

In contrast to the negative permission logic provided by the file mode creation mask and the octal number form of the mask argument, the symbolic form of the mask argument specifies those permissions that are left alone.

## EXAMPLES

Either of the commands:

```
umask a=rx,ug+w
```

umask 002
sets the mode mask so that subsequently created files have their S_IWOTH bit cleared.
After setting the mode mask with either of the above commands, the umask command can be used to write out the current value of the mode mask:
\$ umask
0002
(The output format is unspecified, but historical implementations use the octal integer mode format.)
\$ umask -S
$u=r w x, g=r w x, o=r x$
Either of these outputs can be used as the mask operand to a subsequent invocation of the umask utility.
$37333373343 \mathrm{~cm} \mathrm{BT} / \mathrm{R1} 18$ TAssbraniingsthesmodemmask is set as above, the command:

```
umask g-w
```

sets the mode mask so that subsequently created files have their S_IWGRP and S_IWOTH bits cleared.

The command:
umask -- -w
sets the mode mask so that subsequently created files have all their write bits cleared. Note that mask operands $-\mathbf{r},-\mathbf{w},-\mathbf{x}$ or anything beginning with a hyphen, must be preceded by "--" to keep it from being interpreted as an option.

## RATIONALE

Since umask affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(umask 002)
nohup umask ...
find . -exec umask ... \;
```

it does not affect the file mode creation mask of the environment of the caller.
The description of the historical utility was modified to allow it to use the symbolic modes of chmod. The -s option used in early proposals was changed to -S because -s could be confused with a symbolic_mode form of mask referring to the S_ISUID and S_ISGID bits.
The default output style is unspecified to permit implementors to provide migration to the new
symbolic style at the time most appropriate to their users. A -o flag to force octal mode output was omitted because the octal mode may not be sufficient to specify all of the information that may be present in the file mode creation mask when more secure file access permission checks are implemented.
It has been suggested that trusted systems developers might appreciate ameliorating the requirement that the mode mask "affects" the file access permissions, since it seems access control lists might replace the mode mask to some degree. The wording has been changed to say that it affects the file permission bits, and it leaves the details of the behavior of how they affect the file access permissions to the description in the System Interfaces volume of IEEE Std 1003.1-200x.

## FUTURE DIRECTIONS

None.

## SEE ALSO

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The octal mode is supported.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/34 is applied, making a correction to the RATIONALE.

## Issue 7

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME unalias - remove alias definitions

## SYNOPSIS

unalias alias-name...
unalias -a
DESCRIPTION
The unalias utility shall remove the definition for each alias name specified. See Section 2.3.1 (on page 32). The aliases shall be removed from the current shell execution environment; see Section 2.12 (on page 61).

## OPTIONS

The unalias utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported:
-a Remove all alias definitions from the current shell execution environment.

## OPERANDS

The following operand shall be supported:
alias-name The name of an alias to be removed.

## STDIN

Not used.
INPUT FILES
None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of unalias:
$L A N G \quad$ Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
XSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ One of the alias-name operands specified did not represent a valid alias definition, or an error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Since unalias affects the current shell execution environment, it is generally provided as a shell regular built-in.

## EXAMPLES

None.

## RATIONALE

The unalias description is based on that from historical KornShell implementations. Known differences exist between that and the C shell. The KornShell version was adopted to be consistent with all the other KornShell features in this volume of IEEE Std 1003.1-200x, such as command line editing.
The $-\mathbf{a}$ option is the equivalent of the unalias * form of the $C$ shell and is provided to address security concerns about unknown aliases entering the environment of a user (or application) through the allowable implementation-defined predefined alias route or as a result of an ENV file. (Although unalias could be used to simplify the "secure" shell script shown in the command rationale, it does not obviate the need to quote all command names. An initial call to unalias $\mathbf{- a}$ would have to be quoted in case there was an alias for unalias.)

## FUTURE DIRECTIONS

None.

## SEE ALSO

Chapter 2 (on page 29), alias

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
Issue 7
The unalias utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

NAME
uname - return system name

## SYNOPSIS

```
uname [-snrvma]
```

## DESCRIPTION

By default, the uname utility shall write the operating system name to standard output. When options are specified, symbols representing one or more system characteristics shall be written to the standard output. The format and contents of the symbols are implementation-defined. On systems conforming to the System Interfaces volume of IEEE Std 1003.1-200x, the symbols written shall be those supported by the uname() function as defined in the System Interfaces volume of IEEE Std 1003.1-200x.

## OPTIONS

The uname utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-a Behave as though all of the options -mnrsv were specified.
$-\mathbf{m} \quad$ Write the name of the hardware type on which the system is running to standard output.
-n Write the name of this node within an implementation-defined communications network.
-r Write the current release level of the operating system implementation.
-s Write the name of the implementation of the operating system.
-v Write the current version level of this release of the operating system implementation.

If no options are specified, the uname utility shall write the operating system name, as if the -s option had been specified.

## OPERANDS

None.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of uname:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

## uname

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

By default, the output shall be a single line of the following form:
"\%s\n", <sysname>
If the -a option is specified, the output shall be a single line of the following form:

```
"\%s \%s \%s \%s \%s s ", <sysname>, <nodename>, <release>,
```

        <version>, <machine>
    Additional implementation-defined symbols may be written; all such symbols shall be written at the end of the line of output before the <newline>.

If options are specified to select different combinations of the symbols, only those symbols shall be written, in the order shown above for the -a option. If a symbol is not selected for writing, its corresponding trailing <blank>s also shall not be written.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The requested information was successfully written.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

Note that any of the symbols could include embedded <space>s, which may affect parsing algorithms if multiple options are selected for output.
The node name is typically a name that the system uses to identify itself for inter-system communication addressing.

## EXAMPLES

The following command:

```
uname -sr
```

writes the operating system name and release level, separated by one or more <blank>s.

## RATIONALE

It was suggested that this utility cannot be used portably since the format of the symbols is implementation-defined. The POSIX. 1 working group could not achieve consensus on defining these formats in the underlying uname() function, and there was no expectation that this volume of IEEE Std 1003.1-200x would be any more successful. Some applications may still find this historical utility of value. For example, the symbols could be used for system log entries or for
comparison with operator or user input.
FUTURE DIRECTIONS
None.

CHANGE HISTORY
First released in Issue 2.

## NAME

 uncompress - expand compressed data
## SYNOPSIS

xSI uncompress [-cfv] [file...]

DESCRIPTION
The uncompress utility shall restor

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

When there are no file operands or the -c option is specified, the uncompressed output is written to standard output.

## STDERR

Prompts shall be written to the standard error output under the conditions specified in the DESCRIPTION and OPTIONS sections. The prompts shall contain the file pathname, but their format is otherwise unspecified. Otherwise, the standard error output shall be used only for diagnostic messages.

## OUTPUT FILES

Output files are the same as the respective input files to compress.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

The input file remains unmodified.

## APPLICATION USAGE

The limit of 14 on the compress - $\mathbf{b}$ bits argument is to achieve portability to all systems (within the restrictions imposed by the lack of an explicit published file format). Some implementations based on 16-bit architectures cannot support 15 or 16-bit uncompression.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.
SEE ALSO
compress, zcat

## CHANGE HISTORY

First released in Issue 4.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
SD5-XCU-ERN-26 is applied, clarifying that this utility is allowed to break the Utility Syntax Guidelines by having ten letters in its name.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
unexpand - convert spaces to tabs

## SYNOPSIS

```
unexpand [-a|-t tablist] [file...]
```

## DESCRIPTION

The unexpand utility shall copy files or standard input to standard output, converting <blank>s at the beginning of each line into the maximum number of <tab>s followed by the minimum number of <space>s needed to fill the same column positions originally filled by the translated <blank>s. By default, tabstops shall be set at every eighth column position. Each <backspace> shall be copied to the output, and shall cause the column position count for tab calculations to be decremented; the count shall never be decremented to a value less than one.

## OPTIONS

The unexpand utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following options shall be supported:
-a In addition to translating <blank>s at the beginning of each line, translate all sequences of two or more <blank>s immediately preceding a tab stop to the maximum number of <tab>s followed by the minimum number of <space>s needed to fill the same column positions originally filled by the translated <blank>s.
-t tablist Specify the tab stops. The application shall ensure that the tablist option-argument is a single argument consisting of a single positive decimal integer or multiple posítive decimal integers, separated by <blank>s or commas, in ascending order. If a single number is given, tabs shall be set tablist column positions apart instead of the default 8. If multiple numbers are given, the tabs shall be set at those specific column positions.

The application shall ensure that each tab-stop position $N$ is an integer value greater than zero, and the list shall be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position $N$ shall cause the next character output to be in the $(N+1)$ th column position on that line. When the $-\mathbf{t}$ option is not specified, the default shall be the equivalent of specifying $-\mathbf{t} \mathbf{8}$ (except for the interaction with-a, described below).
No <space>-to-<tab> conversions shall occur for characters at positions beyond the last of those specified in a multiple tab-stop list.
When $-\mathbf{t}$ is specified, the presence or absence of the $-\mathbf{a}$ option shall be ignored; conversion shall not be limited to the processing of leading <blank>s.

## OPERANDS

The following operand shall be supported:
file A pathname of a text file to be used as input.

## STDIN

See the INPUT FILES section.

## INPUT FILES

The input files shall be text files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of unexpand:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files), the processing of <tab>s and <space>s, and for the determination of the width in column positions each character would occupy on an output device.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be equivalent to the input files with the specified <space>-to-<tab> conversions.

## STDERR

The standard error shall be used only for diagnostic messages.
OUTPUT FILES
None.

## EXTENDED DESCRIPTION

None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

One non-intuitive aspect of unexpand is its restriction to leading spaces when neither $-\mathbf{a}$ nor $-\mathbf{t}$ is specified. Users who always want to convert all spaces in a file can easily alias unexpand to use the $-\mathbf{a}$ or $-\mathbf{t} 8$ option.

## EXAMPLES

None.

## RATIONALE

On several occasions, consideration was given to adding a $\mathbf{- t}$ option to the unexpand utility to complement the $-\mathbf{t}$ in expand (see expand). The historical intent of unexpand was to translate multiple <blank>s into tab stops, where tab stops were a multiple of eight column positions on most UNIX systems. An early proposal omitted -t because it seemed outside the scope of the User Portability Utilities option; it was not described in any of the base documents. However, hard-coding tab stops every eight columns was not suitable for the international community and broke historical precedents for some vendors in the FORTRAN community, so -t was restored in conjunction with the list of valid extension categories considered by the standard developers. Thus, unexpand is now the logical converse of expand.

## FUTURE DIRECTIONS

None.

## SEE ALSO

expand, tabs

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The definition of the LC_CTYPE environment variable is changed to align with the IEEE P1003.2b draft standard.

The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
The unexpand utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
unget - undo a previous get of an SCCS file (DEVELOPMENT)

## SYNOPSIS

xSI unget [-ns] [-r SID] file...

## DESCRIPTION

The unget utility shall reverse the effect of a get -e done prior to creating the intended new delta.

## OPTIONS

The unget utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section
12.2, Utility Syntax Guidelines.

The following options shall be supported:
-r SID Uniquely identify which delta is no longer intended. (This would have been specified by get as the new delta.) The use of this option is necessary only if two or more outstanding get commands for editing on the same SCCS file were done by the same person (login name).
-s Suppress the writing to standard output of the intended delta's SID.
-n Retain the file that was obtained by get, which would normally be removed from the current directory.

## OPERANDS

The following operands shall be supported:
file A pathname of an existing SCCS file or a directory. If file is a directory, the unget utility shall behave as though each file in the directory were specified as a named file, except that non-SCCS files (last component of the pathname does not begin with s.) and unreadable files shall be silently ignored.

If exactly one file operand appears, and it is ${ }^{\prime}-^{\prime}$, the standard input shall be read; each line of the standard input shall be taken to be the name of an SCCS file to be processed. Non-SCCS files and unreadable files shall be silently ignored.

## STDIN

The standard input shall be a text file used only when the file operand is specified as ${ }^{\prime} \mathbf{~}^{\prime}$. Each line of the text file shall be interpreted as an SCCS pathname.

## INPUT FILES

Any SCCS files processed shall be files of an unspecified format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of unget:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall consist of a line for each file, in the following format:
"\%s\n", <SID removed from file>
If there is more than one named file or if a directory or standard input is named, each pathname shall be written before each of the preceding lines:
" $\backslash \mathrm{n} \% \mathrm{~s}: \backslash \mathrm{n} ", ~<p a t h n a m e>$

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

Any SCCS files updated shall be files of an unspecified format. During processing of a file, a locking $z$-file, as described in get, and a $q$-file (a working copy of the $p$-file), may be created and deleted. The $p$-file and $g$-file, as described in get, shall be deleted.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.

NAME
uniq - report or filter out repeated lines in a file

## SYNOPSIS

uniq [-c|-d|-u] [-f fields] [-s char] [input_file [output_file]]

## DESCRIPTION

The uniq utility shall read an input file comparing adjacent lines, and write one copy of each input line on the output. The second and succeeding copies of repeated adjacent input lines shall not be written.
Repeated lines in the input shall not be detected if they are not adjacent.

## OPTIONS

The uniq utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that ' + ' may be recognized as an option delimiter as well as '-'.

The following options shall be supported:
-c Precede each output line with a count of the number of times the line occurred in the input.
-d Suppress the writing of lines that are not repeated in the input.
-f fields Ignore the first fields fields on each input line when doing comparisons, where fields is a positive decimal integer. A field is the maximal string matched by the basic regular expression:

```
[[:blank:]]*[^[:blank:]]*
```

If the fields option-argument specifies more fields than appear on an input line, a null string shall be used for comparison.
-s chars Ignore the first chars characters when doing comparisons, where chars shall be a positive decimal integer. If specified in conjunction with the $-\mathbf{f}$ option, the first chars characters after the first fields fields shall be ignored. If the chars optionargument specifies more characters than remain on an input line, a null string shall be used for comparison.
$-\mathbf{u} \quad$ Suppress the writing of lines that are repeated in the input.

## OPERANDS

The following operands shall be supported:
input_file A pathname of the input file. If the input_file operand is not specified, or if the input_file is ' $-\prime$ ', the standard input shall be used.
output_file A pathname of the output file. If the output_file operand is not specified, the standard output shall be used. The results are unspecified if the file named by output_file is the file named by input_file.

## STDIN

The standard input shall be used only if no input_file operand is specified or if input_file is ' ${ }^{\prime}$ '. See the INPUT FILES section.

## INPUT FILES

The input file shall be a text file.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of uniq:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.

LC_COLLATE
Determine the locale for ordering rules.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters constitute a <blank> in the current locale.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall be used only if no output_file operand is specified. See the OUTPUT FILES section.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

If the -c option is specified, the output file shall be empty or each line shall be of the form:
"\%d \%s", <number of duplicates>, <line>
otherwise, the output file shall be empty or each line shall be of the form:
"\%s", <line>

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 The utility executed successfully.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The sort utility can be used to cause repeated lines to be adjacent in the input file.

## EXAMPLES

The following input file data (but flushed left) was used for a test series on uniq:

```
#01 foo0 bar0 foo1 bar1
#02 bar0 foo1 bar1 foo1
#03 foo0 bar0 foo1 bar1
#04
#05 foo0 bar0 foo1 bar1
#06 foo0 bar0 foo1 bar1
#07 bar0 foo1 bar1 foo0
```

What follows is a series of test invocations of the uniq utility that use a mixture of uniq options against the input file data. These tests verify the meaning of adjacent. The uniq utility views the input data as a sequence of strings delimited by ' $\backslash \mathrm{n}^{\prime}$. Accordingly, for the fieldsth member of the sequence, uniq interprets unique or repeated adjacent lines strictly relative to the fields +1 th member.

1. This first example tests the line counting option, comparing each line of the input file data starting from the second field:
```
uniq -c -f 1 uniq_OI.t
    1 #01 foo0 bar0 foo1 bar1
    1 #02 bar0 foo1 bar1 foo0
    1 #03 foo0 bar0 fool bar1
    1 #04
    2 #05 foo0 bar0 foo1 bar1
    1 #07 bar0 foo1 bar1 foo0
```

The number ' 2 ', prefixing the fifth line of output, signifies that the uniq utility detected a pair of repeated lines. Given the input data, this can only be true when uniq is run using the - $\mathbf{f} \mathbf{1}$ option (which shall cause unig to ignore the first field on each input line).
2. The second example tests the option to suppress unique lines, comparing each line of the input file data starting from the second field:

```
uniq -d -f 1 uniq_OI.t
#05 foo0 bar0 fool bar1
```

3. This test suppresses repeated lines, comparing each line of the input file data starting from the second field:
```
uniq -u -f 1 uniq_0I.t
#01 foo0 bar0 fool bar1
#02 bar0 foo1 bar1 foo1
#03 foo0 bar0 fool bar1
#04
#07 bar0 foo1 bar1 foo0
```

4. This suppresses unique lines, comparing each line of the input file data starting from the third character:
```
uniq -d -s 2 uniq_0I.t
```

In the last example, the uniq utility found no input matching the above criteria.

## RATIONALE

Some historical implementations have limited lines to be 1080 bytes in length, which does not meet the implied \{LINE_MAX\} limit.

Earlier versions of this standard allowed the -number and +number options. These options are no longer specified by this standard but may be present in some implementations.

## FUTURE DIRECTIONS

None.

comm, sort

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The obsolescent SYNOPSIS and associated text are removed.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/40 is applied, adding LC_COLLATE to the ENVIRONMENT VARIABLES section, and changing "the application shall ensure that" in the OUTPUT FILES section.

Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying that ' + ' may be recognized as an option delimiter in the OPTIONS section.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
unlink - call the unlink () function

## SYNOPSIS

xSI unlink file

## DESCRIPTION

The unlink utility shall perform the function call:
unlink(file);
A user may need appropriate privilege to invoke the unlink utility.

## OPTIONS

None.

## OPERANDS

The following operands shall be supported:
file The pathname of an existing file.

## STDIN

Not used.

## INPUT FILES

Not used.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of unlink:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## CHANGE HISTORY

First released in Issue 5.

## NAME

uucp - system-to-system copy

## SYNOPSIS

uv uucp [-cCdfjmr] [-n user] source-file... destination-file

## DESCRIPTION

The $и и с р$ utility shall copy files named by the source-file argument to the destination-file argument. The files named can be on local or remote systems.
The uиср utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8 -bit data and filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646: 1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used, and that only characters defined in the portable filename character set be used for naming files. The protocol for transfer of files is unspecified by IEEE Std 1003.1-200x.
Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

## OPTIONS

The uucp utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:

| $-\mathbf{c}$ | Do not copy local file to the spool directory for transfer to the remote machine <br> (default). |
| :--- | :--- |
| $-\mathbf{C}$ | Force the copy of local files to the spool directory for transfer. |
| $-\mathbf{d}$ | Make all necessary directories for the file copy (default). |
| $-\mathbf{f}$ | Do not make intermediate directories for the file copy. |
| $-\mathbf{j}$ | Write the job identification string to standard output. This job identification can be <br> used by uustat to obtain the status or terminate a job. |
| $-\mathbf{m}$ | Send mail to the requester when the copy is completed. |
| $-\mathbf{n}$ user | Notify user on the remote system that a file was sent. |
| $-\mathbf{r}$ | Do not start the file transfer; just queue the job. |

## OPERANDS

The following operands shall be supported:
destination-file, source-file
A pathname of a file to be copied to, or from, respectively. Either name can be a pathname on the local machine, or can have the form:
system-name!pathname
where system-name is taken from a list of system names that uucp knows about. The destination system-name can also be a list of names such as:

system-name!system-name!...!system-name!pathname
in which case, an attempt is made to send the file via the specified route to the destination. Care should be taken to ensure that intermediate nodes in the route are willing to forward information.
The shell pattern matching notation characters '?','*', and " [...]" appearing in pathname shall be expanded on the appropriate system.

Pathnames can be one of:

1. An absolute pathname.
2. A pathname preceded by ${ }^{\sim} u s e r$ where user is a login name on the specified system and is replaced by that user's login directory. Note that if an invalid login is specified, the default is to the public directory (called PUBDIR; the actual location of PUBDIR is implementation-defined).
3. A pathname preceded by $\sim /$ destination where destination is appended to PUBDIR.

Note: This destination is treated as a filename unless more than one file is being transferred by this request or the destination is already a directory. To ensure that it is a directory, follow the destination with a '/'. For example, $\sim / \mathrm{dan} /$ as the destination makes the directory PUBDIR/dan if it does not exist and puts the requested files in that directory.
4. Anything else shall be prefixed by the current directory.

If the result is an erroneous pathname for the remote system, the copy shall fail. If the destination-file is a directory, the last part of the source-file name shall be used.
The read, write, and execute permissions given by $и и с р$ are implementationdefined.

## STDIN

Not used.

## INPUT FILES

The files to be copied are regular files.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of $u и с p$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements within bracketed filename patterns.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes within bracketed filename patterns (for example, "' [ [:lower: ]] *'").
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The output files (which may be on other systems) are copies of the input files.
If $-\mathbf{m}$ is used, mail files are modified.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

This utility is part of the UUCP Utilities option and need not be supported by all implementations,
The domain of remotely accessible files can (and for obvious security reasons usually should) be severely restricted.
Note that the ' !' character in addresses has to be escaped when using csh as a command interpreter because of its history substitution syntax. For ksh and sh the escape is not necessary, but may be used.

As noted above, shell metacharacters appearing in pathnames are expanded on the appropriate system. On an internationalized system, this is done under the control of local settings of LC_COLLATE and LC_CTYPE. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.
The UN margin codes and associated shading are removed from the $-\mathbf{C}, \mathbf{- f},-\mathbf{j},-\mathbf{n}$, and $-\mathbf{r}$ options in response to The Open Group Base Resolution bwg2001-003.

Issue 7
SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
uudecode - decode a binary file

## SYNOPSIS

```
uudecode [-o outfile] [file]
```

## DESCRIPTION

The uudecode utility shall read a file, or standard input if no file is specified, that includes data created by the uuencode utility. The uudecode utility shall scan the input file, searching for data compatible with one of the formats specified in uuencode, and attempt to create or overwrite the file described by the data (or overridden by the -o option). The pathname shall be contained in the data or specified by the -o option. The file access permission bits and contents for the file to be produced shall be contained in that data. The mode bits of the created file (other than standard output) shall be set from the file access permission bits contained in the data; that is, other attributes of the mode, including the file mode creation mask (see umask), shall not affect the file being produced. If either of the op characters ${ }^{\prime+}$ ' and ${ }^{\prime} \mathbf{'}^{\prime}$ (see chmod) are specified in symbolic mode, the initial mode on which those operations are based is unspecified.
If the pathname of the file to be produced exists, and the user does not have write permission on that file, uudecode shall terminate with an error. If the pathname of the file to be produced exists, and the user has write permission on that file, the existing file shall be overwritten.
If the input data was produced by uuencode on a system with a different number of bits per byte than on the target system, the results of uudecode are unspecified.

## OPTIONS

The uudecode utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following option shall be supported by the implementation:
-o outfile A pathname of a file that shall be used instead of any pathname contained in the input data. Specifying an outfile option-argument of /dev/stdout shall indicate standard output.

## OPERANDS

The following operand shall be supported:
file The pathname of a file containing the output of uuencode.

## STDIN

See the INPUT FILES section.

## INPUT FILES

The input files shall be files containing the output of uuencode.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of uudecode:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

If the file data header encoded by uuencode is - or /dev/stdout, or the -o /dev/stdout option overrides the file data, the standard output shall be in the same format as the file originally encoded by uuencode. Otherwise, the standard output shall not be used.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

The output file shall be in the same format as the file originally encoded by uuencode.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The user who is invoking uudecode must have write permission on any file being created.
The output of uuencode is essentially an encoded bit stream that is not cognizant of byte boundaries. It is possible that a 9-bit byte target machine can process input from an 8-bit source, if it is aware of the requirement, but the reverse is unlikely to be satisfying. Of course, the only data that is meaningful for such a transfer between architectures is generally character data.

## EXAMPLES

None.

## RATIONALE

Input files are not necessarily text files, as stated by an early proposal. Although the uuencode output is a text file, that output could have been wrapped within another file or mail message that is not a text file.

The -o option is not historical practice, but was added at the request of WG15 so that the user could override the target pathname without having to edit the input data itself.

In early drafts, the [ $-\mathbf{o}$ outfile

## FUTURE DIRECTIONS

None.

## SEE ALSO

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The - o outfile option is added, as specified in the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/35 is applied, clarifying in the DESCRIPTION that the initial mode used if either of the op characters is ' $+^{\prime}$ or $r^{\prime}$ ' is unspecified.
Issue 7
The uudecode utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
.

NAME
uuencode - encode a binary file

## SYNOPSIS

```
uuencode [-m] [file] decode_pathname
```

## DESCRIPTION

The uиencode utility shall write an encoded version of the named input file, or standard input if no file is specified, to standard output. The output shall be encoded using one of the algorithms described in the STDOUT section and shall include the file access permission bits (in chmod octal or symbolic notation) of the input file and the decode_pathname, for re-creation of the file on another system that conforms to this volume of IEEE Std 1003.1-200x.

## OPTIONS

The uuencode utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following option shall be supported by the implementation:
-m Encode the output using the MIME Base64 algorithm described in STDOUT. If -m is not specified, the historical algorithm described in STDOUT shall be used.

## OPERANDS

The following operands shall be supported:
decode_pathname
The pathname of the file into which the uudecode utility shall place the decoded file. Specifying a decode_pathname operand of /dev/stdout shall indicate that uudecode is to use standard output. If there are characters in decode_pathname that are not in the portable filename character set the results are unspecified.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of uuencode:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

## uuencode Base64 Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:
"begin-base $64 \Delta \% s \Delta \% s \backslash n ",<m o d e>,<d e c o d e \_p a t h n a m e>$
and ends with the line:
" $=====\ \mathrm{n}$ "
In both cases, the lines shall have no preceding or trailing <blank>s.
The encoding process represents 24-bit groups of input bits as output strings of four encoded characters. Proceeding from left to right, a 24 -bit input group shall be formed by concatenating three 8 -bit input groups. Each 24 -bit input group then shall be treated as four concatenated 6 -bit groups, each of which shall be translated into a single digit in the Base64 alphabet. When encoding a bit stream via the Base64 encoding, the bit stream shall be presumed to be ordered with the most-significant bit first. That is, the first bit in the stream shall be the high-order bit in the first byte, and the eighth bit shall be the low-order bit in the first byte, and so on. Each 6-bit group is used as an index into an array of 64 printable characters, as shown in Table 4-21 (on page 979).

Table 4-21 uuencode Base64 Values

| Value | Encoding | Value | Encoding | Value | Encoding | Value | Encoding |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | A | 17 | R | 34 | i | 51 | z |
| 1 | B | 18 | S | 35 | j | 52 | 0 |
| 2 | C | 19 | T | 36 | k | 53 | 1 |
| 3 | D | 20 | U | 37 | l | 54 | 2 |
| 4 | E | 21 | V | 38 | m | 55 | 3 |
| 5 | F | 22 | W | 39 | n | 56 | 4 |
| 6 | G | 23 | X | 40 | 0 | 57 | 5 |
| 7 | H | 24 | Y | 41 | p | 58 | 6 |
| 8 | I | 25 | Z | 42 | q | 59 | 7 |
| 9 | J | 26 | a | 43 | r | 60 | 8 |
| 10 | K | 27 | b | 44 | s | 61 | 9 |
| 11 | L | 28 | C | 45 | t | 62 | + |
| 12 | M | 29 | d | 46 | u | 63 | $/$ |
| 13 | N | 30 | e | 47 | V |  |  |
| 14 | O | 31 | f | 48 | w | $(\mathrm{pad})$ | $=$ |
| 15 | P | 32 | g | 49 | x |  |  |
| 16 | Q | 33 | h | 50 | Y |  |  |

The character referenced by the index shall be placed in the output string.
The output stream (encoded bytes) shall be represented in lines of no more than 76 characters each. All line breaks or other characters not found in the table shall be ignored by decoding software (see uudecode).
Special processing shall be performed if fewer than 24 bits are available at the end of a message
or encapsulated part of a message. A full encoding quantum shall always be completed at the end of a message. When fewer than 24 input bits are available in an input group, zero bits shall be added (on the right) to form an integral number of 6 -bit groups. Output character positions that are not required to represent actual input data shall be set to the character ${ }^{\prime}={ }^{\prime}$. Since all Base64 input is an integral number of octets, only the following cases can arise:

1. The final quantum of encoding input is an integral multiple of 24 bits; here, the final unit of encoded output shall be an integral multiple of 4 characters with no ${ }^{\prime}=\prime$ padding.
2. The final quantum of encoding input is exactly 16 bits; here, the final unit of encoded output shall be three characters followed by one ${ }^{\prime}=$ ' padding character.
3. The final quantum of encoding input is exactly 8 bits; here, the final unit of encoded output shall be two characters followed by two ${ }^{\prime}=$ ' padding characters.
A terminating $"====="$ evaluates to nothing and denotes the end of the encoded data.

## uuencode Historical Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:

```
"begin}\Delta%s\Delta%s\n" <mode>, <decode_pathname>
```

and ends with the line:

```
"end\n"
```

In both cases, the lines shall have no preceding or trailing <blank>s.
The algorithm that shall be used for lines in between begin and end takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets shall be converted to characters by adding a value of $0 \times 20$ to each octet, so that each octet is in the range $[0 \times 20,0 \times 5 \mathrm{f}]$, and then it shall be assumed to represent a printable character in the ISO/IEC 646: 1991 standard encoded character set. It then shall be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet $0 \times 41$, representing ' $A$ ', would be translated to ${ }^{\prime} A^{\prime}$ in the current codeset, such as $0 \times 1$ if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet shall be shifted left and combined with the most significant bits of the second octet shifted right. Thus the three octets $A, B, C$ shall be converted into the four octets:

```
\(0 \times 20+((A \gg 2 \quad) \& 0 \times 3 F)\)
\(0 \times 20+(((A \ll 4) \quad((B \gg 4) \& 0 x F)) \& 0 \times 3 F)\)
\(0 \times 20+(((B \ll 2) \quad((C \gg 6) \& 0 \times 3)) \& 0 \times 3 F)\)
\(0 \times 20+((\mathrm{C})) \& 0 \times 3 F)\)
```

These octets then shall be translated into the local character set.
Each encoded line contains a length character, equal to the number of characters to be decoded plus $0 \times 20$ translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line shall be 45 .

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The file is expanded by 35 percent (each three octets become four, plus control information) causing it to take longer to transmit.
Since this utility is intended to create files to be used for data interchange between systems with possibly different codesets, and to represent binary data as a text file, the ISO/IEC 646:1991 standard was chosen for a midpoint in the algorithm as a known reference point. The output from uuencode is a text file on the local system. If the output were in the ISO/IEC 646:1991 standard codeset, it might not be a text file (at least because the <newline>s might not match), and the goal of creating a text file would be defeated. If this text file was then carried to another machine with the same codeset, it would be perfectly compatible with that system's uudecode. If it was transmitted over a mail system or sent to a machine with a different codeset, it is assumed that, as for every other text file, some translation mechanism would convert it (by the time it reached a user on the other system) into an appropriate codeset. This translation only makes sense from the local codeset, not if the file has been put into a ISO/IEC 646: 1991 standard representation first. Similarly, files processed by uuencode can be placed in pax archives, intermixed with other text files in the same codeset.

## EXAMPLES

None.

## RATIONALE

A new algorithm was added at the request of the international community to parallel work in RFC 2045 (MIME). As with the historical uuencode format, the Base64 Content-Transfer-Encoding is designed to represent arbitrary sequences of octets in a form that is not humanly readable. A 65-character subset of the ISO/IEC 646: 1991 standard is used, enabling 6 bits to be represented per printable character. (The extra 65 th character, $\prime^{\prime}=\prime$, is used to signify a special processing function.)
This subset has the important property that it is represented identically in all versions of the ISO/IEC 646: 1991 standard, including US ASCII, and all characters in the subset are also represented identically in all versions of EBCDIC. The historical uuencode algorithm does not share this property, which is the reason that a second algorithm was added to the ISO POSIX-2 standard.
The string $"====="$ was used for the termination instead of the end used in the original format because the latter is a string that could be valid encoded input.

In an early draft, the $\mathbf{- m}$ option was named $\mathbf{- b}$ (for Base64), but it was renamed to reflect its relationship to the RFC 2045. A $-\mathbf{u}$ was also present to invoke the default algorithm, but since this was not historical practice, it was omitted as being unnecessary.

See the RATIONALE section in uudecode for the derivation of the /dev/stdout symbol.

## FUTURE DIRECTIONS

None.

## SEE ALSO

chmod, mailx, uudecode

## CHANGE HISTORY

First released in Issue 4.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The Base64 algorithm and the ability to output to /dev/stdout are added as specified in the IEEE P1003.2b draft standard.

## Issue 7

The uuencode utility is moved from the User Portability Utilities option to the Base. User Portability Utilities is now an option for interactive utilities.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

uustat - uucp status inquiry and job control

## SYNOPSIS

uU

```
uustat [-q|-k jobid|-r jobid]
    uustat [-s system] [-u user]
```

## DESCRIPTION

The uustat utility shall display the status of, or cancel, previously specified uиср requests, or provide general status on $u и с p$ connections to other systems.
When no options are given, uustat shall write to standard output the status of all uucp requests issued by the current user.
Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.

## OPTIONS

The uustat utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
$-\mathbf{q} \quad$ Write the jobs queued for each machine.
$-\mathbf{k}$ jobid Kill the uиcp request whose job identification is jobid. The application shall ensure that the killed uucp request belongs to the person invoking uustat unless that user has appropriate privileges.
-r jobid Rejuvenate jobid. The files associated with jobid are touched so that their modification time is set to the current time. This prevents the cleanup program from deleting the job until the jobs modification time reaches the limit imposed by the program.
-s system Write the status of all uиср requests for remote system system.
-u user $\quad$ Write the status of all uисp requests issued by user.

## OPERANDS

None.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of uustat:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall consist of information about each job selected, in an unspecified format. The information shall include at least the job ID, the user ID or name, and the remote system name.

## STDERR

The standard error shall be used only for diagnostic messages.
OUTPUT FILES
None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

This utility is part of the UUCP Utilities option and need not be supported by all implementations.

## EXAMPLES

None.

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

ииср

## CHANGE HISTORY

First released in Issue 2.

Issue 6
The normative text is reworded to avoid use of the term "must" for application requirements.
The LC_TIME and TZ entries are removed from the ENVIRONMENT VARIABLES section.
The UN margin code and associated shading are removed from the $-\mathbf{q}$ option in response to The Open Group Base Resolution bwg2001-003.

Issue 7
SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

## NAME

uux - remote command execution

## SYNOPSIS

```
UU uux [-np] command-string
uux [-jnp] command-string
```

## DESCRIPTION

The uux utility shall gather zero or more files from various systems, execute a shell pipeline (see Section 2.9 (on page 47)) on a specified system, and then send the standard output of the command to a file on a specified system. Only the first command of a pipeline can have a systemname! prefix. All other commands in the pipeline shall be executed on the system of the first command.

The following restrictions are applicable to the shell pipeline processed by $u u x$ :

- In gathering files from different systems, pathname expansion shall not be performed by uux. Thus, a request such as:

```
uux "c99 remsys!~/*.c"
```

would attempt to copy the file named literally ${ }^{*} . \mathrm{c}$ to the local system.

- The redirection operators ">>", "<<", ">|", and ">\&" shall not be accepted. Any use of these redirection operators shall cause this utility to write an error message describing the problem and exit with a non-zero exit status.
- The reserved word ! cannot be used at the head of the pipeline to modify the exit status. (See the command-string operand description below.)
- Alias substitution shall not be performed.

A filename can be specified as for $u \boldsymbol{u c p}$; it can be an absolute pathname, a pathname preceded by nname (which is replaced by the corresponding login directory), a pathname specified as $\sim /$ dest (dest is prefixed by the public directory called PUBDIR; the actual location of PUBDIR is implementation-defined), or a simple filename (which is prefixed by uux with the current directory). See ииср for the details.

The execution of commands on remote systems shall take place in an execution directory known to the $u и с р$ system. All files required for the execution shall be put into this directory unless they already reside on that machine. Therefore, the application shall ensure that non-local filenames (without path or machine reference) are unique within the $u u x$ request.
The $u u x$ utility shall attempt to get all files to the execution system. For files that are output files, the application shall ensure that the filename is escaped using parentheses.

The remote system shall notify the user by mail if the requested command on the remote system was disallowed or the files were not accessible. This notification can be turned off by the -n option.

Typical implementations of this utility require a communications line configured to use the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface, but other communications means may be used. On systems where there are no available communications means (either temporarily or permanently), this utility shall write an error message describing the problem and exit with a non-zero exit status.
The uux utility cannot guarantee support for all character encodings in all circumstances. For example, transmission data may be restricted to 7 bits by the underlying network, 8 -bit data and
filenames need not be portable to non-internationalized systems, and so on. Under these circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

Output files shall be created or written, or both, according to the contents of command-string.
If $\mathbf{-} \mathbf{n}$ is not used, mail files shall be modified following any command or file-access failures on the remote system.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

This utility is part of the UUCP Utilities option and need not be supported by all implementations.
Note that, for security reasons, many installations limit the list of commands executable on behalf of an incoming request from $u u x$. Many sites permit little more than the receipt of mail via $u u x$.
Any characters special to the command interpreter should be quoted either by quoting the entire command-string or quoting the special characters as individual arguments.
As noted in ииср, shell pattern matching notation characters appearing in pathnames are expanded on the appropriate local system. This is done under the control of local settings of LC_COLLATE and LC_CTYPE. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.

## EXAMPLES

1. The following command gets file $\mathbf{1}$ from system $\mathbf{a}$ and file $\mathbf{2}$ from system $\mathbf{b}$, executes diff on the local system, and puts the results in file.diff in the local PUBDIR directory. (PUBDIR is the $u u c p$ public directory on the local system.)
uux "!diff a!/usr/file1 b!/a4/file2 >!~/file.diff"
2. The following command fails because $u u x$ places all files copied to a system in the same working directory. Although the files xyz are from two different systems, their filenames are the same and conflict.
uux "!diff a!/usr1/xyz b!/usr2/xyz >!~/xyz.diff"
3. The following command succeeds (assuming diff is permitted on system a) because the file local to system a is not copied to the working directory, and hence does not conflict with the file from system $\mathbf{c}$.
uux "a!diff a!/usr/xyz c!/usr/xyz >!~/xyz.diff"

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The obsolescent SYNOPSIS is removed.
The normative text is reworded to avoid use of the term "must" for application requirements.
The UN margin code and associated shading are removed from the $-\mathbf{j}$ option in response to The Open Group Base Resolution bwg2001-003.

Issue 7
SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

## NAME

val - validate SCCS files (DEVELOPMENT)

## SYNOPSIS

xSI val -
val [-s] [-m name] [-r SID] [-y type] file...

## DESCRIPTION

The val utility shall determine whether the specified file is an SCCS file meeting the characteristics specified by the options.

## OPTIONS

The val utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that the usage of the ${ }^{\prime} \prime^{\prime}$ operand is not strictly as intended by the guidelines (that is, reading options and operands from standard input).

The following options shall be supported:

| -m name | Specify a name, which is compared with the SCCS \%M\% keyword in file; see get. |
| :---: | :---: |
| -r SID | Specify a SID (SCCS Identification String), an SCCS delta number. A check shall be made to determine whether the SID is ambiguous (for example, $\mathbf{- r} \mathbf{1}$ is ambiguous because it physically does not exist but implies $1.1,1.2$, and so on, which may exist) or invalid (for example, -r 1.0 or -r 1.1.0 are invalid because neither case can exist as a valid delta number). If the SID is valid and not ambiguous, a check shall be made to determine whether it actually exists. |
| -S | Silence the diagnostic message normally written to standard output for any error that is detected while processing each named file on a given command line. |
| -y type | Specify a type, which shall be compared with the SCCS \%Y\% keyword in file; see get. |

## OPERANDS

The following operands shall be supported:
file A pathname of an existing SCCS file. If exactly one file operand appears, and it is $' \quad{ }^{\prime}$, the standard input shall be read: each line shall be independently processed as if it were a command line argument list. (However, the line is not subjected to any of the shell word expansions, such as parameter expansion or quote removal.)

## STDIN

The standard input shall be a text file used only when the file operand is specified as ${ }^{\prime} \mathbf{-}^{\prime}$.

## INPUT FILES

Any SCCS files processed shall be files of an unspecified format.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of val:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error, and informative messages written to standard output.

NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The standard output shall consist of informative messages about either:

1. Each file processed
2. Each command line read from standard input

If the standard input is not used, for each file operand yielding a discrepancy, the output line shall have the following format:
"\%s: \%s\n", <pathname>, <unspecified string>
If standard input is used, a line of input shall be written before each of the preceding lines for files containing discrepancies:
"\%s:\n", <input line>

## STDERR

Not used.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The 8-bit code returned by val shall be a disjunction of the possible errors; that is, it can be interpreted as a bit string where set bits are interpreted as follows:
$0 \times 80=$ Missing file argument.
$0 \times 40=$ Unknown or duplicate option.
$0 \times 20=$ Corrupted SCCS file.
$0 \times 10=$ Cannot open file or file not SCCS.
$0 \times 08=$ SID is invalid or ambiguous.
$0 \times 04=$ SID does not exist.
$0 \times 02=\% \mathbf{Y} \%,-\mathbf{y}$ mismatch.
$0 \times 01=\% \mathbf{M} \%,-\mathbf{m}$ mismatch.
Note that val can process two or more files on a given command line and can process multiple command lines (when reading the standard input). In these cases an aggregate code shall be returned: a logical OR of the codes generated for each command line and file processed.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

Since the val exit status sets the $0 \times 80$ bit, shell applications checking "\$?" cannot tell if it terminated due to a missing file argument or receipt of a signal.

## EXAMPLES

In a directory with three SCCS files-s.x (of $\mathbf{t}$ type "text"), s.y, and $\mathbf{s . z}$ (a corrupted file)—the following command could produce the output shown:

```
val - <<EOF
-y source s.x
-m y s.y
s.z
EOF
-y source s.x
        s.x: %Y%, -y mismatch
    S.z
        s.z: corrupted SCCS file
```

## RATIONALE

None.

## FUTURE DIRECTIONS

None.

admin, delta, get, prs

## CHANGE HISTORY

First released in Issue 2.
Issue 6
The Open Group Corrigendum U025/4 is applied, correcting a typographical error in the EXIT STATUS.

Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
vi - screen-oriented (visual) display editor

## SYNOPSIS

UP vi [-rR] [-c command] [-t tagstring] [-w size] [file...]

## DESCRIPTION

This utility shall be provided on systems that both support the User Portability Utilities option and define the POSIX2_CHAR_TERM symbol. On other systems it is optional.
The $v i$ (visual) utility is a screen-oriented text editor. Only the open and visual modes of the editor are described in IEEE Std 1003.1-200x; see the line editor ex for additional editing capabilities used in $v i$. The user can switch back and forth between $v i$ and $e x$ and execute $e x$ commands from within $v i$.

This reference page uses the term edit buffer to describe the current working text. No specific implementation is implied by this term. All editing changes are performed on the edit buffer, and no changes to it shall affect any file until an editor command writes the file.

When using $v i$, the terminal screen acts as a window into the editing buffer. Changes made to the editing buffer shall be reflected in the screen display; the position of the cursor on the screen shall indicate the position within the editing buffer.

Certain terminals do not have all the capabilities necessary to support the complete vi definition. When these commands cannot be supported on such terminals, this condition shall not produce an error message such as "not an editor command" or report a syntax error. The implementation may either accept the commands and produce results on the screen that are the result of an unsuccessful attempt to meet the requirements of this volume of IEEE Std 1003.1-200x or report an error describing the terminal-related deficiency.

## OPTIONS

The $v i$ utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines, except that ' + ' may be recognized as an option delimiter as well as '-'.

The following options shall be supported:
-c command See the ex command description of the -c option.
$-\mathbf{r} \quad$ See the $e x$ command description of the $-\mathbf{r}$ option.
-R See the ex command description of the -R option.
$-\mathbf{t}$ tagstring See the ex command description of the $-\mathbf{t}$ option.
-w size See the ex command description of the -w option.

## OPERANDS

See the OPERANDS section of the $e x$ command for a description of the operands supported by the vi command.

## STDIN

If standard input is not a terminal device, the results are undefined. The standard input consists of a series of commands and input text, as described in the EXTENDED DESCRIPTION section.
If a read from the standard input returns an error, or if the editor detects an end-of-file condition from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

## INPUT FILES

See the INPUT FILES section of the ex command for a description of the input files supported by the $v i$ command.

## ENVIRONMENT VARIABLES

See the ENVIRONMENT VARIABLES section of the ex command for the environment variables that affect the execution of the $v i$ command.

## ASYNCHRONOUS EVENTS

See the ASYNCHRONOUS EVENTS section of the $e x$ for the asynchronous events that affect the execution of the vi command.

## STDOUT

If standard output is not a terminal device, undefined results occur.
Standard output may be used for writing prompts to the user, for informational messages, and for writing lines from the file.

## STDERR

If standard output is not a terminal device, undefined results occur.
The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

See the OUTPUT FILES section of the ex command for a description of the output files supported by the vi command.

## EXTENDED DESCRIPTION

If the terminal does not have the capabilities necessary to support an unspecified portion of the vi definition, implementations shall start initially in ex mode or open mode. Otherwise, after initialization, vi shall be in command mode; text input mode can be entered by one of several commands used to insert or change text. In text input mode, <ESC> can be used to return to command mode; other uses of <ESC> are described later in this section; see Terminate Command or Input Mode (on page 1002).

## Initialization in ex and vi

See Initialization in ex and vi for a description of $e x$ and $v i$ initialization for the $v i$ utility.
Command Descriptions in vi
The following symbols are used in this reference page to represent arguments to commands.
buffer See the description of buffer in the EXTENDED DESCRIPTION section of the ex utility; see Command Descriptions in ex (on page 370).
In open and visual mode, when a command synopsis shows both [buffer] and [count] preceding the command name, they can be specified in either order.
count A positive integer used as an optional argument to most commands, either to give a repeat count or as a size. This argument is optional and shall default to 1 unless otherwise specified.
The Synopsis lines for the vi commands <control>-G, <control>-L, <control>-R, <control>-], \%, \&, ${ }^{\wedge}, \mathbf{D}, \mathbf{m}, \mathbf{M}, \mathbf{Q}, \mathbf{u}, \mathbf{U}$, and $\mathbf{Z Z}$ do not have count as an optional argument. Regardless, it shall not be an error to specify a count to these commands, and any specified count shall be ignored.
motion An optional trailing argument used by the $!,<,>, \mathbf{c}, \mathbf{d}$, and $\mathbf{y}$ commands, which is used to indicate the region of text that shall be affected by the command. The motion can be either one of the command characters repeated or one of several other vi commands (listed in the following table). Each of the applicable commands specifies the region of
text matched by repeating the command; each command that can be used as a motion command specifies the region of text it affects.
Commands that take motion arguments operate on either lines or characters, depending on the circumstances. When operating on lines, all lines that fall partially or wholly within the text region specified for the command shall be affected. When operating on characters, only the exact characters in the specified text region shall be affected. Each motion command specifies this individually.

When commands that may be motion commands are not used as motion commands, they shall set the current position to the current line and column as specified.

The following commands shall be valid cursor motion commands:

| <apostrophe> | $($ | - | $j$ | H |
| :--- | :--- | :--- | :--- | :--- |
| <carriage-return> | $)$ | $\$$ | k | L |
| <comma> | $[[$ | $\%$ | l | M |
| <control>-H | $]]$ | - | n | N |
| <control>-N | $\{$ | $;$ | t | T |
| <control>-P | $\}$ | $?$ | w | W |
| <grave accent> | a | b | B |  |
| <newline> | + | e | E |  |
| <space> | l | f | F |  |
| <zero> | $/$ | h | G |  |

Any count that is specified to a command that has an associated motion command shall be applied to the motion command. If a count is applied to both the command and its associated motion command, the effect shall be multiplicative.
The following symbols are used in this section to specify locations in the edit buffer: current character

The character that is currently indicated by the cursor.
end of a line
The point located between the last non-<newline> (if any) and the terminating <newline> of a line. For an empty line, this location coincides with the beginning of the line.
end of the edit buffer
The location corresponding to the end of the last line in the edit buffer.
The following symbols are used in this section to specify command actions:
bigword In the POSIX locale, vi shall recognize four kinds of bigwords:

1. A maximal sequence of non-<blank>s preceded and followed by <blank>s or the beginning or end of a line or the edit buffer
2. One or more sequential blank lines
3. The first character in the edit buffer
4. The last non-<newline> in the edit buffer
word In the POSIX locale, vi shall recognize five kinds of words:
5. A maximal sequence of letters, digits, and underscores, delimited at both ends by:

- Characters other than letters, digits, or underscores
- The beginning or end of a line
- The beginning or end of the edit buffer

2. A maximal sequence of characters other than letters, digits, underscores, or <blank>s, delimited at both ends by:

- A letter, digit, underscore
— <blank>s
- The beginning or end of a line
- The beginning or end of the edit buffer

3. One or more sequential blank lines
4. The first character in the edit buffer
5. The last non-<newline> in the edit buffer

## section boundary

A section boundary is one of the following:

1. A line whose first character is a <form-feed>
2. A line whose first character is an open curly brace ( ${ }^{\prime}\left\{{ }^{\prime}\right.$ )
3. A line whose first character is a period and whose second and third characters match a two-character pair in the sections edit option (see ed)
4. A line whose first character is a period and whose only other character matches the first character of a two-character pair in the sections edit option, where the second character of the two-character pair is a <space>
5. The first line of the edit buffer
6. The last line of the edit buffer if the last line of the edit buffer is empty or if it is a ll or I command; otherwise, the last non-<newline> of the last line of the edit buffer
paragraph boundary
A paragraph boundary is one of the following:
7. A section boundary
8. A line whose first character is a period and whose second and third characters match a two-character pair in the paragraphs edit option (see ed)
9. A line whose first character is a period and whose only other character matches the first character of a two-character pair in the paragraphs edit option, where the second character of the two-character pair is a <space>
10. One or more sequential blank lines
remembered search direction
See the description of remembered search direction in ed.
sentence boundary
A sentence boundary is one of the following:
11. A paragraph boundary
12. The first non-<blank> that occurs after a paragraph boundary
13. The first non-<blank> that occurs after a period (' .' ), exclamation mark (' ! ' ), or question mark ( ${ }^{\prime} ?^{\prime}$ ), followed by two <space>s or the end of a line; any number of closing parenthesis (' )' ), closing brackets (' ] ' ), double quote ( ${ }^{\prime} \mathrm{l}^{\prime}$ ), or single quote $\left(r^{\prime \prime}\right)$ characters can appear between the punctuation mark and the two <space>s or end-of-line

In the remainder of the description of the vi utility, the term "buffer line" refers to a line in the edit buffer and the term "display line" refers to the line or lines on the display screen used to display one buffer line. The term "current line" refers to a specific "buffer line".

If there are display lines on the screen for which there are no corresponding buffer lines because they correspond to lines that would be after the end of the file, they shall be displayed as a single tilde ( ${ }^{\prime} \sim$ ' ) character, plus the terminating <newline>.
The last line of the screen shall be used to report errors or display informational messages. It shall also be used to display the input for "line-oriented commands" (/, ?, :, and !). When a lineoriented command is executed, the editor shall enter text input mode on the last line on the screen, using the respective command characters as prompt characters. (In the case of the ! command, the associated motion shall be entered by the user before the editor enters text input mode.) The line entered by the user shall be terminated by a <newline>, $a$ non-<control>-V-escaped <carriage-return>, or unescaped <ESC>. It is unspecified if more characters than require a display width minus one column number of screen columns can be entered.

If any command is executed that overwrites a portion of the screen other than the last line of the screen (for example, the ex suspend or ! commands), other than the ex shell command, the user shall be prompted for a character before the screen is refreshed and the edit session continued.
<tab>s shall take up the number of columns on the screen set by the tabstop edit option (see ed), unless there are less than that number of columns before the display margin that will cause the displayed line to be folded; in this case, they shall only take up the number of columns up to that boundary.
The cursor shall be placed on the current line and relative to the current column as specified by each command described in the following sections.

In open mode, if the current line is not already displayed, then it shall be displayed.
In visual mode, if the current line is not displayed, then the lines that are displayed shall be expanded, scrolled, or redrawn to cause an unspecified portion of the current line to be displayed. If the screen is redrawn, no more than the number of display lines specified by the value of the window edit option shall be displayed (unless the current line cannot be completely displayed in the number of display lines specified by the window edit option) and the current line shall be positioned as close to the center of the displayed lines as possible (within the constraints imposed by the distance of the line from the beginning or end of the edit buffer). If the current line is before the first line in the display and the screen is scrolled, an unspecified portion of the current line shall be placed on the first line of the display. If the current line is after the last line in the display and the screen is scrolled, an unspecified portion of the current line shall be placed on the last line of the display.

In visual mode, if a line from the edit buffer (other than the current line) does not entirely fit into the lines at the bottom of the display that are available for its presentation, the editor may choose not to display any portion of the line. The lines of the display that do not contain text from the edit buffer for this reason shall each consist of a single ' @' character.

In visual mode, the editor may choose for unspecified reasons to not update lines in the display to correspond to the underlying edit buffer text. The lines of the display that do not correctly correspond to text from the edit buffer for this reason shall consist of a single ' @' character (plus the terminating <newline>), and the <control>-R command shall cause the editor to update the
screen to correctly represent the edit buffer.
Open and visual mode commands that set the current column set it to a column position in the display, and not a character position in the line. In this case, however, the column position in the display shall be calculated for an infinite width display; for example, the column related to a character that is part of a line that has been folded onto additional screen lines will be offset from the display line column where the buffer line begins, not from the beginning of a particular display line.

The display cursor column in the display is based on the value of the current column, as follows, with each rule applied in turn:

1. If the current column is after the last display line column used by the displayed line, the display cursor column shall be set to the last display line column occupied by the last non-<newline> in the current line; otherwise, the display cursor column shall be set to the current column.
2. If the character of which some portion is displayed in the display line column specified by the display cursor column requires more than a single display line column:
a. If in text input mode, the display cursor column shall be adjusted to the first display line column in which any portion of that character is displayed.
b. Otherwise, the display cursor column shall be adjusted to the last display line column in which any portion of that character is displayed.
The current column shall not be changed by these adjustments to the display cursor column.
If an error occurs during the parsing or execution of a vi command:

- The terminal shall be alerted. Execution of the vi command shall stop, and the cursor (for example, the current line and column) shall not be further modified.
- Unless otherwise specified by the following command sections, it is unspecified whether an informational message shall be displayed.
- Any partially entered vi command shall be discarded.
- If the $v i$ command resulted from a map expansion, all characters from that map expansion shall be discarded, except as otherwise specified by the map command (see ed).
- If the $v i$ command resulted from the execution of a buffer, no further commands caused by the execution of the buffer shall be executed.

Page Backwards
Synopsis: [count] <control>-B
If in open mode, the <control>-B command shall behave identically to the $\mathbf{z}$ command. Otherwise, if the current line is the first line of the edit buffer, it shall be an error.

If the window edit option is less than 3, display a screen where the last line of the display shall be some portion of:

```
(current first line) -1
```

otherwise, display a screen where the first line of the display shall be some portion of:
(current first line) - count $x$ ((window edit option) -2)
If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.
Current line: If no lines from the previous display remain on the screen, set to the last line of the display; otherwise, set to (line - the number of new lines displayed on this screen).

Current column: Set to non-<blank>.

## Scroll Forward

Synopsis: [count] <control>-D
If the current line is the last line of the edit buffer, it shall be an error.
If no count is specified, count shall default to the count associated with the previous <control>-D or <control>-U command. If there was no previous <control>-D or <control>-U command, count shall default to the value of the scroll edit option.
If in open mode, write lines starting with the line after the current line, until count lines or the last line of the file have been written.
Current line: If the current line + count is past the last line of the edit buffer, set to the last line of the edit buffer; otherwise, set to the current line + count.
Current column: Set to non-<blank>.

## Scroll Forward by Line

Synopsis: [count] <control>-E
Display the line count lines after the last line currently displayed.
If the last line of the edit buffer is displayed, it shall be an error. If there is no line count lines after the last line currently displayed, the last line of the display shall display some portion of the last line of the edit buffer.
Current line: Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.
Current column: Unchanged.
Page Forward
Synopsis: [count] <control>-F
If in open mode, the <control>-F command shall behave identically to the $\mathbf{z}$ command. Otherwise, if the current line is the last line of the edit buffer, it shall be an error.
If the window edit option is less than 3, display a screen where the first line of the display shall be some portion of:

```
(current last line) +1
```

otherwise, display a screen where the first line of the display shall be some portion of:

```
(current first line) + count x ((window edit option) -2)
```

If this calculation would result in a line that is after the last line of the edit buffer, the last line of the display shall display some portion of the last line of the edit buffer.
Current line: If no lines from the previous display remain on the screen, set to the first line of the display; otherwise, set to (line + the number of new lines displayed on this screen).
Current column: Set to non-<blank>.

## Display Information

```
Synopsis: <control>-G
```

This command shall be equivalent to the ex file command.

## Move Cursor Backwards

Synopsis: [count] <control>-H [count] h the current erase character (see stty)

If there are no characters before the current character on the current line, it shall be an error. If there are less than count previous characters on the current line, count shall be adjusted to the number of previous characters on the line.
If used as a motion command:

1. The text region shall be from the character before the starting cursor up to and including the countth character before the starting cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to (column - the number of columns occupied by count characters ending with the previous current column).

```
Move Down
Synopsis: [count] <newline>
    [count] <control>-J
    [count] <control>-M
    [count]<control>-N
    [count] i
    [count] <carriage-return>
    [count] +
```

If there are less than count lines after the current line in the edit buffer, it shall be an error.
If used as a motion command:

1. The text region shall include the starting line and the next count - 1 lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
Current line: Set to current line+ count.
Current column: Set to non-<blank> for the <carriage-return>, <control>-M, and + commands; otherwise, unchanged.

## Clear and Redisplay

```
Synopsis: <control>-L
If in open mode, clear the screen and redisplay the current line. Otherwise, clear and redisplay the screen.
Current line: Unchanged.
Current column: Unchanged.
Move Up
Synopsis: [count] <control>-P
[count] k
[count] -
If there are less than count lines before the current line in the edit buffer, it shall be an error.
If used as a motion command:
1. The text region shall include the starting line and the previous count lines.
2. Any text copied to a buffer shall be in line mode.
If not used as a motion command:
Current line: Set to current line - count.
Current column: Set to non-<blank> for the-command; otherwise, unchanged.
```

## Redraw Screen

```
Synopsis: <control>-R
If any lines have been deleted from the display screen and flagged as deleted on the terminal using the @ convention (see the beginning of the EXTENDED DESCRIPTION section), they shall be redisplayed to match the contents of the edit buffer.
It is unspecified whether lines flagged with @ because they do not fit on the terminal display shall be affected.
Current line: Unchanged.
Current column: Unchanged.
Scroll Backward
Synopsis: [count] <control>-U
If the current line is the first line of the edit buffer, it shall be an error.
If no count is specified, count shall default to the count associated with the previous <control>-D or <control>-U command. If there was no previous <control>-D or <control>-U command, count shall default to the value of the scroll edit option.
Current line: If count is greater than the current line, set to 1 ; otherwise, set to the current line count.
Current column: Set to non-<blank>.
```

## Scroll Backward by Line

Synopsis: [count] <control>-Y
Display the line count lines before the first line currently displayed.
If the current line is the first line of the edit buffer, it shall be an error. If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.

Current line: Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.

Current column: Unchanged.

## Edit the Alternate File

Synopsis: <control>-^
This command shall be equivalent to the $e x$ edit command, with the alternate pathname as its argument.

## Terminate Command or Input Mode

Synopsis: <ESC>
If a partial $v i$ command (as defined by at least one, non-count character) has been entered, discard the count and the command character(s).
Otherwise, if no command characters have been entered, and the <ESC> was the result of a map expansion, the terminal shall be alerted and the $<$ ESC $>$ character shall be discarded, but it shall not be an error.
Otherwise, it shall be an error.
Current line: Unchanged.
Current column: Unchanged.

## Search for tagstring

Synopsis: <control>-]
If the current character is not a word or <blank>, it shall be an error.
This command shall be equivalent to the extag command, with the argument to that command defined as follows.
If the current character is a <blank>:

1. Skip all <blank>s after the cursor up to the end of the line.
2. If the end of the line is reached, it shall be an error.

Then, the argument to the ex tag command shall be the current character and all subsequent characters, up to the first non-word character or the end of the line.

## Move Cursor Forward <br> Synopsis: [count] <space> [count] l (ell)

If there are less than count non-<newline>s after the cursor on the current line, count shall be adjusted to the number of non-<newline>s after the cursor on the line.
If used as a motion command:

1. If the current or countth character after the cursor is the last non-<newline> in the line, the text region shall be comprised of the current character up to and including the last non-<newline> in the line. Otherwise, the text region shall be from the current character up to, but not including, the countth character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
If there are no non-<newline>s after the current character on the current line, it shall be an error.

## Current line: Unchanged.

Current column: Set to the last column that displays any portion of the countth character after the current character.

## Replace Text with Results from Shell Command

Synopsis: [count] ! motion shell-commands <newline>
If the motion command is the! command repeated:

1. If the edit buffer is empty and no count was supplied, the command shall be the equivalent of the ex :read! command, with the text input, and no text shall be copied to any buffer.
2. Otherwise:
a. If there are less than count -1 lines after the current line in the edit buffer, it shall be an error.
b. The text region shall be from the current line up to and including the next count -1 lines.

Otherwise, the text region shall be the lines in which any character of the text region specified by the motion command appear.
Any text copied to a buffer shall be in line mode.
This command shall be equivalent to the ex! command for the specified lines.
Move Cursor to End-of-Line
Synopsis: [count] \$
It shall be an error if there are less than (count -1 ) lines after the current line in the edit buffer.
If used as a motion command:

1. If count is 1 :
a. It shall be an error if the line is empty.
b. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line, inclusive, and any text copied to a buffer shall be in character mode.
2. Otherwise, if the starting cursor position is at or before the first non-<blank> in the line, the text region shall consist of the current and the next count -1 lines, and any text saved to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line that is count -1 lines forward from the current line, and any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Set to the current line + count -1 .
Current column: The current column is set to the last display line column of the last non-<newline> in the line, or column position 1 if the line is empty.
The current column shall be adjusted to be on the last display line column of the last non-<newline> of the current line as subsequent commands change the current line, until a command changes the current column.

## Move to Matching Character

Synopsis: \%
If the character at the current position is not a parenthesis, bracket, or curly brace, search forward in the line to the first one of those characters. If no such character is found, it shall be an error.
The matching character shall be the parenthesis, bracket, or curly brace matching the parenthesis, bracket, or curly brace, respectively, that was at the current position or that was found on the current line.
Matching shall be determined as follows, for an open parenthesis:

1. Set a counter to 1 .
2. Search forwards until a parenthesis is found or the end of the edit buffer is reached.
3. If the end of the edit buffer is reached, it shall be an error.
4. If an open parenthesis is found, increment the counter by 1.
5. If a close parenthesis is found, decrement the counter by 1 .
6. If the counter is zero, the current character is the matching character.

Matching for a close parenthesis shall be equivalent, except that the search shall be backwards, from the starting character to the beginning of the buffer, a c
the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of the starting character to the matching character, inclusive, and any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Set to the line where the matching character is located.
Current column: Set to the last column where any portion of the matching character is displayed.

## Repeat Substitution

Synopsis: \&
Repeat the previous substitution command. This command shall be equivalent to the ex \& command with the current line as its addresses, and without options, count, or flags.

## Return to Previous Context at Beginning of Line

Synopsis: , character
It shall be an error if there is no line in the edit buffer marked by character.
If used as a motion command:

1. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
2. The text region shall consist of the starting line up to and including the marked line, and any text copied to a buffer shall be in line mode.
If not used as a motion command:
Current line: Set to the line referenced by the mark.
Current column: Set to non-<blank>.

## Return to Previous Context

Synopsis: character
It shall be an error if the marked line is no longer in the edit buffer. If the marked line no longer contains a character in the saved numbered character position, it shall be as if the marked position is the first non-<blank>.
If used as a motion command:

1. It shall be an error if the marked cursor references the same character in the edit buffer as the starting cursor.
2. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
3. If the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the marked cursor line is empty or the marked cursor references the first character of the marked cursor line, the text region shall consist of all lines containing characters from the starting cursor to the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in line mode.
4. Otherwise, if the marked cursor line is empty or the marked cursor references a character at or before the first non-<blank> non-<newline> of the marked cursor line, the region of text shall be from the starting cursor to the last non-<newline> of the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in character mode.
5. Otherwise, the region of text shall be from the starting cursor (inclusive), to the marked cursor (exclusive), and any text copied to a buffer shall be in character mode.
If not used as a motion command:
Current line: Set to the line referenced by the mark.
Current column: Set to the last column in which any portion of the character referenced by the mark is displayed.

## Return to Previous Section

Synopsis: [count] [ [
Move the cursor backward through the edit buffer to the first character of the previous section boundary, count times.
If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the countth next boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the last line of the edit buffer or the last non-<newline> of the last line of the edit buffer, the text region shall consist of the last character in the edit buffer up to and including the starting character, and any text saved to a buffer shall be in character mode.
3. Otherwise, the text region shall consist of the starting character up to but not including the first character in the countth next boundary, and any text copied to a buffer shall be in character mode.
If not used as a motion command:
Current line: Set to the line where the countth next boundary in the edit buffer starts.
Current column: Set to the last column in which any portion of the first character of the countth next boundary is displayed, or column position 1 if the line is empty.

Move to Next Section
Synopsis: [count] ]]
Move the cursor forward through the edit buffer to the first character of the next section boundary, count times.
If used as a motion command:

1. If the starting cursor was at the first character of the starting line or the starting line was empty, and the first character of the boundary was the first character of the boundary line, the text region shall consist of the current line up to and including the line where the countth previous boundary starts, and any text copied to a buffer shall be in line mode.
2. If the boundary was the first line of the edit buffer, the text region shall consist of the first character in the edit buffer up to but not including the starting character, and any text copied to a buffer shall be in character mode.
3. Otherwise, the text region shall consist of the first character in the countth previous section boundary up to but not including the starting character, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line where the countth previous boundary in the edit buffer starts.
Current column: Set to the last column in which any portion of the first character of the countth previous boundary is displayed, or column position 1 if the line is empty.

## Move to First Non-<blank> Position on Current Line

Synopsis:
If used as a motion command:

1. If the line has no non-<blank> non-<newline>s, or if the cursor is at the first non-<blank> non-<newline> of the line, it shall be an error.
2. If the cursor is before the first non-<blank> non-<newline> of the line, the text region shall be comprised of the current character, up to, but not including, the first non-<blank> non-<newline> of the line.
3. If the cursor is after the first non-<blank> non-<newline> of the line, the text region shall be from the character before the starting cursor up to and including the first non-<blank> non-<newline> of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to non-<blank>.

## Current and Line Above

Synopsis: [count] _
If there are less than count -1 lines after the current line in the edit buffer, it shall be an error.
If used as a motion command:

1. If count is less than 2, the text region shall be the current line.
2. Otherwise, the text region shall include the starting line and the next count -1 lines.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
Current line: Set to current line + count -1 .
Current column: Set to non-<blank>.
Move Back to Beginning of Sentence
Synopsis: [count] (
Move backward to the beginning of a sentence. This command shall be equivalent to the [I command, with the exception that sentence boundaries shall be used instead of section boundaries.

## Move Forward to Beginning of Sentence

Synopsis: [count] )
Move forward to the beginning of a sentence. This command shall be equivalent to the l] command, with the exception that sentence boundaries shall be used instead of section boundaries.

## Move Back to Preceding Paragraph

Synopsis: [count] \{
Move back to the beginning of the preceding paragraph. This command shall be equivalent to the [[ command, with the exception that paragraph boundaries shall be used instead of section boundaries.

## Move Forward to Next Paragraph

Synopsis: [count] \}
Move forward to the beginning of the next paragraph. This command shall be equivalent to the l] command, with the exception that paragraph boundaries shall be used instead of section boundaries.

## Move to Specific Column Position <br> Synopsis: [count] |

For the purposes of this command, lines that are too long for the current display and that have been folded shall be treated as having a single, 1 -based, number of columns.
If there are less than count columns in which characters from the current line are displayed on the screen, count shall be adjusted to be the last column in which any portion of the line is displayed on the screen.
If used as a motion command:

1. If the line is empty, or the cursor character is the same as the character on the countth column of the line, it shall be an error.
2. If the cursor is before the countth column of the line, the text region shall be comprised of the current character, up to but not including the character on the countth column of the line.
3. If the cursor is after the countth column of the line, the text region shall be from the character before the starting cursor up to and including the character on the countth column of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to the last column in which any portion of the character that is displayed in the count column of the line is displayed.

## Reverse Find Character

Synopsis: [count] ,
If the last $\mathbf{F}, \mathbf{f}, \mathbf{T}$, or $\mathbf{t}$ command was $\mathbf{F}, \mathbf{f}, \mathbf{T}$, or $\mathbf{t}$, this command shall be equivalent to an $\mathbf{f}, \mathbf{F}, \mathbf{t}$, or $\mathbf{T}$ command, respectively, with the specified count and the same search character.
If there was no previous $\mathbf{F}, \mathbf{f}, \mathbf{T}$, or $\mathbf{t}$ command, it shall be an error.

## Repeat

Synopsis: [count] .
Repeat the last !, <, >, A, C, D, I, J, O, P, R, S, X, Y, a, $\mathbf{c}, \mathbf{d}, \mathbf{i}, \mathbf{o}, \mathbf{p}, \mathbf{r}, \mathbf{s}, \mathbf{x}, \mathbf{y}$, or $\sim$ command. It shall be an error if none of these commands have been executed. Commands (other than commands that enter text input mode) executed as a result of map expansions, shall not change the value of the last repeatable command.
Repeated commands with associated motion commands shall repeat the motion command as well; however, any specified count shall replace the count(s) that were originally specified to the repeated command or its associated motion command.
If the motion component of the repeated command is $\mathbf{f}, \mathbf{F}, \mathbf{t}$, or $\mathbf{T}$, the repeated command shall not set the remembered search character for the ; and, commands.

If the repeated command is $\mathbf{p}$ or $\mathbf{P}$, and the buffer associated with that command was a numeric buffer named with a number less than 9 , the buffer associated with the repeated command shall be set to be the buffer named by the name of the previous buffer logically incremented by 1 .
If the repeated character is a text input command, the input text associated with that command is repeated literally:

- Input characters are neither macro or abbreviation-expanded.
- Input characters are not interpreted in any special way with the exception that <newline>, <carriage-return>, and <control>-T behave as described in Input Mode Commands in vi (on page 1026).
Current line: Set as described for the repeated command.
Current column: Set as described for the repeated command.
Find Regular Expression
Synopsis:
If the input line contains no non-<newline>s, it shall be equivalent to a line containing only the last regular expression encountered. The enhanced regular expressions supported by vi are described in Regular Expressions in ex (on page 392).
Otherwise, the line shall be interpreted as one or more regular expressions, optionally followed by an address offset or a $v i \mathbf{z}$ command.
If the regular expression is not the last regular expression on the line, or if a line offset or $\mathbf{z}$ command is specified, the regular expression shall be terminated by an unescaped '/' character, which shall not be used as part of the regular expression. If the regular expression is not the first regular expression on the line, it shall be preceded by zero or more <blank>s, a semicolon, zero or more <blank>s, and a leading '/' character, which shall not be interpreted as part of the regular expression. It shall be an error to precede any regular expression with any characters other than these.
Each search shall begin from the character after the first character of the last match (or, if it is the first search, after the cursor). If the wrapscan edit option is set, the search shall continue to the
character before the starting cursor character; otherwise, to the end of the edit buffer. It shall be an error if any search fails to find a match, and an informational message to this effect shall be displayed.
An optional address offset (see Addressing in ex (on page 363)) can be specified after the last regular expression by including a trailing '/' character after the regular expression and specifying the address offset. This offset will be from the line containing the match for the last regular expression specified. It shall be an error if the line offset would indicate a line address less than 1 or greater than the last line in the edit buffer. An address offset of zero shall be supported. It shall be an error to follow the address offset with any other characters than <blank>s.

If not used as a motion command, an optional $\mathbf{z}$ command (see Redraw Window (on page 1025)) can be specified after the last regular expression by including a trailing '/' character after the regular expression, zero or more <blank>s, $a^{\prime} z^{\prime}$, zero or more <blank>s, an optional new window edit option value, zero or more <blank>s, and a location character. The effect shall be as if the $\mathbf{z}$ command was executed after the / command. It shall be an error to follow the $\mathbf{z}$ command with any other characters than <blank>s.

The remembered search direction shall be set to forward.
If used as a motion command:

1. It shall be an error if the last match references the same character in the edit buffer as the starting cursor.
2. If any address offset is specified, the last match shall be adjusted by the specified offset as described previously.
3. If the starting cursor is after the last match, then the locations of the starting cursor and the last match in the edit buffer shall be logically swapped.
4. If any address offset is specified, the text region shall consist of all lines containing characters from the starting cursor to the last match line, inclusive, and any text copied to a buffer shall be in line mode.
5. Otherwise, if the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the last match line is empty or the last match starts at the first character of the last match line, the text region shall consist of all lines containing characters from the starting cursor to the line before the last match line, inclusive, and any text copied to a buffer shall be in line mode.
6. Otherwise, if the last match line is empty or the last match begins at a character at or before the first non-<blank> non-<newline> of the last match line, the region of text shall be from the current cursor to the last non-<newline> of the line before the last match line, inclusive, and any text copied to a buffer shall be in character mode.
7. Otherwise, the region of text shall be from the current cursor (inclusive), to the first character of the last match (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: If a match is found, set to the last matched line plus the address offset, if any; otherwise, unchanged.

Current column: Set to the last column on which any portion of the first character in the last matched string is displayed, if a match is found; otherwise, unchanged.

## Move to First Character in Line

## Synopsis: 0 (zero)

Move to the first character on the current line. The character

specified by the motion command.
Current column: Set to non-<blank>.

## Shift Right

Synopsis: [count] > motion
If the motion command is the > command repeated:

1. If there are less than count -1 lines after the current line in the edit buffer, it shall be an error.
2. The text region shall be from the current line, up to and including the next count -1 lines.

Shift any line with characters in the text region specified by the count and motion command one shiftwidth (see the ex shiftwidth option) away from the start of the line, as described by the ex> command. The unshifted lines shall be copied into the unnamed buffer in line mode.
Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.
Current column: Set to non-<blank>.

## Scan Backwards for Regular Expression

Synopsis: ?
Scan backwards; the ? command shall be equivalent to the $\$ command (see Find Regular Expression (on page 1009)) with the following exceptions:

1. The input prompt shall be a ? ?
2. Each search shall begin from the character before the first character of the last match (or, if it is the first search, the character before the cursor character).
3. The search direction shall be from the cursor toward the beginning of the edit buffer, and the wrapscan edit option shall affect whether the search wraps to the end of the edit buffer and continues.
4. The remembered search direction shall be set to backward.

## Execute

Synopsis:
@buffer
If the buffer is specified as @, the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.
Behave as if the contents of the named buffer were entered as standard input. After each line of a line-mode buffer, and all but the last line of a character mode buffer, behave as if a <newline> were entered as standard input.
If an error occurs during this process, an error message shall be written, and no more characters resulting from the execution of this command shall be processed.
If a count is specified, behave as if that count were entered as user input before the characters from the @ buffer were entered.
Current line: As specified for the individual commands.
Current column: As specified for the individual commands.

## Reverse Case

Synopsis: [count] ~
Reverse the case of the current character and the next count -1 characters, such that lowercase characters that have uppercase counterparts shall be changed to uppercase characters, and uppercase characters that have lowercase counterparts shall be changed to lowercase characters, as prescribed by the current locale. No other characters shall be affected by this command.
If there are less than count -1 characters after the cursor in the edit buffer, count shall be adjusted to the number of characters after the cursor in the edit buffer minus 1 .
For the purposes of this command, the next character after the last non-<newline> on the line shall be the next character in the edit buffer.
Current line: Set to the line including the (count-1)th character after the cursor.
Current column: Set to the last column in which any portion of the (count-1)th character after the cursor is displayed.

## Append

Synopsis: [count] a
Enter text input mode after the current cursor position. No characters already in the edit buffer shall be affected by this command. A count shall cause the input text to be appended count -1 more times to the end of the input.
Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1026)).

## Append at End-of-Line

Synopsis: [count] A
This command shall be equivalent to the vi command:
\$ [count ] a
(see Append (on page 1013)).

## Move Backward to Preceding Word

## Synopsis: [count] b

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the $\mathbf{B}$ command.

## Move Backward to Preceding Bigword

Synopsis: [count] B
If the edit buffer is empty or the cursor is on the first character of the edit buffer, it shall be an error. If less than count bigwords begin between the cursor and the start of the edit buffer, count shall be adjusted to the number of bigword beginnings between the cursor and the start of the edit buffer.

If used as a motion command:

1. The text region shall be from the first character of the countth previous bigword beginning up to but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

Current line: Set to the line containing the current column.
Current column: Set to the last column upon which any part of the first character of the countth previous bigword is displayed.

## Change

Synopsis: [buffer][count] c motion
If the motion command is the command repeated:

1. The buffer text shall be in line mode.
2. If there are less than count -1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next count -1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.
The replaced text shall be copied into buffer, if specified, and into the unnamed buffer. If the text to be replaced contains characters from more than a single line, or the buffer text is in line mode, the replaced text shall be copied into the numeric buffers as well.

If the buffer text is in line mode:

1. Any lines that contain characters in the region shall be deleted, and the editor shall enter text input mode at the beginning of a new line which shall replace the first line deleted.
2. If the autoindent edit option is set, autoindent characters equal to the autoindent characters on the first line deleted shall be inserted as if entered by the user.
Otherwise, if characters from more than one line are in the region of text:
3. The text shall be deleted.
4. Any text remaining in the last line in the text region shall be appended to the first line in the region, and the last line in the region shall be deleted.
5. The editor shall enter text input mode after the last character not deleted from the first line in the text region, if any; otherwise, on the first column of the first line in the region.

Otherwise:

1. If the glyph for ${ }^{\prime} \$^{\prime}$ is smaller than the region, the end of the region shall be marked with $a^{\prime}$ \$'
2. The editor shall enter text input mode, overwriting the region of text.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1026)).

## Change to End-of-Line

Synopsis: [buffer][count] C
This command shall be equivalent to the vi command:
[buffer] [count] C\$
See the c command.

## Delete

Synopsis: [buffer][count] d motion
If the motion command is the $\mathbf{d}$ command repeated:

1. The buffer text shall be in line mode.
2. If there are less than count -1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next count -1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.
If in open mode, and the current line is deleted, and the line remains on the display, an ' @' character shall be displayed as the first glyph of that line.
Delete the region of text into buffer, if specified, and into the unnamed buffer. If the text to be deleted contains characters from more than a single line, or the buffer text is in line mode, the deleted text shall be copied into the numeric buffers, as well.

Current line: Set to the first text region line that appears in the edit buffer, unless that line has been deleted, in which case it shall be set to the last line in the edit buffer, or line 1 if the edit buffer is empty.

## Current column:

1. If the line is empty, set to column position 1.
2. Otherwise, if the buffer text is in line mode or the motion was from the cursor toward the end of the edit buffer:
a. If a character from the current line is displayed in the current column, set to the last column that displays any portion of that character.
b. Otherwise, set to the last column in which any portion of any character in the line is displayed.
3. Otherwise, if a character is displayed in the column that began the text region, set to the last column that displays any portion of that character.
4. Otherwise, set to the last column in which any portion of any character in the line is displayed.

## Delete to End-of-Line

Synopsis: [buffer] D
Delete the text from the current position to the end of the current line; equivalent to the vi command:
[buffer] d\$

## Move to End-of-Word

Synopsis: [count] e
With the exception that words are used instead of bigwords as the delimiter, this command shall be equivalent to the E command.

## Move to End-of-Bigword

Synopsis: [count] E
If the edit buffer is empty it shall be an error. If less than count bigwords end between the cursor and the end of the edit buffer, count shall be adjusted to the number of bigword endings between the cursor and the end of the edit buffer.

If used as a motion command:

1. The text region shall be from the last character of the countth next bigword up to and including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Set to the line containing the current column.
Current column: Set to the last column upon which any part of the last character of the countth next bigword is displayed.

## Find Character in Current Line (Forward)

Synopsis: [count] f character
It shall be an error if count occurrences of the character do not occur after the cursor in the line.
If used as a motion command:

1. The text range shall be from the cursor character up to and including the countth occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to the last column in which any portion of the countth occurrence of the specified character after the cursor appears in the line.

## Find Character in Current Line (Reverse)

```
Synopsis: [count] F character
```

It shall be an error if count occurrences of the character do not occur before the cursor in the line.
If used as a motion command:

1. The text region shall be from the countth occurrence of the specified character before the cursor, up to, but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to the last column in which any portion of the countth occurrence of the specified character before the cursor appears in the line.

## Move to Line <br> Synopsis: [count] G

If count is not specified, it shall default to the last line of the edit buffer. If count is greater than the last line of the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall be from the cursor line up to and including the specified line.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
Current line: Set to count if count is specified; otherwise, the last line.
Current column: Set to non-<blank>.

## Move to Top of Screen

Synopsis: [count] H
If the beginning of the line count greater than the first line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall be from the starting line up to and including (the first line of the display + count -1 ).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
If in open mode, this command shall set the current column to non-<blank> and do nothing else.
Otherwise, it shall set the current line and current column as follows.
Current line: Set to (the first line of the display + count -1 ).
Current column: Set to non-<blank>.

## Insert Before Cursor

Synopsis: [count] i
Enter text input mode before the current cursor position. No characters already in the edit buffer shall be affected by this command. A count shall cause the input text to be appended count -1 more times to the end of the input.
Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1026)).

## Insert at Beginning of Line

Synopsis: [count] I
This command shall be equivalent to the $v i$ command ${ }^{\wedge}[$ count $] \mathbf{i}$.

## Join <br> Synopsis: [count] J

If the current line is the last line in the edit buffer, it shall be an error.
This command shall be equivalent to the $e x$ join command with no addresses, and an $e x$ command count value of 1 if count was not specified or if a count of 1 was specified, and an ex command count value of count -1 for any other value of count, except that the current line and column shall be set as follows.

## Current line: Unchanged.

Current column: The last column in which any portion of the character following the last character in the initial line is displayed, or the last non-<newline> in the line if no characters were appended.

## Move to Bottom of Screen

Synopsis: [count] L
If the beginning of the line count less than the last line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall include all lines from the starting cursor line to (the last line of the display $-($ count -1$)$ ).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

1. If in open mode, this command shall set the current column to non-<blank> and do nothing else.
2. Otherwise, it shall set the current line and current column as follows.

Current line: Set to (the last line of the display -(count -1 )).
Current column: Set to non-<blank>.

## Mark Position

Synopsis: m letter
This command shall be equivalent to the ex mark command with the specified character as an argument.

## Move to Middle of Screen

Synopsis: M
The middle line of the display shall be calculated as follows:

```
(the top line of the display) + (((number of lines displayed) +1) /2) -1
```

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall include all lines from the starting cursor line up to and including the middle line of the display.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:
If in open mode, this command shall set the current column to non-<blank> and do nothing else.
Otherwise, it shall set the current line and current column as follows.
Current line: Set to the middle line of the display.
Current column: Set to non-<blank>.

## Repeat Regular Expression Find (Forward)

Synopsis: n
If the remembered search direction was forward, the $\mathbf{n}$ command shall be equivalent to the vi / command with no characters entered by the user. Otherwise, it shall be equivalent to the vi ? command with no characters entered by the user.
If the $\mathbf{n}$ command is used as a motion command for the ! command, the editor shall not enter text input mode on the last line on the screen, and shall behave as if the user entered a single '!' character as the text input.

## Repeat Regular Expression Find (Reverse)

Synopsis: N
Scan for the next match of the last pattern given to / or ?, but in the reverse direction; this is the reverse of $\mathbf{n}$.

If the remembered search direction was forward, the $\mathbf{N}$ command shall be equivalent to the $v i$ ? command with no characters entered by the user. Otherwise, it shall be equivalent to the vi / command with no characters entered by the user. If the $\mathbf{N}$ command is used as a motion command for the! command, the editor shall not enter text input mode on the last line on the screen, and shall behave as if the user entered a single! character as the text input.

## Insert Empty Line Below

Synopsis:
Enter text input mode in a new line appended after the current line. A count shall cause the input text to be appended count -1 more times to the end of the already added text, each time starting on a new, appended line.
Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1026)).

Insert Empty Line Above
Synopsis:
Enter text input mode in a new line inserted before the current line. A count shall cause the input text to be appended count -1 more times to the end of the already added text, each time starting on a new, appended line.

Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1026)).

## Put from Buffer Following

Synopsis: [buffer] p
If no buffer is specified, the unnamed buffer shall be used.
If the buffer text is in line mode, the text shall be appended below the current line, and each line of the buffer shall become a new line in the edit buffer. A count shall cause the buffer text to be appended count -1 more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be appended into the current line after the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A count shall cause the buffer text to be appended count -1 more times to the end of the already added text, each time starting after the last added character.
Current line: If the buffer text is in line mode, set the line to line +1 ; otherwise, unchanged.
Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of the first non-<blank> in the line is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline $>$ in the first line of the buffer is displayed.
If the buffer text is in character mode:
3. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
4. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
5. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

## Put from Buffer Before

Synopsis: [buffer] P
If no buffer is specified, the unnamed buffer shall be used.
If the buffer text is in line mode, the text shall be inserted above the current line, and each line of the buffer shall become a new line in the edit buffer. A count shall cause the buffer text to be appended count -1 more times to the end of the already added text, each time starting on a new, appended line.
If the buffer text is in character mode, the text shall be inserted into the current line before the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A count shall cause the buffer text to be appended count -1 more times to the end of the already added text, each time starting after the last added character.

## Current line: Unchanged.

Current column: If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of that character is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.
If the buffer text is in character mode:
3. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
4. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
5. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

## Enter ex Mode

Synopsis: Q
Leave visual or open mode and enter ex command mode.
Current line: Unchanged.
Current column: Unchanged.

## Replace Character

Synopsis: [count] r character
Replace the count characters at and after the cursor with the specified character. If there are less than count non-<newline>s at and after the cursor on the line, it shall be an error.

If character is <control>-V, any next character other than the <newline> shall be stripped of any special meaning and used as a literal character.

If character is $\langle\mathrm{ESC}\rangle$, no replacement shall be made and the current line and current column shall be unchanged.
If character is <carriage-return> or <newline>, count new lines shall be appended to the current line. All but the last of these lines shall be empty. count characters at and after the cursor shall be discarded, and any remaining characters after the cursor in the current line shall be moved to the last of the new lines. If the autoindent edit option is set, they shall be preceded by the same number of autoindent characters found on the line from which the command was executed.

Current line: Unchanged unless the replacement character is a <carriage-return> or <newline>, in which case it shall be set to line + count.

Current column: Set to the last column position on which a portion of the last replaced character is displayed, or if the replacement character caused new lines to be created, set to non-<blank>.

## Replace Characters

Synopsis: $\quad \mathrm{R}$
Enter text input mode at the current cursor position possibly replacing text on the current line. A count shall cause the input text to be appended count -1 more times to the end of the input.
Current line/column: As specified for the text input commands (see Input Mode Commands in vi (on page 1026)).

Substitute Character
Synopsis: [buffer][count] s
This command shall be equivalent to the vi command:
[buffer][count] c<space>

## Substitute Lines

Synopsis: [buffer][count] S
This command shall be equivalent to the vi command:
[buffer][count] c_

## Move Cursor to Before Character (Forward)

Synopsis: [count] t character
It shall be an error if count occurrences of the character do not occur after the cursor in the line.
If used as a motion command:

1. The text region shall be from the cursor up to but not including the counth occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to the last column in which any portion of the character before the countth occurrence of the specified character after the cursor appears in the line.

## Move Cursor to After Character (Reverse) <br> Synopsis: [count] T character

It shall be an error if count occurrences of the character do not occur before the cursor in the line.
If used as a motion command:

1. If the character before the cursor is the specified character, it shall be an error.
2. The text region shall be from the character before the cursor up to but not including the countth occurrence of the specified character before the cursor.
3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:
Current line: Unchanged.
Current column: Set to the last column in which any portion of the character after the countth occurrence of the specified character before the cursor appears in the line.

Undo
Synopsis: u
This command shall be equivalent to the ex undo command except that the current line and current column shall be set as follows:

Current line: Set to the first line added or changed if any; otherwise, move to the line preceding any deleted text if one exists; otherwise, move to line 1.

Current column: If undoing an ex command, set to the first non-<blank>.
Otherwise, if undoing a text input command:

1. If the command was a $\mathbf{C}, \mathbf{c}, \mathbf{O}, \mathbf{o}, \mathbf{R}, \mathbf{S}$, or $\mathbf{s}$ command, the current column shall be set to the value it held when the text input command was entered.
2. Otherwise, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline>s follow the text deleted from this line, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, if a single line was modified (that is, not added or deleted) by the $\mathbf{u}$ command:

1. If text was added or changed, set to the last column in which any portion of the first character added or changed is displayed.
2. If text was deleted, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline>s follow the deleted text, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.
Otherwise, set to non-<blank>.
Undo Current Line
Synopsis: U
Restore the current line to its state immediately before the most recent time that it became the current line.

Current line: Unchanged.
Current column: Set to the first column in the line in which any portion of the first character in the line is displayed.

Move to Beginning of Word
Synopsis: [count] w
With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the $\mathbf{W}$ command.

## Move to Beginning of Bigword

Synopsis: [count] W
If the edit buffer is empty, it shall be an error. If there are less than count bigwords between the cursor and the end of the edit buffer, count shall be adjusted to move the cursor to the last bigword in the edit buffer.
If used as a motion command:

1. If the associated command is $\mathbf{c}$, count is 1 , and the cursor is on a <blank>, the region of text shall be the current character and no further action shall be taken.
2. If there are less than count bigwords between the cursor and the end of the edit buffer, then the command shall succeed, and the region of text shall include the last character of the edit buffer.
3. If there are <blank>s or an end-of-line that precede the countth bigword, and the associated command is $\mathbf{c}$, the region of text shall be up to and including the last character before the preceding <blank>s or end-of-line.
4. If there are <blank>s or an end-of-line that precede the bigword, and the associated command is $\mathbf{d}$ or $\mathbf{y}$, the region of text shall be up to and including the last <blank> before the start of the bigword or end-of-line.
5. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

1. If the cursor is on the last character of the edit buffer, it shall be an error.

Current line: Set to the line containing the current column.
Current column: Set to the last column in which any part of the first character of the countth next bigword is displayed.

## Delete Character at Cursor

Synopsis: [buffer][count] x
Delete the count characters at and after the current character into buffer, if specified, and into the unnamed buffer.

If the line is empty, it shall be an error. If there are less than count non-<newline>s at and after the cursor on the current line, count shall be adjusted to the number of non-<newline>s at and after the cursor.

Current line: Unchanged.
Current column: If the line is empty, set to column position 1. Otherwise, if there were count or less non-<newline>s at and after the cursor on the current line, set to the last column that displays any part of the last non-<newline> of the line. Otherwise, unchanged.

## Delete Character Before Cursor

Synopsis: [buffer][count] X
Delete the count characters before the current character into buffer, if specified, and into the unnamed buffer.

If there are no characters before the current character on the current line, it shall be an error. If there are less than count previous characters on the current line, count shall be adjusted to the number of previous characters on the line.

Current line: Unchanged.
Current column: Set to (current column - the width of the deleted characters).

Yank
Synopsis: [buffer][count] y motion
Copy (yank) the region of text into buffer, if specified, and into the unnamed buffer.
If the motion command is the $\mathbf{y}$ command repeated:

1. The buffer shall be in line mode.
2. If there are less than count -1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next count -1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.
Current line: If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

## Current column:

1. If the motion was from the current cursor position toward the end of the edit buffer, unchanged.
2. Otherwise, if the current line is empty, set to column position 1.
3. Otherwise, set to the last column that displays any part of the first character in the file that is part of the text region specified by the motion command.

## Yank Current Line

Synopsis: [buffer][count] $Y$
This command shall be equivalent to the vi command:

## Redraw Window

If in open mode, the $\mathbf{z}$ command shall have the Synopsis;
Synopsis: [count] z
If count is not specified, it shall default to the window edit option -1 . The $\mathbf{z}$ command shall be equivalent to the ex z command, with a type character of = and a count of count -2 , except that the current line and current column shall be set as follows, and the window edit option shall not be affected. If the calculation for the count argument would result in a negative number, the count argument to the $e x z$ command shall be zero. A blank line shall be written after the last line is written.

```
Current line: Unchanged.
Current column: Unchanged.
If not in open mode, the \(\mathbf{z}\) command shall have the following Synopsis:
Synopsis: [line] z [count] character
```

If line is not specified, it shall default to the current line. If line is specified, but is greater than the number of lines in the edit buffer, it shall default to the number of lines in the edit buffer.
If count is specified, the value of the window edit option shall be set to count (as described in the ex window command), and the screen shall be redrawn.

line shall be placed as specified by the following characters:
<newline>, <carriage-return>
Place the beginning of the line on the first line of the display.
. Place the beginning of the line in the center of the display. The middle line of the display shall be calculated as described for the $\mathbf{M}$ command.

- Place an unspecified portion of the line on the last line of the display.
+ If line was specified, equivalent to the <newline> case. If line was not specified, display a screen where the first line of the display shall be (current last line) +1 . If there are no lines after the last line in the display, it shall be an error.
- If line was specified, display a screen where the last line of the display shall contain an unspecified portion of the first line of a display that had an unspecified portion of the specified line on the last line of the display. If this calculation results in a line before the beginning of the edit buffer, display the first screen of the edit buffer.
Otherwise, display a screen where the last line of the display shall contain an unspecified portion of (current first line -1 ). If this calculation results in a line before the beginning of the edit buffer, it shall be an error.

Current line: If line and the ${ }^{\prime}{ }^{\wedge}$ ' character were specified:

1. If the first screen was displayed as a result of the command attempting to display lines before the beginning of the edit buffer: if the first screen was already displayed, unchanged; otherwise, set to (current first line -1).
2. Otherwise, set to the last line of the display.

If line and the ${ }^{\prime}+{ }^{\prime}$ character were specified, set to the first line of the display.
Otherwise, if line was specified, set to line.
Otherwise, unchanged.
Current column: Set to non-<blank>.

## Exit

Synopsis:

This command shall be equivalent to the ex xit command with no addresses, trailing !, or filename (see the ex xit command).

## Input Mode Commands in vi

In text input mode, the current line shall consist of zero or more of the following categories, plus the terminating <newline>:

1. Characters preceding the text input entry point

Characters in this category shall not be modified during text input mode.
2. autoindent characters
autoindent characters shall be automatically inserted into each line that is created in text input mode, either as a result of entering a <newline> or <carriage-return> while in text input mode, or as an effect of the command itself; for example, $\mathbf{O}$ or $\mathbf{o}$ (see the ex autoindent command), as if entered by the user.
It shall be possible to erase autoindent characters with the <control>-D command; it is unspecified whether they can be erased by <control>-H, <control>-U, and <control>-W characters. Erasing any autoindent character turns the glyph into erase-columns and
deletes the character from the edit buffer, but does not change its representation on the screen.
3. Text input characters

Text input characters are the characters entered by the user. Erasing any text input character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

Each text input character entered by the user (that does not have a special meaning) shall be treated as follows:
a. The text input character shall be appended to the last character in the edit buffer from the first, second, or third categories.
b. If there are no erase-columns on the screen, the text input command was the $\mathbf{R}$ command, and characters in the fifth category from the original line follow the cursor, the next such character shall be deleted from the edit buffer. If the slowopen edit option is not set, the corresponding glyph on the screen shall become erase-columns.
c. If there are erase-columns on the screen, as many columns as they occupy, or as are necessary, shall be overwritten to display the text input character. (If only part of a multi-column glyph is overwritten, the remainder shall be left on the screen, and continue to be treated as erase-columns; it is unspecified whether the remainder of the glyph is modified in any way.)
d. If additional display line columns are needed to display the text input character:

1. If the slowopen edit option is set, the text input characters shall be displayed on subsequent display line columns, overwriting any characters displayed in those columns.
2. Otherwise, any characters currently displayed on or after the column on the display line where the text input character is to be displayed shall be pushed ahead the number of display line columns necessary to display the rest of the text input character.
3. Erase-columns

Erase-columns are not logically part of the edit buffer, appearing only on the screen, and may be overwritten on the screen by subsequent text input characters. When text input mode ends, all erase-columns shall no longer appear on the screen.
Erase-columns are initially the region of text specified by the command (see Change (on page 1014)); however, erasing autoindent or text input characters causes the glyphs of the erased characters to be treated as erase-columns.
5. Characters following the text region for the command, or the text input entry point for all other commands

Characters in this category shall not be modified during text input mode, except as specified in category 3.b. for the $\mathbf{R}$ text input command, or as <blank>s deleted when a <newline> or <carriage-return> is entered.

It is unspecified whether it is an error to attempt to erase past the beginning of a line that was created by the entry of a <newline> or <carriage-return> during text input mode. If it is not an error, the editor shall behave as if the erasing character was entered immediately after the last text input character entered on the previous line, and all of the non-<newline>s on the current line shall be treated as erase-columns.
When text input mode is entered, or after a text input mode character is entered (except as
specified for the special characters below), the cursor shall be positioned as follows:

1. On the first column that displays any part of the first erase-column, if one exists
2. Otherwise, if the slowopen edit option is set, on the first display line column after the last character in the first, second, or third categories, if one exists
3. Otherwise, the first column that displays any part of the first character in the fifth category, if one exists
4. Otherwise, the display line column after the last character in the first, second, or third categories, if one exists
5. Otherwise, on column position 1

The characters that are updated on the screen during text input mode are unspecified, other than that the last text input character shall always be updated, and, if the slowopen edit option is not set, the current cursor character shall always be updated.
The following specifications are for command characters entered during text input mode.

## NUL

Synopsis: NUL
If the first character of the text input is a NUL, the most recently input text shall be input as if entered by the user, and then text input mode shall be exited. The text shall be input literally; that is, characters are neither macro or abbreviation expanded, nor are any characters interpreted in any special manner. It is unspecified whether implementations shall support more than 256 bytes of remembered input text.

## <control>-D <br> Synopsis: <control>-D

The <control>-D character shall have no special meaning when in text input mode for a lineoriented command (see Command Descriptions in vi (on page 994)).
This command need not be supported on block-mode terminals.
If the cursor does not follow an autoindent character, or an autoindent character and a' $0^{\prime}$ or ' ^ ' character:

1. If the cursor is in column position 1, the <control>-D character shall be discarded and no further action taken.
2. Otherwise, the <control>-D character shall have no special meaning.

If the last input character was $a^{\prime} 0^{\prime}$, the cursor shall be moved to column position 1.
Otherwise, if the last input character was a $\quad \wedge \prime$, the cursor shall be moved to column position 1. In addition, the autoindent level for the next input line shall be derived from the same line from which the autoindent level for the current input line was derived.

Otherwise, the cursor shall be moved back to the column after the previous shiftwidth (see the ex shiftwidth command) boundary.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 1026).
Current line: Unchanged.
Current column: Set to 1 if the <control>-D was preceded by a ' ${ }^{\prime \prime}$ or ${ }^{\prime} 0^{\prime}$; otherwise, set to (column -1 ) -((column -2) \% shiftwidth).
<control>-H
Synopsis: <control>-H
If in text input mode for a line-oriented command, and there are no characters to erase, text input mode shall be terminated, no further action shall be done for this command, and the current line and column shall be unchanged.

If there are characters other than autoindent characters that have been input on the current line before the cursor, the cursor shall move back one character.

Otherwise, if there are autoindent characters on the current line before the cursor, it is implementation-defined whether the <control>-H command is an error or if the cursor moves back one autoindent character.
Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-H command is an error or if it is equivalent to entering <control>-H after the last input character on the previous input line.
Otherwise, it shall be an error.
All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 1026).

The current erase character (see stty) shall cause an equivalent action to the <control>-H command, unless the previously inserted character was a backslash, in which case it shall be as if the literal current erase character had been inserted instead of the backslash.
Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line -1 .

Current column: Set to the first column that displays any portion of the character backed up over.

If input was part of a line-oriented command, text input mode shall be terminated and the command shall continue execution with the input provided.
Otherwise, terminate the current line. If there are no characters other than autoindent characters on the line, all characters on the line shall be discarded. Otherwise, it is unspecified whether the autoindent characters in the line are modified by entering these characters.
Continue text input mode on a new line appended after the current line. If the slowopen edit option is set, the lines on the screen below the current line shall not be pushed down, but the first of them shall be cleared and shall appear to be overwritten. Otherwise, the lines of the screen below the current line shall be pushed down.

If the autoindent edit option is set, an appropriate number of autoindent characters shall be added as a prefix to the line as described by the ex autoindent edit option.
All columns after the cursor that are erase-columns (as described in Input Mode Commands in vi (on page 1026)) shall be discarded.
If the autoindent edit option is set, all <blank>s immediately following the cursor shall be discarded.

All remaining characters after the cursor shall be transferred to the new line, positioned after
any autoindent characters.
Current line: Set to current line +1 .
Current column: Set to the first column that displays any portion of the first character after the autoindent characters on the new line, if any, or the first column position after the last autoindent character, if any, or column position 1.

## <control>-T

Synopsis: <control>-T
The <control>-T character shall have no special meaning when in text input mode for a lineoriented command (see Command Descriptions in vi (on page 994)).
This command need not be supported on block-mode terminals.
Behave as if the user entered the minimum number of <blank>s necessary to move the cursor forward to the column position after the next shiftwidth (see the ex shiftwidth command) boundary.

## Current line: Unchanged.

Current column: Set to column + shiftwidth - ((column -1) \% shiftwidth).
<control>-U
Synopsis: <control>-U
If there are characters other than autoindent characters that have been input on the current line before the cursor, the cursor shall move to the first character input after the autoindent characters.
Otherwise, if there are autoindent characters on the current line before the cursor, it is implementation-defined whether the <control>-U command is an error or if the cursor moves to the first column position on the line.
Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-U command is an error or if it is equivalent to entering <control>- U after the last input character on the previous input line.

Otherwise, it shall be an error.
All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 1026).
The current kill character (see stty) shall cause an equivalent action to the <control>-U command, unless the previously inserted character was a backslash, in which case it shall be as if the literal current kill character had been inserted instead of the backslash.
Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line -1 .

Current column: Set to the first column that displays any portion of the last character backed up over.
$\begin{array}{ll}\text { <control>-V } & \\ \text { Synopsis: } & \begin{array}{l}\text { <control>-V } \\ \\ \\ \end{array} \text { <control>-Q }\end{array}$
Allow the entry of any subsequent character, other than <control>-J or the <newline>, as a literal character, removing any special meaning that it may have to the editor in text input mode. If a <control>-V or <control>-Q is entered before a <control>-J or <newline>, the <control>-V or <control>-Q character shall be discarded, and the <control>-J or <newline> shall behave as described in the <newline> command character during input mode.

For purposes of the display only, the editor shall behave as if a ${ }^{\prime}$ ^' character was entered, and the cursor shall be positioned as if overwriting the ${ }^{\wedge}{ }^{\wedge}$ character. When a subsequent character is entered, the editor shall behave as if that character was entered instead of the original <control>-V or <control>-Q character.
Current line: Unchanged.
Current column: Unchanged.

## <control>-W

Synopsis: <control>-W

If there are characters other than autoindent characters that have been input on the current line before the cursor, the cursor shall move back over the last word preceding the cursor (including any <blank>s between the end of the last word and the current cursor); the cursor shall not move to before the first character after the end of any autoindent characters.
Otherwise, if there are autoindent characters on the current line before the cursor, it is implementation-defined whether the <control>-W command is an error or if the cursor moves to the first column position on the line.
Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-W command is an error or if it is equivalent to entering <control>-W after the last input character on the previous input line.

Otherwise, it shall be an error.
All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in Input Mode Commands in vi (on page 1026).
Current line: Unchanged, unless previously input lines are erased, in which case it shall be set to line -1 .

Current column: Set to the first column that displays any portion of the last character backed up over.
<ESC>
Synopsis: <ESC>
If input was part of a line-oriented command:

1. If interrupt was entered, text input mode shall be terminated and the editor shall return to command mode. The terminal shall be alerted.
2. If <ESC> was entered, text input mode shall be terminated and the command shall continue execution with the input provided.
Otherwise, terminate text input mode and return to command mode.
Any autoindent characters entered on newly created lines that have no other non-<newline>s
shall be deleted.
Any leading autoindent and <blank>s on newly created lines shall be rewritten to be the minimum number of <blank>s possible.
The screen shall be redisplayed as necessary to match the contents of the edit buffer.
Current line: Unchanged.
Current column:
3. If there are text input characters on the current line, the column shall be set to the last column where any portion of the last text input character is displayed.
4. Otherwise, if a character is displayed in the current column, unchanged.
5. Otherwise, set to column position 1.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

When any error is encountered and the standard input is not a terminal device file, vi shall not write the file or return to command or text input mode, and shall terminate with a non-zero exit status.

Otherwise, when an unrecoverable error is encountered it shall be equivalent to a SIGHUP asynchronous event.
Otherwise, when an error is encountered, the editor shall behave as specified in Command Descriptions in ví (on page 994).

## APPLICATION USAGE

None.

## EXAMPLES

None.

## RATIONALE

See the RATIONALE for ex for more information on vi. Major portions of the vi utility specification point to $e x$ to avoid inadvertent divergence. While $e x$ and $v i$ have historically been implemented as a single utility, this is not required by IEEE Std 1003.1-200x.
It is recognized that portions of vi would be difficult, if not impossible, to implement satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing, thus it is not a mandatory requirement that such features should work on all terminals. It is the intention, however, that a vi implementation should provide the full set of capabilities on all terminals capable of supporting them.

Historically, vi exited immediately if the standard input was not a terminal. IEEE Std 1003.1-200x permits, but does not require, this behavior. An end-of-file condition is not equivalent to an end-of-file character. A common end-of-file character, <control>-D, is historically a vi command.

The text in the STDOUT section reflects the usage of the verb display in this section; some implementations of vi use standard output to write to the terminal, but IEEE Std 1003.1-200x does not require that to be the case.
Historically, implementations reverted to open mode if the terminal was incapable of supporting full visual mode. IEEE Std 1003.1-200x requires this behavior. Historically, the open mode of vi behaved roughly equivalently to the visual mode, with the exception that only a single line from
the edit buffer (one "buffer line") was kept current at any time. This line was normally displayed on the next-to-last line of a terminal with cursor addressing (and the last line performed its normal visual functions for line-oriented commands and messages). In addition, some few commands behaved differently in open mode than in visual mode. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, $e x$ and $v i$ implementations have expected text to proceed in the usual European/Latin order of left to right, top to bottom. There is no requirement in IEEE Std 1003.1-200x that this be the case. The specification was deliberately written using words like "before", "after", "first", and "last" in order to permit implementations to support the natural text order of the language.

Historically, lines past the end of the edit buffer were marked with single tilde ( ${ }^{\prime} \sim r^{\prime}$ ) characters; that is, if the one-based display was 20 lines in length, and the last line of the file was on line one, then lines 2-20 would contain only a single $\boldsymbol{~}^{\sim}$ ' character.
Historically, the $v i$ editor attempted to display only complete lines at the bottom of the screen (it did display partial lines at the top of the screen). If a line was too long to fit in its entirety at the bottom of the screen, the screen lines where the line would have been displayed were displayed as single ' @' characters, instead of displaying part of the line. IEEE Std 1003.1-200x permits, but does not require, this behavior. Implementations are encouraged to attempt always to display a complete line at the bottom of the screen when doing scrolling or screen positioning by buffer lines.

Historically, lines marked with ' @' were also used to minimize output to dumb terminals over slow lines; that is, changes local to the cursor were updated, but changes to lines on the screen that were not close to the cursor were simply marked with an ' @' sign instead of being updated to match the current text. IEEE Std 1003.1-200x permits, but does not require this feature because it is used ever less frequently as terminals become smarter and connections are faster.

## Initialization in ex and vi

Historically, vi always had a line in the edit buffer, even if the edit buffer was "empty". For example:

1. The ex command = executed from visual mode wrote " 1 " when the buffer was empty.
2. Writes from visual mode of an empty edit buffer wrote files of a single character (a <newline>), while writes from ex mode of an empty edit buffer wrote empty files.
3. Put and read commands into an empty edit buffer left an empty line at the top of the edit buffer.
For consistency, IEEE Std 1003.1-200x does not permit any of these behaviors.
Historically, vi did not always return the terminal to its original modes; for example, ICRNL was modified if it was not originally set. IEEE Std 1003.1-200x does not permit this behavior.

## Command Descriptions in vi

Motion commands are among the most complicated aspects of vi to describe. With some exceptions, the text region and buffer type effect of a motion command on a vi command are described on a case-by-case basis. The descriptions of text regions in IEEE Std 1003.1-200x are not intended to imply direction; that is, an inclusive region from line $n$ to line $n+5$ is identical to a region from line $n+5$ to line $n$. This is of more than academic interest-movements to marks can be in either direction, and, if the wrapscan option is set, so can movements to search points. Historically, lines are always stored into buffers in text order; that is, from the start of the edit buffer to the end. IEEE Std 1003.1-200x requires conformance to historical practice.
Historically, command counts were applied to any associated motion, and were multiplicative to
any supplied motion count. For example, $2 \mathbf{c w}$ is the same as $\mathbf{c} \mathbf{2 w}$, and $\mathbf{2 c} 3 \mathbf{w}$ is the same as $\mathbf{c} \mathbf{6 w}$. IEEE Std 1003.1-200x requires this behavior. Historically, vi commands that used bigwords, words, paragraphs, and sentences as objects treated groups of empty lines, or lines that contained only <blank>s, inconsistently. Some commands treated them as a single entity, while others treated each line separately. For example, the w, W, and B commands treated groups of empty lines as individual words; that is, the command would move the cursor to each new empty line. The $\mathbf{e}$ and $\mathbf{E}$ commands treated groups of empty lines as a single word; that is, the first use would move past the group of lines. The $\mathbf{b}$ command would just beep at the user, or if done from the start of the line as a motion command, fail in unexpected ways. If the lines contained only (or ended with) <blank>s, the $\mathbf{w}$ and $\mathbf{W}$ commands would just beep at the user, the $\mathbf{E}$ and $\mathbf{e}$ commands would treat the group as a single word, and the $\mathbf{B}$ and $\mathbf{b}$ commands would treat the lines as individual words. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that all vi commands treat groups of empty or blank lines as a single entity, and that movement through lines ending with <blank>s be consistent with other movements.

Historically, vi documentation indicated that any number of double quotes were skipped after punctuation marks at sentence boundaries; however, implementations only skipped single quotes. IEEE Std 1003.1-200x requires both to be skipped.
Historically, the first and last characters in the edit buffer were word boundaries. This historical practice is required by IEEE Std 1003.1-200x.

Historically, vi attempted to update the minimum number of columns on the screen possible, which could lead to misleading information being displayed. IEEE Std 1003.1-200x makes no requirements other than that the current character being entered is displayed correctly, leaving all other decisions in this area up to the implementation.
Historically, lines were arbitrarily folded between columns of any characters that required multiple column positions on the screen, with the exception of tabs, which terminated at the right-hand margin. IEEE Std 1003.1-200x permits the former and requires the latter. Implementations that do not arbitrarily break lines between columns of characters that occupy multiple column positions should not permit the cursor to rest on a column that does not contain any part of a character.

The historical wi had a problem in that all movements were by buffer lines, not by display or screen lines. This is often the right thing to do; for example, single line movements, such as $\mathbf{j}$ or $\mathbf{k}$, should work on buffer lines. Commands like $\mathbf{d j}$, or $\mathbf{j}$., where . is a change command, only make sense for buffer lines. It is not, however, the right thing to do for screen motion or scrolling commands like <control>-D, <control>-F, and $\mathbf{H}$. If the window is fairly small, using buffer lines in these cases can result in completely random motion; for example, $\mathbf{1}<$ control>-D can result in a completely changed screen, without any overlap. This is clearly not what the user wanted. The problem is even worse in the case of the $\mathbf{H}, \mathbf{L}$, and $\mathbf{M}$ commands-as they position the cursor at the first non-<blank> of the line, they may all refer to the same location in large lines, and will result in no movement at all.

In addition, if the line is larger than the screen, using buffer lines can make it impossible to display parts of the line-there are not any commands that do not display the beginning of the line in historical $v i$, and if both the beginning and end of the line cannot be on the screen at the same time, the user suffers. Finally, the page and half-page scrolling commands historically moved to the first non-<blank> in the new line. If the line is approximately the same size as the screen, this is inadequate because the cursor before and after a <control>-D command will refer to the same location on the screen.

Implementations of $e x$ and $v i$ exist that do not have these problems because the relevant commands (<control>-B, <control>-D, <control>-F, <control>-U, <control>-Y, <control>-E, H, L, and $\mathbf{M}$ ) operate on display (screen) lines, not (edit) buffer lines.

IEEE Std 1003.1-200x does not permit this behavior by default because the standard developers believed that users would find it too confusing. However, historical practice has been relaxed. For example, ex and vi historically attempted, albeit sometimes unsuccessfully, to never put part of a line on the last lines of a screen; for example, if a line would not fit in its entirety, no part of the line was displayed, and the screen lines corresponding to the line contained single ' @' characters. This behavior is permitted, but not required by IEEE Std 1003.1-200x, so that it is possible for implementations to support long lines in small screens more reasonably without changing the commands to be oriented to the display (instead of oriented to the buffer). IEEE Std 1003.1-200x also permits implementations to refuse to edit any edit buffer containing a line that will not fit on the screen in its entirety.
The display area (for example, the value of the window edit option) has historically been "grown", or expanded, to display new text when local movements are done in displays where the number of lines displayed is less than the maximum possible. Expansion has historically been the first choice, when the target line is less than the maximum possible expansion value away. Scrolling has historically been the next choice, done when the target line is less than half a display away, and otherwise, the screen was redrawn. There were exceptions, however, in that ex commands generally always caused the screen to be redrawn. IEEE Std 1003.1-200x does not specify a standard behavior because there may be external issues, such as connection speed, the number of characters necessary to redraw as opposed to scroll, or terminal capabilities that implementations will have to accommodate.

The current line in IEEE Std 1003.1-200x maps one-to-one to a buffer line in the file. The current column does not. There are two different column values that are described by IEEE Std 1003.1-200x. The first is the current column value as set by many of the vi commands. This value is remembered for the lifetime of the editor. The second column value is the actual position on the screen where the cursor rests. The two are not always the same. For example, when the cursor is backed by a multi-column character, the actual cursor position on the screen has historically been the last column of the character in command mode, and the first column of the character in input mode.
Commands that set the current line, but that do not set the current cursor value (for example, $\mathbf{j}$ and $\mathbf{k}$ ) attempt to get as close as possible to the remembered column position, so that the cursor tends to restrict itself to a vertical column as the user moves around in the edit buffer. IEEE Std 1003.1-200x requires conformance to historical practice, requiring that the display location of the cursor on the display line be adjusted from the current column value as necessary to support this historical behavior.

Historically, only a single line (and for some terminals, a single line minus 1 column) of characters could be entered by the user for the line-oriented commands; that is, :, !, $l$, or ?. IEEE Std 1003.1-200x permits, but does not require, this limitation.
Historically, "soft" errors in vi caused the terminal to be alerted, but no error message was displayed. As a general rule, no error message was displayed for errors in command execution in $v i$, when the error resulted from the user attempting an invalid or impossible action, or when a searched-for object was not found. Examples of soft errors included $\mathbf{h}$ at the left margin, <control>-B or [[ at the beginning of the file, 2G at the end of the file, and so on. In addition, errors such as $\%, \mathbf{l l},\}, \mathbf{)}, \mathbf{N}, \mathbf{n}, \mathbf{f}, \mathbf{F}, \mathbf{t}$, and $\mathbf{T}$ failing to find the searched-for object were soft as well. Less consistently, / and ? displayed an error message if the pattern was not found, /, ?, N, and n displayed an error message if no previous regular expression had been specified, and ; did not display an error message if no previous $\mathbf{f}, \mathbf{F}, \mathbf{t}$, or $\mathbf{T}$ command had occurred. Also, behavior in this area might reasonably be based on a runtime evaluation of the speed of a network connection. Finally, some implementations have provided error messages for soft errors in order to assist naive users, based on the value of a verbose edit option. IEEE Std 1003.1-200x does not list specific errors for which an error message shall be displayed. Implementations should conform to historical practice in the absence of any strong reason to diverge.

## Page Backwards

The <control>-B and <control>-F commands historically considered it an error to attempt to page past the beginning or end of the file, whereas the <control>-D and <control>-U commands simply moved to the beginning or end of the file. For consistency, IEEE Std 1003.1-200x requires the latter behavior for all four commands. All four commands still consider it an error if the current line is at the beginning (<control>-B, <control>-U) or end (<control>-F, <control>-D) of the file. Historically, the <control>-B and <control>-F commands skip two lines in order to include overlapping lines when a single command is entered. This makes less sense in the presence of a count, as there will be, by definition, no overlapping lines. The actual calculation used by historical implementations of the vi editor for <control>-B was:
((current first line) - count $x$ (window edit option)) +2
and for <control>-F was:

```
((current first line) + count x (window edit option)) -2
```

This calculation does not work well when intermixing commands with and without counts; for example, $3<$ control>-F is not equivalent to entering the <control>-F command three times, and is not reversible by entering the <control>-B command three times. For consistency with other vi commands that take counts, IEEE Std 1003.1-200x requires a different calculation.

## Scroll Forward

The 4BSD and System V implementations of vi differed on the initial value used by the scroll command. 4BSD used:

```
((window edit option) +1) /2
```

while System V used the value of the scroll edit option. The System V version is specified by IEEE Std 1003.1-200x because the standard developers believed that it was more intuitive and permitted the user a method of setting the scroll value initially without also setting the number of lines that are displayed.

## Scroll Forward by Line

Historically, the <control>-E and <control>-Y commands considered it an error if the last and first lines, respectively, were already on the screen. IEEE Std 1003.1-200x requires conformance to historical practice. Historically, the <control>-E and <control>-Y commands had no effect in open mode. For simplicity and consistency of specification, IEEE Std 1003.1-200x requires that they behave as usual, albeit with a single line screen.

## Clear and Redisplay

The historical <control>-L command refreshed the screen exactly as it was supposed to be currently displayed, replacing any ' @' characters for lines that had been deleted but not updated on the screen with refreshed ' @' characters. The intent of the <control>-L command is to refresh when the screen has been accidentally overwritten; for example, by a write command from another user, or modem noise.

## Redraw Screen

The historical <control>-R command redisplayed only when necessary to update lines that had been deleted but not updated on the screen and that were flagged with ' @' characters. There is no requirement that the screen be in any way refreshed if no lines of this form are currently displayed. IEEE Std 1003.1-200x permits implementations to extend this command to refresh lines on the screen flagged with ' @' characters because they are too long to be displayed in the current framework; however, the current line and column need not be modified.

## Search for tagstring

Historically, the first non-<blank> at or after the cursor was the first character, and all subsequent characters that were word characters, up to the end of the line, were included. For example, with the cursor on the leading space or on the ' \#' character in the text "\#bar@", the tag was "\#bar". On the character 'b' it was "bar", and on the 'a' it was "ar". IEEE Std 1003.1-200x requires this behavior.

## Replace Text with Results from Shell Command

Historically, the $<$,$\rangle , and ! commands considered most cursor motions other than line-oriented$ motions an error; for example, the command $>/$ foo $<\mathbf{C R}>$ succeeded, while the command $>1$ failed, even though the text region described by the two commands might be identical. For consistency, all three commands only consider entire lines and not partial lines, and the region is defined as any line that contains a character that was specified by the motion.

## Move to Matching Character

Other matching characters have been left implementation-defined in order to allow extensions such as matching ${ }^{\prime}<'^{\prime}$ and ${ }^{\prime}>{ }^{\prime}$ for searching HTML, or \#ifdef, \#else, and \#endif for searching C source.

## Repeat Substitution

IEEE Std 1003.1-200x requires that any $\mathbf{c}$ and $\mathbf{g}$ flags specified to the previous substitute command be ignored; however, the $\mathbf{r}$ flag may still apply, if supported by the implementation.

## Return to Previous (Context or Section)

The [[, ]l, (, ), l, and \} commands are all affected by "section boundaries", but in some historical implementations not all of the commands recognize the same section boundaries. This is a bug, not a feature, and a unique section-boundary algorithm was not described for each command. One special case that is preserved is that the sentence command moves to the end of the last line of the edit buffer while the other commands go to the beginning, in order to preserve the traditional character cut semantics of the sentence command. Historically, vi section boundaries at the beginning and end of the edit buffer were the first non-<blank> on the first and last lines of the edit buffer if one exists; otherwise, the last character of the first and last lines of the edit buffer if one exists. To increase consistency with other section locations, this has been simplified by IEEE Std 1003.1-200x to the first character of the first and last lines of the edit buffer, or the first and the last lines of the edit buffer if they are empty.

Sentence boundaries were problematic in the historical vi. They were not only the boundaries as defined for the section and paragraph commands, but they were the first non-<blank> that occurred after those boundaries, as well. Historically, the vi section commands were documented as taking an optional window size as a count preceding the command. This was not implemented in historical versions, so IEEE Std 1003.1-200x requires that the count repeat the command, for consistency with other vi commands.

## Repeat

Historically, mapped commands other than text input commands could not be repeated using the period command. IEEE Std 1003.1-200x requires conformance to historical practice.
The restrictions on the interpretation of special characters (for example, <control>-H) in the repetition of text input mode commands is intended to match historical practice. For example, given the input sequence:

```
iab<control>-H<control>-H<control>-Hdef<escape>
```

the user should be informed of an error when the sequence is first entered, but not during a command repetition. The character <control>-T is specifically exempted from this restriction. Historical implementations of $v i$ ignored <control>-T characters that were input in the original command during command repetition. IEEE Std 1003.1-200x prohibits this behavior.

## Find Regular Expression

Historically, commands did not affect the line searched to or from if the motion command was a search ( $/, ?, \mathbf{N}, \mathbf{n}$ ) and the final position was the start/end of the line. There were some special cases and vi was not consistent. IEEE Std 1003.1-200x does not permit this behavior, for consistency. Historical implementations permitted but were u

## Shift Left (Right)

Refer to the Rationale for the! and / commands. Historically, the < and > commands sometimes moved the cursor to the first non-<blank> (for example if the command was repeated or with _ as the motion command), and sometimes left it unchanged. IEEE Std 1003.1-200x does not permit this inconsistency, requiring instead that the cursor always move to the first non-<blank>. Historically, the < and > commands did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by IEEE Std 1003.1-200x.

## Execute

Historically, buffers could execute other buffers, and loops, infinite and otherwise, were possible. IEEE Std 1003.1-200x requires conformance to historical practice. The *buffer syntax of $e x$ is not required in $v i$, because it is not historical practice and has been used in some $v i$ implementations to support additional scripting languages.

## Reverse Case

Historically, the ~ command ignored any associated count, and acted only on the characters in the current line. For consistency with other vi commands, IEEE Std 1003.1-200x requires that an associated count act on the next count characters, and that the command move to subsequent lines if warranted by count, to make it possible to modify large pieces of text in a reasonably efficient manner. There exist $v i$ implementations that optionally require an associated motion command for the ~ command. Implementations supporting this functionality are encouraged to base it on the tildedop edit option and handle the text regions and cursor positioning identically to the yank command.

## Append

Historically, counts specified to the $\mathbf{A}, \mathbf{a}, \mathbf{I}$, and $\mathbf{i}$ commands repeated the input of the first line count times, and did not repeat the subsequent lines of the input text. IEEE Std 1003.1-200x requires that the entire text input be repeated count times.

## Move Backward to Preceding Word

Historically, $v i$ became confused if word commands were used as motion commands in empty files. IEEE Std 1003.1-200x requires that this be an error. Historical implementations of $v i$ had a large number of bugs in the word movement commands, and they varied greatly in behavior in the presence of empty lines, "words" made up of a single character, and lines containing only <blank>s. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

## Change to End-of-Line

Some historical implementations of the $\mathbf{C}$ command did not behave as described by IEEE Std 1003.1-200x when the $\$$ key was remapped because they were implemented by pushing the $\$$ key onto the input queue and reprocessing it. IEEE Std 1003.1-200x does not permit this behavior. Historically, the C, S, and s commands did not copy replaced text into the numeric buffers. For consistency and simplicity of specification, IEEE Std 1003.1-200x requires that they behave like their respective commands in all respects.

## Delete

Historically, lines in open mode that were deleted were scrolled up, and an @ glyph written over the beginning of the line. In the case of terminals that are incapable of the necessary cursor motions, the editor erased the deleted line from the screen. IEEE Std 1003.1-200x requires conformance to historical practice; that is, if the terminal cannot display the ' ${ }^{\prime}$ ' character, the line cannot remain on the screen.

## Delete to End-of-Line

Some historical implementations of the $\mathbf{D}$ command did not behave as described by IEEE Std 1003.1-200x when the $\$$ key was remapped because they were implemented by pushing the $\$$ key onto the input queue and reprocessing it. IEEE Std 1003.1-200x does not permit this behavior.

## Join

An historical oddity of $v i$ is that the commands $\mathbf{J}, \mathbf{1} \mathbf{J}$, and $\mathbf{2 J}$ are all equivalent. IEEE Std 1003.1-200x requires conformance to historical practice. The $v i \mathbf{J}$ command is specified in terms of the ex join command with an ex command count value. The address correction for a count that is past the end of the edit buffer is necessary for historical compatibility for both ex and $v i$.

## Mark Position

Historical practice is that only lowercase letters, plus ' ${ }^{\prime \prime}$ and ${ }^{\prime \prime}$ ', could be used to mark a cursor position. IEEE Std 1003.1-200x requires conformance to historical practice, but encourages implementations to support other characters as marks as well.

## Repeat Regular Expression Find (Forward and Reverse)

Historically, the $\mathbf{N}$ and $\mathbf{n}$ commands could not be used as motion components for the $\mathbf{c}$ command. With the exception of the $\mathbf{c N}$ command, which worked if the search crossed a line boundary, the text region would be discarded, and the user would not be in text input mode. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

## Insert Empty Line (Below and Above)

Historically, counts to the $\mathbf{O}$ and $\mathbf{o}$ commands were used as the number of physical lines to open, if the terminal was dumb and the slowopen option was not set. This was intended to minimize traffic over slow connections and repainting for dumb terminals. IEEE Std 1003.1-200x does not permit this behavior, requiring that a count to the open command behave as for other text input commands. This change to historical practice was made for consistency, and because a superset of the functionality is provided by the slowopen edit option.

## Put from Buffer (Following and Before)

Historically, counts to the $\mathbf{p}$ and $\mathbf{P}$ commands were ignored if the buffer was a line mode buffer, but were (mostly) implemented as described in IEEE Std 1003.1-200x if the buffer was a character mode buffer. Because implementations exist that do not have this limitation, and because pasting lines multiple times is generally useful, IEEE Std 1003.1-200x requires that count be supported for all $\mathbf{p}$ and $\mathbf{P}$ commands.
Historical implementations of $v i$ were widely known to have major problems in the $\mathbf{p}$ and $\mathbf{P}$ commands, particularly when unusual regions of text were copied into the edit buffer. The standard developers viewed these as bugs, and they are not permitted for consistency and simplicity of specification.
Historically, a $\mathbf{P}$ or $\mathbf{p}$ command (or an ex put command executed from open or visual mode)
executed in an empty file, left an empty line as the first line of the file. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

## Replace Character

Historically, the $\mathbf{r}$ command did not correctly handle the erase and word erase characters as arguments, nor did it handle an associated count greater than 1 with a <carriage-return> argument, for which it replaced count characters with a single <newline>. IEEE Std 1003.1-200x does not permit these inconsistencies.
Historically, the $\mathbf{r}$ command permitted the <control>-V escaping of entered characters, such as <ESC> and the <carriage-return>; however, it required two leading <control>-V characters instead of one. IEEE Std 1003.1-200x requires that this be changed for consistency with the other text input commands of $v i$.
Historically, it is an error to enter the $\mathbf{r}$ command if there are less than count characters at or after the cursor in the line. While a reasonable and unambiguous extension would be to permit the $\mathbf{r}$ command on empty lines, it would require that too large a count be adjusted to match the number of characters at or after the cursor for consistency, which is sufficiently different from historical practice to be avoided. IEEE Std 1003.1-200x requires conformance to historical practice.

## Replace Characters

Historically, if there were autoindent characters in the line on which the $\mathbf{R}$ command was run, and autoindent was set, the first <newline> would be properly indented and no characters would be replaced by the <newline>. Each additional <newline> would replace $n$ characters, where $n$ was the number of characters that were needed to indent the rest of the line to the proper indentation level. This behavior is a bug and is not permitted by IEEE Std 1003.1-200x.

## Undo

Historical practice for cursor positioning after undoing commands was mixed. In most cases, when undoing commands that affected a single line, the cursor was moved to the start of added or changed text, or immediately after deleted text. However, if the user had moved from the line being changed, the column was either set to the first non-<blank>, returned to the origin of the command, or remained unchanged. When undoing commands that affected multiple lines or entire lines, the cursor was moved to the first character in the first line restored. As an example of how inconsistent this was, a search, followed by an o text input command, followed by an undo would return the cursor to the location where the o command was entered, but a cw command followed by an o command followed by an undo would return the cursor to the first non-<blank> of the line. IEEE Std 1003.1-200x requires the most useful of these behaviors, and discards the least useful, in the interest of consistency and simplicity of specification.

## Yank

Historically, the yank command did not move to the end of the motion if the motion was in the forward direction. It moved to the end of the motion if the motion was in the backward direction, except for the _ command, or for the G and ' commands when the end of the motion was on the current line. This was further complicated by the fact that for a number of motion commands, the yank command moved the cursor but did not update the screen; for example, a subsequent command would move the cursor from the end of the motion, even though the cursor on the screen had not reflected the cursor movement for the yank command. IEEE Std 1003.1-200x requires that all yank commands associated with backward motions move the cursor to the end of the motion for consistency, and specifically, to make ' commands as motions consistent with search patterns as motions.

## Yank Current Line

Some historical implementations of the $\mathbf{Y}$ command did not behave as described by IEEE Std 1003.1-200x when the ' -' key was remapped because they were implemented by pushing the ' _' key onto the input queue and reprocessing it. IEEE Std 1003.1-200x does not permit this behavior.

## Redraw Window

Historically, the $\mathbf{z}$ command always redrew the screen. This is permitted but not required by IEEE Std 1003.1-200x, because of the frequent use of the $\mathbf{z}$ command in macros such as map $\mathbf{n} \mathbf{n z}$. for screen positioning, instead of its use to change the screen size. The standard developers believed that expanding or scrolling the screen offered a better interface for users. The ability to redraw the screen is preserved if the optional new window size is specified, and in the <control>-L and <control>-R commands.

The semantics of $\mathbf{z}^{\wedge}$ are confusing at best. Historical practice is that the screen before the screen that ended with the specified line is displayed. IEEE Std 1003.1-200x requires conformance to historical practice.

Historically, the $\mathbf{z}$ command would not display a partial line at the top or bottom of the screen. If the partial line would normally have been displayed at the bottom of the screen, the command worked, but the partial line was replaced with ' @' characters. If the partial line would normally have been displayed at the top of the screen, the command would fail. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

Historically, the z command with a line specification of 1 ignored the command. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.
Historically, the z command did not set the cursor column to the first non-<blank> for the character if the first screen was to be displayed, and was already displayed. For consistency and simplicity of specification, IEEE Std 1003.1-200x does not permit this behavior.

## Input Mode Commands in vi

Historical implementations of vi did not permit the user to erase more than a single line of input, or to use normal erase characters such as line erase, worderase, and erase to erase autoindent characters. As there exist implementations of vi that do not have these limitations, both behaviors are permitted, but only historical practice is required. In the case of these extensions, $v i$ is required to pause at the autoindent and previous line boundaries.
Historical implementations of vi updated only the portion of the screen where the current cursor character was displayed. For example, consider the $v i$ input keystrokes:

```
iabcd<escape>0c<tab>
```

Historically, the <tab> would overwrite the characters "abcd" when it was displayed. Other implementations replace only the ' $a^{\prime}$ character with the $<$ tab $>$, and then push the rest of the characters ahead of the cursor. Both implementations have problems. The historical implementation is probably visually nicer for the above example; however, for the keystrokes:

```
iabcd<ESC>0R<tab><ESC>
```

the historical implementation results in the string "bcd" disappearing and then magically reappearing when the $<$ ESC $>$ character is entered. IEEE Std 1003.1-200x requires the former behavior when overwriting erase-columns-that is, overwriting characters that are no longer logically part of the edit buffer-and the latter behavior otherwise.
Historical implementations of vi discarded the <control>-D and <control>-T characters when they were entered at places where their command functionality was not appropriate. IEEE Std 1003.1-200x requires that the <control>-T functionality always be available, and that
<control>-D be treated as any other key when not operating on autoindent characters.

## NUL

Some historical implementations of $v i$ limited the number of characters entered using the NUL input character to 256 bytes. IEEE Std 1003.1-200x permits this limitation; however, implementations are encouraged to remove this limit.

## <control>-D

See also Rationale for the input mode command <newline>. The hidden assumptions in the <control>-D command (and in the $v i$ autoindent specification in general) is that <space>s take up a single column on the screen and that <tab>s are comprised of an integral number of <space>s.

## <newline>

Implementations are permitted to rewrite autoindent characters in the line when <newline>, <carriage-return>, <control>-D, and <control>-T are entered, or when the shift commands are used, because historical implementations have both done so and found it necessary to do so. For example, a <control>-D when the cursor is preceded by a single <tab>, with tabstop set to 8 , and shiftwidth set to 3, will result in the <tab> being replaced by several <space>s.

## <control>-T

See also the Rationale for the input mode command <newline>. Historically, <control>-T only worked if no non-<blank>s had yet been input in the current input line. In addition, the characters inserted by <control>-T were treated as autoindent characters, and could not be erased using normal user erase characters. Because implementations exist that do not have these limitations, and as moving to a column boundary is generally useful, IEEE Std 1003.1-200x requires that both limitations be removed.

## <control>-V

Historically, vi used ${ }^{\wedge} \mathbf{V}$, regardless of the value of the literal-next character of the terminal. IEEE Std 1003.1-200x requires conformance to historical practice.
The uses described for <control>-V can also be accomplished with <control>-Q, which is useful on terminals that use <control>-V for the down-arrow function. However, most historical implementations use <control>-Q for the termios START character, so the editor will generally not receive the <control>-Q unless stty ixon mode is set to off. (In addition, some historical implementations of $v i$ explicitly set ixon mode to on, so it was difficult for the user to set it to off.) Any of the command characters described in IEEE Std 1003.1-200x can be made ineffective by their selection as termios control characters, using the stty utility or other methods described in the System Interfaces volume of IEEE Std 1003.1-200x.

## <ESC>

Historically, SIGINT alerted the terminal when used to end input mode. This behavior is permitted, but not required, by IEEE Std 1003.1-200x.

## FUTURE DIRECTIONS

## None.

## SEE ALSO

ed, ex, stty

## CHANGE HISTORY

First released in Issue 2.
Issue 5
The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the User Portability Utilities option.
The APPLICATION USAGE section is added.
The obsolescent SYNOPSIS is removed.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The reindent command description is added.

The vi utility has been extensively rewritten for alignment with the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 \#57, \#62, \#63, \#64, \#78, and \#188 are applied.
IEEE PASC Interpretation 1003.2 \#207 is applied, clarifying the description of the $\mathbf{R}$ command in a manner similar to the descriptions of other text input mode commands such as $\mathbf{i}, \mathbf{0}$, and $\mathbf{O}$.

The -1 option is removed.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/41 is applied, adding [count] to the Synopsis for [[.
IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/42 is applied, adding [count] to the Synopsis for l].
Issue 7
Austin Group Interpretation 1003.1-2001 \#027 is applied, clarifying that ' + ' may be recognized as an option delimiter in the OPTIONS section.

Austin Group Interpretation 1003.1-2001 \#087 is applied, updating the Put from Buffer Before ( $\mathbf{( P )}$ command description to address multi-line requirements.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

NAME
wait - await process completion

## SYNOPSIS

```
wait [pid...]
```

## DESCRIPTION

When an asynchronous list (see Section 2.9.3.1 (on page 50)) is started by the shell, the process ID of the last command in each element of the asynchronous list shall become known in the current shell execution environment; see Section 2.12 (on page 61).
If the wait utility is invoked with no operands, it shall wait until all process IDs known to the invoking shell have terminated and exit with a zero exit status.
If one or more pid operands are specified that represent known process IDs, the wait utility shall wait until all of them have terminated. If one or more pid operands are specified that represent unknown process IDs, wait shall treat them as if they were known process IDs that exited with exit status 127. The exit status returned by the wait utility shall be the exit status of the process requested by the last pid operand.

The known process IDs are applicable only for invocations of wait in the current shell execution environment.

## OPTIONS

None.
OPERANDS
The following operand shall be supported:
pid One of the following:

1. The unsigned decimal integer process ID of a command, for which the utility is to wait for the termination.
2. A job control job ID (see the Base Definitions volume of IEEE Std 1003.1-200x, Section 3.203, Job Control Job ID) that identifies a background process group to be waited for. The job control job ID notation is applicable only for invocations of wait in the current shell execution environment; see Section 2.12 (on page 61). The exit status of wait shall be determined by the last command in the pipeline.
Note: The job control job ID type of pid is only available on systems supporting the User Portability Utilities option.

## STDIN

Not used.

## INPUT FILES

None.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of wait:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

```
\(L C \_A L L\) If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
```

## ASYNCHRONOUS EVENTS

```
Default.
```

## STDOUT

```
Not used.
```

## STDERR

```
The standard error shall be used only for diagnostic messages.
```

## OUTPUT FILES

```
None.
```

## EXTENDED DESCRIPTION

```
None.
```

## EXIT STATUS

```
If one or more operands were specified, all of them have terminated or were not known by the invoking shell, and the status of the last operand specified is known, then the exit status of wait shall be the exit status information of the command indicated by the last operand specified. If the process terminated abnormally due to the receipt of a signal, the exit status shall be greater than 128 and shall be distinct from the exit status generated by other signals, but the exact value is unspecified. (See the kill -l option.) Otherwise, the wait utility shall exit with one of the following values:
0 The wait utility was invoked with no operands and all process IDs known by the invoking shell have terminated.
1-126 The wait utility detected an error.
127 The command identified by the last pid operand specified is unknown.
```

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

On most implementations, wait is a shell built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:
(wait)
nohup wait ...
find . -exec wait ... \;
it returns immediately because there are no known process IDs to wait for in those environments.

Historical implementations of interactive shells have discarded the exit status of terminated background processes before each shell prompt. Therefore, the status of background processes was usually lost unless it terminated while wait was waiting for it. This could be a serious problem when a job that was expected to run for a long time actually terminated quickly with a syntax or initialization error because the exit status returned was usually zero if the requested
process ID was not found. This volume of IEEE Std 1003.1-200x requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

```
j1&
p1=$!
j2&
wait $p1
echo Job 1 exited with status $?
wait $!
echo Job 2 exited with status $?
```

work without losing status on any of the jobs. The shell is allowed to discard the status of any process if it determines that the application cannot get the process ID for that process from the shell. It is also required to remember only $\left\{C H I L D \_M A X\right\}$ number of processes in this way. Since the only way to get the process ID from the shell is by using the '!' shell parameter, the shell is allowed to discard the status of an asynchronous list if "\$!" was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference "\$!". If the implementation of the shell is smart enough to determine that a reference to "\$!" was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to wait with no operands discards the exit status of all asynchronous lists.)

If the exit status of wait is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.

## EXAMPLES

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably determine which signal by using kill as shown by the following script:

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l $?) signal.
```

If the following sequence of commands is run in less than 31 seconds:

```
sleep 257 | sleep 31 &
```

jobs -l \% \%
either of the following commands returns the exit status of the second sleep in the pipeline:

```
wait <pid of sleep 31>
```

wait \% \%

## RATIONALE

The description of wait does not refer to the waitpid() function from the System Interfaces volume of IEEE Std 1003.1-200x because that would needlessly overspecify this interface. However, the wording means that wait is required to wait for an explicit process when it is given an argument so that the status information of other processes is not consumed. Historical implementations use the wait() function defined in the System Interfaces volume of IEEE Std 1003.1-200x until wait () returns the requested process ID or finds that the requested process does not exist. Because this means that a shell script could not reliably get the status of all background children if a second background job was ever started before the first job finished,
it is recommended that the wait utility use a method such as the functionality provided by the waitpid( ) function.

The ability to wait for multiple pid operands was adopted from the KornShell.
This new functionality was added because it is needed to determine the exit status of any asynchronous list accurately. The only compatibility problem that this change creates is for a script like

```
while sleep 60 do
    job& echo Job started $(date) as $! done
```

which causes the shell to monitor all of the jobs started until the script terminates or runs out of memory. This would not be a problem if the loop did not reference "\$!" or if the script would occasionally wait for jobs it started.

## FUTURE DIRECTIONS

## CHANGE HISTORY

First released in Issue 2.

NAME
wc - word, line, and byte or character count

## SYNOPSIS

> wc [-c|-m] [-lw] [file...]

## DESCRIPTION

The wc utility shall read one or more input files and, by default, write the number of <newline>s, words, and bytes contained in each input file to the standard output.

The utility also shall write a total count for all named files, if more than one input file is specified.
The wo utility shall consider a word to be a non-zero-length string of characters delimited by white space.

## OPTIONS

The wc utility shall conform to the Base Definitions yolume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-c Write to the standard output the number of bytes in each input file.
-1 Write to the standard output the number of <newline>s in each input file.
$-\mathbf{m} \quad$ Write to the standard output the number of characters in each input file.
$-\mathbf{w} \quad$ Write to the standard output the number of words in each input file.
When any option is specified, wc shall report only the information requested by the specified options.

## OPERANDS

The following operand shall be supported:
file A pathname of an input file. If no file operands are specified, the standard input shall be used.

## STDIN

The standard input shall be used only if no file operands are specified. See the INPUT FILES section.

## INPUT FILES

The input files may be of any type.

## ENVIRONMENT VARIABLES

The following environment yariables shall affect the execution of $w c$ :
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and which characters are defined as white space characters.

LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

By default, the standard output shall contain an entry for each input file of the form:
"\%d \%d \%d \%s\n", <newlines>, <words>, <bytes>, <file>
If the $-\mathbf{m}$ option is specified, the number of characters shall replace the <bytes> field in this format.

If any options are specified and the -1 option is not specified, the number of <newline>s shall not be written.

If any options are specified and the $-\mathbf{w}$ option is not specified, the number of words shall not be written.

If any options are specified and neither $-\mathbf{c}$ nor $-\mathbf{m}$ is specified, the number of bytes or characters shall not be written.

If no input file operands are specified, no name shall be written and no <blank>s preceding the pathname shall be written.
If more than one input file operand is specified, an additional line shall be written, of the same format as the other lines, except that the word total (in the POSIX locale) shall be written instead of a pathname and the total of each column shall be written as appropriate. Such an additional line, if any, is written at the end of the output.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

The $-\mathbf{m}$ option is not a switch, but an option at the same level as $-\mathbf{c}$. Thus, to produce the full default output with character counts instead of bytes, the command required is:

```
wc -mlw
```

## EXAMPLES

None.

## RATIONALE

The output file format pseudo-printf() string differs from the System $V$ version of $w c$ :
"\%7d\%7d\%7d \%s $\backslash n "$
which produces possibly ambiguous and unparsable results for very large files, as it assumes no number shall exceed six digits.
Some historical implementations use only <space>, <tab>, and <newline> as word separators. The equivalent of the ISO C standard isspace () function is more appropriate.
The -c option stands for "character" count, even though it counts bytes. This stems from the sometimes erroneous historical view that bytes and characters are the same size. Due to international requirements, the $-\mathbf{m}$ option (reminiscent of "multi-byte") was added to obtain actual character counts.

Early proposals only specified the results when input files were text files. The current specification more closely matches historical practice. (Bytes, words, and <newline>s are counted separately and the results are written when an end-of-file is detected.)
Historical implementations of the wc utility only accepted one argument to specify the options $-\mathbf{c},-\mathbf{l}$, and $-\mathbf{w}$. Some of them also had multiple occurrences of an option cause the corresponding count to be written multiple times and had the order of specification of the options affect the order of the fields on output, but did not document either of these. Because common usage either specifies no options or only one option, and because none of this was documented, the changes required by this volume of IEEE Std 1003.1-200x should not break many historical applications (and do not break any historical conforming applications).

## CHANGE HISTORY

First released in Issue 2.
Issue 7
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

```
NAME
what - identify SCCS files (DEVELOPMENT)
```

## SYNOPSIS

```
xsi what [-s] file...
```

## DESCRIPTION

```
The what utility shall search the given files for all occurrences of the pattern that get (see get) substitutes for the \%Z\% keyword ("@(\#)") and shall write to standard output what follows until the first occurrence of one of the following:
" > newline \ NUL
```

## OPTIONS

```
The what utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.
The following option shall be supported:
-s Quit after finding the first occurrence of the pattern in each file.
```

## OPERANDS

```
The following operands shall be supported:
file A pathname of a file to search.
```

## STDIN

```
Not used.
INPUT FILES
The input files shall be of any file type.
```

## ENVIRONMENT VARIABLES

```
The following environment variables shall affect the execution of what:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
```

## ASYNCHRONOUS EVENTS

```
Default.
```

## STDOUT

The standard output shall consist of the following for each file operand:
"\%s: \n\t\%s\n", <pathname>, <identification string>

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 Any matches were found.
1 Otherwise.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The what utility is intended to be used in conjunction with the SCCS command get, which automatically inserts identifying information, but it can also be used where the information is inserted by any other means.
When the string "@(\#)" is included in a library routine in a shared library, it might not be found in an a.out file using that library routine.

## EXAMPLES

If the C -language program in file f.c contains:

```
char ident[] = "@(#)identification information";
```

and $f . c$ is compiled to yield f.o and a.out, then the command:

```
what f.c f.o a.out
```

writes:
f.c:
identification information
f.o:
identification information
a. out:
identification information

## RATIONALE

None.

## NAME

who - display who is on the system

## SYNOPSIS

```
who [-mTu]
who [-mu] -s [-bHlprt] [file]
who [-mTu] [-abdHlprt] [file]
who -q [file]
who am i
who am I
```

## DESCRIPTION

The who utility shall list various pieces of information about accessible users. The domain of accessibility is implementation-defined.

Based on the options given, who can also list the user's name, terminal line, login time, elapsed time since activity occurred on the line, and the process ID of the command interpreter for each current system user.

## OPTIONS

The who utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported. The metavariables, such as <

| 41291 | XSI | -t | Indicate the last change to the system clock. |
| :---: | :---: | :---: | :---: |
| 41292 |  | -T | Show the state of each terminal, as described in the STDOUT section. |
| 41293 |  | -u | Write "idle time" for each displayed user in addition to any other information. The |
| 41294 |  |  | idle time is the time since any activity occurred on the user's terminal. The method |
| 41295 | XSI |  | of determining this is unspecified. This option shall list only those users who are |
| 41296 |  |  | currently logged in. The <name> is the user's login name. The <line> is the name |
| 41297 |  |  | of the line as found in the directory /dev. The <time> is the time that the user |
| 41298 |  |  | logged in. The <activity> is the number of hours and minutes since activity last |
| 41299 |  |  | occurred on that particular line. A dot indicates that the terminal has seen activity |
| 41300 |  |  | in the last minute and is therefore "current". If more than twenty-four hours have |
| 41301 |  |  | elapsed or the line has not been used since boot time, the entry shall be marked |
| 41302 |  |  | <old>. This field is useful when trying to determine whether a person is working at |
| 41303 |  |  | the terminal or not. The <pid> is the process ID of the user's login process. |
| 41304 | OPERANDS |  |  |
| 41305 | XSI | The following operands shall be supported: |  |
| 41306 |  | am i, am I | In the POSIX locale, limit the output to describing the invoking user, equivalent to |
| 41307 |  |  | the $-\mathbf{m}$ option. The am and $\mathbf{i}$ or I must be separate arguments. |
| 41308 |  | file | Specify a pathname of a file to substitute for the implementation-defined database |
| 41309 |  |  | of logged-on users that who uses by default. |
| 41310 | STDIN |  |  |
| 41311 | Not used. |  |  |
| 41312 | INPUT FILES |  |  |
| 41313 | None. |  |  |
| 41314 | ENVIRONMENT VARIABLES |  |  |
| 41315 | The following environment variables shall affect the execution of who: |  |  |
| 41316 | LANG |  | Provide a default value for the internationalization variables that are unset or null. |
| 41317 |  |  | (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, |
| 41318 |  |  | Internationalization Variables for the precedence of internationalization variables |
| 41319 |  |  | used to determine the values of locale categories.) |
| 41320 | LC_ALL |  | If set to a non-empty string value, override the values of all the other |
| 41321 |  |  | internationalization variables. |
| 41322 |  | LC_CTYPE | Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments). |
| 41323 |  |  |  |
| 41324 |  |  |  |
| 41325 | LC_MESSAGES |  |  |
| 41326 | Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error. |  |  |
| 41327 |  |  |  |  |  |
| 41328 | XSI | LC_TIME | Determine the locale used for the format and contents of the date and time strings. |
| 41329 |  | NLSPATH | Determine the location of message catalogs for the processing of LC_MESSAGES. |
| 41330 41331 |  | TZ | Determine the timezone used when writing date and time information. If $T Z$ is unset or null, an unspecified default timezone shall be used. |

## ASYNCHRONOUS EVENTS

Default.

## STDOUT

The who utility shall write its default format to the standard output in an implementationdefined format, subject only to the requirement of containing the information described above.
XSI OF XSI-conformant systems shall write the default information to the standard output in the following general format:

```
<name>[<state>]<line><time>[<activity>] [<pid>] [<comment>] [<exit>]
```

For the -b option, <line> shall be "system boot". The <name> is unspecified.
The following format shall be used for the $-\mathbf{T}$ option:

```
"%s %c %s %s\n" <name>, <terminal state>, <terminal name>,
        <time of login>
```

where <terminal state> is one of the following characters:
$+\quad$ The terminal allows write access to other users.

- $\quad$ The terminal denies write access to other users.
? The terminal write-access state cannot be determined.
<space> This entry is not associated with a terminal.
In the POSIX locale, the <time of login> shall be equivalent in format to the output of:
date $+" \%$ \% $\%$ \% $\mathrm{H}: \% \mathrm{M"}$
If the $-\mathbf{u}$ option is used with $-\mathbf{T}$, the idle time shall be added to the end of the previous format in an unspecified format.

## STDERR

The standard error shall be used only for diagnostic messages.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

## None.

EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
$>0$ An error occurred.

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The name init used for the system process is the most commonly used on historical systems, but it may vary.

The "domain of accessibility" referred to is a broad concept that permits interpretation either on a very secure basis or even to allow a network-wide implementation like the historical rwho.

## EXAMPLES

## None.

## RATIONALE

Due to differences between historical implementations, the base options provided were a compromise to allow users to work with those functions. The standard developers also considered removing all the options, but felt that these options offered users valuable functionality. Additional options to match historical systems are available on XSI-conformant systems.

It is recognized that the who

NAME
write - write to another user

## SYNOPSIS

```
write user_name [terminal]
```

## DESCRIPTION

The write utility shall read lines from the standard input and write them to the terminal of the specified user. When first invoked, it shall write the message:

Message from sender-login-id (sending-terminal) [date]...
to user_name. When it has successfully completed the connection, the sender's terminal shall be alerted twice to indicate that what the sender is typing is being written to the recipient's terminal.
If the recipient wants to reply, this can be accomplished by typing:
write sender-login-id [sending-terminal]
upon receipt of the initial message. Whenever a line of input as delimited by an NL, EOF, or EOL special character (see the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface) is accumulated while in canonical input mode, the accumulated data shall be written on the other user's terminal. Characters shall be processed as follows:

- Typing <alert> shall write the alert character to the recipient's terminal.
- Typing the erase and kill characters shall affect the sender's terminal in the manner described by the termios interface in the Base Definitions volume of IEEE Std 1003.1-200x, Chapter 11, General Terminal Interface.
- Typing the interrupt or end-of-file characters shall cause write to write an appropriate message ("EOT <br>{" in the POSIX locale) to the recipient's terminal and exit. }
- Typing characters from LC_CTYPE classifications print or space shall cause those characters to be sent to the recipient's terminal.
- When and only when the stty iexten local mode is enabled, the existence and processing of additional special control characters and multi-byte or single-byte functions is implementation-defined.
- Typing other non-printable characters shall cause implementation-defined sequences of printable characters to be written to the recipient's terminal.
To write to a user who is logged in more than once, the terminal argument can be used to indicate which terminal to write to; otherwise, the recipient's terminal is selected in an implementation-defined manner and an informational message is written to the sender's standard output, indicating which terminal was chosen.
Permission to be a recipient of a write message can be denied or granted by use of the mesg utility. However, a user's privilege may further constrain the domain of accessibility of other users' terminals. The write utility shall fail when the user lacks the appropriate privileges to perform the requested action.

## OPTIONS

None.

## OPERANDS

```
The following operands shall be supported:
user_name Login name of the person to whom the message shall be written. The application shall ensure that this operand is of the form returned by the who utility.
terminal Terminal identification in the same format provided by the who utility.
```

## STDIN

```
Lines to be copied to the recipient's terminal are read from standard input.
```

## INPUT FILES

```
None.
```

## ENVIRONMENT VARIABLES

```
The following environment variables shall affect the execution of write:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables,
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files). If the recipient's locale does not use an LC_CTYPE equivalent to the sender's, the results are undefined.
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error and informative messages written to standard output.
xSI NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
```

## ASYNCHRONOUS EVENTS

```
If an interrupt signal is received, write shall write an appropriate message on the recipient's terminal and exit with a status of zero. It shall take the standard action for all other signals.
```

## STDOUT

```
An informational message shall be written to standard output if a recipient is logged in more than once.
```

## STDERR

```
The standard error shall be used only for diagnostic messages.
```

## OUTPUT FILES

```
The recipient's terminal is used for output.
```

## EXTENDED DESCRIPTION

```
None.
```

## EXIT STATUS

```
The following exit values shall be returned:
0 Successful completion.
\(>0\) The addressed user is not logged on or the addressed user denies permission.
```

## CONSEQUENCES OF ERRORS

## Default.

## APPLICATION USAGE

The talk utility is considered by some users to be a more usable utility on full-screen terminals.

## EXAMPLES

None.

## RATIONALE

The write utility was included in this volume of IEEE Std 1003.1-200x since it can be implemented on all terminal types. The standard developers considered the talk utility, which cannot be implemented on certain terminals, to be a "better" communications interface. Both of these programs are in widespread use on historical implementations. Therefore, the standard developers decided that both utilities should be specified.
The format of the terminal name is unspecified, but the descriptions of $p s$, talk, who, and write require that they all use or accept the same format.

## FUTURE DIRECTIONS

None.

mesg, talk, who, the Base Definitions yolume of IEEE Std 1003.1-200x,

## NAME

xargs - construct argument lists and invoke utility

## SYNOPSIS

```
xSI xargs [-ptx] [-E eofstr] [-s size] [-I replstr] [-L number] [-n number]
    [utility [argument...]]
```

## DESCRIPTION

The xargs utility shall construct a command line consisting of the utility and argument operands specified followed by as many arguments read in sequence from standard input as fit in length and number constraints specified by the options. The xargs utility shall then invoke the constructed command line and wait for its completion. This sequence shall be repeated until one of the following occurs:

- An end-of-file condition is detected on standard input.
- An argument consisting of just the logical end-of-file string (see the -E eofstr option) is found on standard input after double-quote processing, apostrophe processing, and backslash escape processing (see next paragraph). All arguments up to but not including the argument consisting of just the logical end-of-file string shall be used as arguments in constructed command lines.
- An invocation of a constructed command line returns an exit status of 255.

The application shall ensure that arguments in the standard input are separated by unquoted <blank>s, unescaped <blank>s, or <newline>s. A string of zero or more non-double-quote ( ${ }^{\prime}{ }^{\prime}$ ) characters and non-<newline>s can be quoted by enclosing them in double-quotes. A string of zero or more non-apostrophe ( $\prime^{\prime \prime}$ ) characters and non-<newline>s can be quoted by enclosing them in apostrophes. Any unquoted character can be escaped by preceding it with a backslash. The utility named by utility shall be executed one or more times until the end-of-file is reached or the logical end-of file string is found. The results are unspecified if the utility named by utility attempts to read from its standard input.

The generated command line length shall be the sum of the size in bytes of the utility name and each argument treated as strings, including a null byte terminator for each of these strings. The xargs utility shall limit the command line length such that when the command line is invoked, the combined argument and environment lists (see the exec family of functions in the System Interfaces volume of IEEE Std 1003.1-200x) shall not exceed \{ARG_MAX\}-2048 bytes. Within this constraint, if neither the $-\mathbf{n}$ nor the $-\mathbf{s}$ option is specified, the default command line length shall be at least \{LINE_MAX\}.

## OPTIONS

The xargs utility shall conform to the Base Definitions volume of IEEE Std 1003.1-200x, Section 12.2, Utility Syntax Guidelines.

The following options shall be supported:
-E eofstr Use eofstr as the logical end-of-file string. If -E is not specified, it is unspecified whether the logical end-of-file string is the underscore character ( ${ }^{\prime} \quad{ }^{\prime}$ ) or the end-of-file string capability is disabled. When eofstr is the null string, the logical end-offile string capability shall be disabled and underscore characters shall be taken literally.

XSI
-I replstr Insert mode: utility is executed for each line from standard input, taking the entire line as a single argument, inserting it in arguments for each occurrence of replstr. A maximum of five arguments in arguments can each contain one or more instances of replstr. Any <blank>s at the beginning of each line shall be ignored.

detected immediately following an escaped <newline>.

## INPUT FILES

The file /dev/tty shall be used to read responses required by the $-\mathbf{p}$ option.

## ENVIRONMENT VARIABLES

The following environment variables shall affect the execution of xargs:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
$L C \_A L L$ If set to a non-empty string value, override the values of all the other internationalization variables.
LC_COLLATE
Determine the locale for the behavior of ranges, equivalence classes, and multicharacter collating elements used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files) and the behavior of character classes used in the extended regular expression defined for the yesexpr locale keyword in the LC_MESSAGES category.
LC_MESSAGES
Determine the locale for the processing of affirmative responses and that should be used to affect the format and contents of diagnostic messages written to standard error.

XSI
NLSPATH $\quad$ Determine the location of message catalogs for the processing of LC_MESSAGES.
PATH

## ASYNCHRONOUS EVENTS

## Default.

## STDOUT

Not used.

## STDERR

The standard error shall be used for diagnostic messages and the $-\mathbf{t}$ and $-\mathbf{p}$ options. If the $-\mathbf{t}$ option is specified, the utility and its constructed argument list shall be written to standard error, as it will be invoked, prior to invocation. If $-\mathbf{p}$ is specified, a prompt of the following format shall be written (in the POSIX locale):
"?..."
at the end of the line of the output from $-\mathbf{t}$.

## OUTPUT FILES

None.

## EXTENDED DESCRIPTION

None.

## EXIT STATUS

The following exit values shall be returned:
0 All invocations of utility returned exit status zero.

1-125 A command line meeting the specified requirements could not be assembled, one or more of the invocations of utility returned a non-zero exit status, or some other error occurred.

126 The utility specified by utility was found but could not be invoked.
127 The utility specified by utility could not be found.

## CONSEQUENCES OF ERRORS

If a command line meeting the specified requirements cannot be assembled, the utility cannot be invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits with exit status 255, the xargs utility shall write a diagnostic message and exit without processing any remaining input.

## APPLICATION USAGE

The 255 exit status allows a utility being used by xargs to tell xargs to terminate if it knows no further invocations using the current data stream will succeed. Thus, utility should explicitly exit with an appropriate value to avoid accidentally returning with 255.

Note that input is parsed as lines; <blank>s separate arguments. If xargs is used to bundle output of commands like find dir -print or $l s$ into commands to be executed, unexpected results are likely if any filenames contain any <blank>s or <newline>s. This can be fixed by using find to call a script that converts each file found into a quoted string that is then piped to xargs. Note that the quoting rules used by xargs are not the same as in the shell. They were not made consistent here because existing applications depend on the current rules and the shell syntax is not fully compatible with it. An easy rule that can be used to transform any string into a quoted form that xargs interprets correctly is to precede each character in the string with a backslash.
On implementations with a large value for $\left\{A R G \_M A X\right\}$, xargs may produce command lines longer than \{LINE_MAX\}. For invocation of utilities, this is not a problem. If xargs is being used to create a text file, users should explicitly set the maximum command line length with the $-\mathbf{s}$ option.
The command, env, nice, nohup, time, and xargs utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish "failure to find a utility" from "invoked utility exited with an error indication". The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for "normal error conditions" and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to exec the utility fail with [ENOENT], and uses 126 when any attempt to exec the utility fails for any other reason.

## EXAMPLES

1. The following command combines the output of the parenthesised commands onto one line, which is then written to the end-of-file log:
```
(logname; date; printf "%s\n" "$0 $*") | xargs >>log
```

2. The following command invokes diff with successive pairs of arguments originally typed as command line arguments (assuming there are no embedded <blank>s in the elements of the original argument list):
printf "\%s\n" "\$*" | xargs -n 2 -x diff
3. In the following commands, the user is asked which files in the current directory are to be archived. The files are archived into arch; $a$, one at a time, or $b$, many at a time.

$$
\text { a. ls } \mid \text { xargs }-\mathrm{p}-\mathrm{L} 1 \text { ar }-\mathrm{r} \text { arch }
$$

b. ls | xargs -p -L 1 | xargs ar $-r$ arch line arguments:

```
echo $* | xargs -n 2 diff
``` \$2, and echoes each move command just before doing it:
```

ls \$1 | xargs -I {} -t mv \$1/{} \$2/{}

```

\section*{RATIONALE} software development extension. This volume of IEEE Std 1003.1-200x does not share the view that it is used only for development, and therefore it is not optional. number of processes launched by a simplistic use of the find -exec combination. The xargs utility is also used to enforce an upper limit on memory required to launch a process. With this basis in mind, this volume of IEEE Std 1003.1-200x selected only the minimal features required. codes are accumulated by xargs. The value could be the addition of all codes, their highest than the others, and since many of the standard utilities say little more (portably) than "pass/fail", no new algorithm was invented.
Several other xargs options were withdrawn because simple alternatives already exist within this volume of IEEE Std 1003.1-200x. For example, the -i replstr option can be just as efficiently option does not usually exploit the grouping capabilities of xargs. within 2048 bytes of hitting the POSIX exec \(\left\{A R G_{-} M A X\right\}\) limitations is intended to guarantee arguments and still be able to invoke another utility. Note that the minimum \{ARG_MAX\} 2048 bytes difference seems reasonable. Note, however, that xargs may never be able to invoke a utility if the environment passed in to xargs comes close to using \{ARG_MAX\} bytes.
The version of xargs required by this volume of IEEE Std 1003.1-200x is required to wait for the completion of the invoked command before invoking another command. This was done because normally. if a -e option was specified. In that case, a simple sed script could be used to duplicate the - \(\mathbf{e}\) functionality. Further investigation revealed that:
4. The following executes with successive pairs of arguments originally typed as command
5. On XSI-conformant systems, the following moves all files from directory \(\mathbf{\$ 1}\) to directory

The xargs utility was usually found only in System V-based systems; BSD systems included an apply utility that provided functionality similar to xargs \(-\mathbf{n}\) number. The SVID lists xargs as a

The classic application of the xargs utility is in conjunction with the find utility to reduce the

Although the 255 exit status is mostly an accident of historical implementations, it allows a utility being used by xargs to tell xargs to terminate if it knows no further invocations using the current data stream shall succeed. Any non-zero exit status from a utility falls into the 1-125 range when xargs exits. There is no statement of how the various non-zero utility exit status value, the last one received, or a single value such as 1 . Since no algorithm is arguably better performed using a shell for loop. Since xargs calls an exec function with each input line, the \(-\mathbf{i}\)

The requirement that xargs never produces command lines such that invocation of utility is that the invoked utility has room to modify its environment variables and command line allowed by the System Interfaces volume of IEEE Std 1003.1-200x is 4096 bytes and the minimum value allowed by this volume of IEEE Std 1003.1-200x is 2048 bytes; therefore, the historical scripts using xargs assumed sequential execution. Implementations wanting to provide parallel operation of the invoked utilities are encouraged to add an option enabling parallel invocation, but should still wait for termination of all of the children before xargs terminates

The -e option was omitted from the ISO POSIX-2: 1993 standard in the belief that the eofstr option-argument was recognized only when it was on a line by itself and before quote and escape processing were performed, and that the logical end-of-file processing was only enabled
- The logical end-of-file string was checked for after quote and escape processing, making a sed script that provided equivalent functionality much more difficult to write.
- The default was to perform logical end-of-file processing with an underscore as the logical end-of-file string.

To correct this misunderstanding, the -E eofstr option was adopted from the X/Open Portability Guide. Users should note that the description of the -E option matches historical documentation of the -e option (which was not adopted because it did not support the Utility Syntax Guidelines), by saying that if eofstr is the null string, logical end-of-file processing is disabled. Historical implementations of xargs actually did not disable logical end-of-file processing; they treated a null argument found in the input as a logical end-of-file string. (A null string argument could be generated using single or double quotes ( \({ }^{\prime}\) or " "). Since this behavior was not documented historically, it is considered to be a bug.
The \(-\mathbf{I}, \mathbf{L}\), and \(\mathbf{- n}\) options are mutually-exclusive. Some implementations use the last one specified if more than one is given on a command line; other implementations treat combinations of the options in different ways.

\section*{FUTURE DIRECTIONS}

None.

Chapter 2 (on page 29), echo, find, the System Interfaces volume of IEEE Std 1003.1-200x, exec

\section*{CHANGE HISTORY}

First released in Issue 2.
Issue 5
A second FUTURE DIRECTION is added.
Issue 6
The obsolescent \(-\mathbf{e},-\mathbf{i}\), and \(-\mathbf{1}\) options are removed.
The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:
- The - \(\mathbf{p}\) option is added.
- In the INPUT FILES section, the file /dev/tty is used to read responses required by the \(-\mathbf{p}\) option.
- The STDERR section is updated to describe the \(-\mathbf{p}\) option.

The description of the-E option is aligned with the ISO POSIX-2: 1993 standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
Issue 7
SD5-XCU-ERN-68 is applied.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
SD5-XCU-ERN-128 is applied, clarifying the DESCRIPTION of the logical end-of-file string.

OPERANDS
The following operand is required:
grammar A pathname of a file containing instructions, hereafter called grammar, for which a parser is to be created. The format for the grammar is described in the EXTENDED DESCRIPTION section.

\section*{STDIN}

Not used.

\section*{INPUT FILES}

The file grammar shall be a text file formatted as specified in the EXTENDED DESCRIPTION section.

\section*{ENVIRONMENT VARIABLES}

The following environment variables shall affect the execution of yacc:
\(L A N G \quad\) Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)

LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.

LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments and input files).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
xsi NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.
The LANG and \(L C_{-}^{*}\) variables affect the execution of the yacc utility as stated. The main() function defined in Yacc Library shall call:
```

setlocale(LC_ALL, "")

```
and thus the program generated by yacc shall also be affected by the contents of these variables at runtime.

\section*{ASYNCHRONOUS EVENTS}

\section*{Default.}

\section*{STDOUT}

Not used.

\section*{STDERR}

If shift/reduce or reduce/reduce conflicts are detected in grammar, yacc shall write a report of those conflicts to the standard error in an unspecified format.

Standard error shall also be used for diagnostic messages.

\section*{OUTPUT FILES}

The code file, the header file, and the description file shall be text files. All are described in the following sections.

\section*{Code File}

This file shall contain the C source code for the yyparse() function. It shall contain code for the various semantic actions with macro substitution performed on them as described in the EXTENDED DESCRIPTION section. It also shall contain a copy of the \#define statements in the header file. If a \%union declaration is used, the declaration for YYSTYPE shall also be included in this file.

\section*{Header File}

The header file shall contain \#define statements that associate the token numbers with the token names. This allows source files other than the code file to access the token codes. If a \%union declaration is used, the declaration for YYSTYPE and an extern YYSTYPE yylval declaration shall also be included in this file.

\section*{Description File}

The description file shall be a text file containing a description of the state machine corresponding to the parser, using an unspecified format. Limits for internal tables (see Limits (on page 1079)) shall also be reported, in an implementation-defined manner. (Some implementations may use dynamic allocation techniques and have no specific limit values to report.)

\section*{EXTENDED DESCRIPTION}

The yacc command accepts a language that is used to define a grammar for a target language to be parsed by the tables and code generated by yacc. The language accepted by yacc as a grammar for the target language is described below using the yacc input language itself.
The input grammar includes rules describing the input structure of the target language and code to be invoked when these rules are recognized to provide the associated semantic action. The code to be executed shall appear as bodies of text that are intended to be C-language code. The C-language inclusions are presumed to form a correct function when processed by yacc into its output files. The code included in this way shall be executed during the recognition of the target language.
Given a grammar, the yacc utility generates the files described in the OUTPUT FILES section. The code file can be compiled and linked using c99. If the declaration and programs sections of the grammar file did not include definitions of main(), yylex(), and yyerror(), the compiled output requires linking with externally supplied versions of those functions. Default versions of \(\operatorname{main}()\) and yyerror() are supplied in the yacc library and can be linked in by using the \(-\mathbf{y}\) operand to c99. The yacc library interfaces need not support interfaces with other than the default yy symbol prefix. The application provides the lexical analyzer function, yylex(); the lex utility is specifically designed to generate such a routine.

\section*{Input Language}

The application shall ensure that every specification file consists of three sections in order: declarations, grammar rules, and programs, separated by double percent signs ("\%\%"). The declarations and programs sections can be empty. If the latter is empty, the preceding \(\% \% \%\) " mark separating it from the rules section can be omitted.
The input is free form text following the structure of the grammar defined below.

\section*{Lexical Structure of the Grammar}

The <blank>s, <newline>s, and <form-feed>s shall be ignored, except that the application shall ensure that they do not appear in names or multi-character reserved symbols. Comments shall be enclosed in " /* . . . */", and can appear wherever a name is valid.

Names are of arbitrary length, made up of letters, periods ( \({ }^{\prime}\) '), underscores ( \({ }^{\prime} \quad\) ' \()\), and noninitial digits. Uppercase and lowercase letters are distinct. Conforming applications shall not use names beginning in yy or YY since the yacc parser uses such names. Many of the names appear in the final output of yacc, and thus they should be chosen to conform with any additional rules created by the C compiler to be used. In particular they appear in \#define statements.

A literal shall consist of a single character enclosed in single-quotes (' ' ' ) . All of the escape sequences supported for character constants by the ISO C standard shall be supported by yacc.
The relationship with the lexical analyzer is discussed in detail below.
The application shall ensure that the NUL character is not used in grammar rules or literals.

\section*{Declarations Section}

The declarations section is used to define the symbols used to define the target language and their relationship with each other. In particular, much of the additional information required to resolve ambiguities in the context-free grammar for the target language is provided here.
Usually yacc assigns the relationship between the symbolic names it generates and their underlying numeric value. The declarations section makes it possible to control the assignment of these values.
It is also possible to keep semantic information associated with the tokens currently on the parse stack in a user-defined C-language union, if the members of the union are associated with the various names in the grammar. The declarations section provides for this as well.
The first group of declarators below all take a list of names as arguments. That list can optionally be preceded by the name of a C union member (called a tag below) appearing within \({ }^{\prime}<\) ' and '>'. (As an exception to the typographical conventions of the rest of this volume of IEEE Std 1003.1-200x, in this case <tag> does not represent a metavariable, but the literal angle bracket characters surrounding a symbol.) The use of tag specifies that the tokens named on this line shall be of the same C type as the union member referenced by tag. This is discussed in more detail below.
For lists used to define tokens, the first appearance of a given token can be followed by a positive integer (as a string of decimal digits). If this is done, the underlying value assigned to it for lexical purposes shall be taken to be that number.
The following declares name to be a token:
```

%token [<tag>] name [number][name [number]]...

```

If tag is present, the \(C\) type for all tokens on this line shall be declared to be the type referenced by tag. If a positive integer, number, follows a name, that value shall be assigned to the token.
The following declares name to be a token, and assigns precedence to it:
\%left [<tag>] name [number][name [number]]...
\%right [<tag>] name [number][name [number]]...
One or more lines, each beginning with one of these symbols, can appear in this section. All tokens on the same line have the same precedence level and associativity; the lines are in order of increasing precedence or binding strength. \%left denotes that the operators on that line are left associative, and \%right similarly denotes right associative operators. If tag is present, it shall
declare a C type for names as described for \%token.
The following declares name to be a token, and indicates that this cannot be used associatively:
```

%nonassoc [<tag>] name [number][name [number]]...

```

If the parser encounters associative use of this token it reports an error. If tag is present, it shall declare a C type for names as described for \%token.

The following declares that union member names are non-terminals, and thus it is required to have a tag field at its beginning:
\%type <tag> name...
Because it deals with non-terminals only, assigning a token number or using a literal is also prohibited. If this construct is present, yacc shall perform type checking; if this construct is not present, the parse stack shall hold only the int type.
Every name used in grammar not defined by a \%token, \%left, \%right, or \%nonassoc declaration is assumed to represent a non-terminal symbol. The yacc utility shall report an error for any nonterminal symbol that does not appear on the left side of at least one grammar rule.
Once the type, precedence, or token number of a name is specified, it shall not be changed. If the first declaration of a token does not assign a token number, yacc shall assign a token number. Once this assignment is made, the token number shall not be changed by explicit assignment.
The following declarators do not follow the previous pattern.
The following declares the non-terminal name to be the start symbol, which represents the largest, most general structure described by the grammar rules:
\%start name
By default, it is the left-hand side of the first grammar rule; this default can be overridden with this declaration.
The following declares the yacc value stack to be a union of the various types of values desired:
```

%union \ body of union (in C) }

```

By default, the values returned by actions (see below) and the lexical analyzer shall be of type int. The yacc utility keeps track of types, and it shall insert corresponding union member names in order to perform strict type checking of the resulting parser.
Alternatively, given that at least one <tag> construct is used, the union can be declared in a header file (which shall be included in the declarations section by using a \#include construct within \(\%\{\) and \(\%\}\) ), and a typedef used to define the symbol YYSTYPE to represent this union. The effect of \%union is to provide the declaration of YYSTYPE directly from the yacc input.
C-language declarations and definitions can appear in the declarations section, enclosed by the following marks:
\(\%\{\). . \% \(\}\)
These statements shall be copied into the code file, and have global scope within it so that they can be used in the rules and program sections.
The application shall ensure that the declarations section is terminated by the token \(\% \%\).

\section*{Grammar Rules in yacc}

The rules section defines the context-free grammar to be accepted by the function yacc generates, and associates with those rules C-language actions and additional precedence information. The grammar is described below, and a formal definition follows.
The rules section is comprised of one or more grammar rules. A grammar rule has the form:
```

A : BODY ;

```

The symbol A represents a non-terminal name, and BODY represents a sequence of zero or more names, literals, and semantic actions that can then be followed by optional precedence rules. Only the names and literals participate in the formation of the grammar; the semantic actions and precedence rules are used in other ways. The colon and the semicolon are yacc punctuation. If there are several successive grammar rules with the same left-hand side, the vertical bar ' \(\left.\right|^{\prime}\) can be used to avoid rewriting the left-hand side; in this case the semicolon appears only after the last rule. The BODY part can be empty (or empty of names and literals) to indicate that the non-terminal symbol matches the empty string.
The yacc utility assigns a unique number to each rule. Rules using the vertical bar notation are distinct rules. The number assigned to the rule appears in the description file.

The elements comprising a BODY are:
name, literal These form the rules of the grammar: name is either a token or a non-terminal; literal stands for itself (less the lexically required quotation marks).
semantic action
With each grammar rule, the user can associate actions to be performed each time the rule is recognized in the input process. (Note that the word "action" can also refer to the actions of the parser-shift, reduce, and so on.)
These actions can return values and can obtain the values returned by previous actions. These values are kept in objects of type YYSTYPE (see \%union). The result value of the action shall be kept on the parse stack with the left-hand side of the rule, to be accessed by other reductions as part of their right-hand side. By using the <tag> information provided in the declarations section, the code generated by yacc can be strictly type checked and contain arbitrary information. In addition, the lexical analyzer can provide the same kinds of values for tokens, if desired.

An action is an arbitrary C statement and as such can do input or output, call subprograms, and alter external variables. An action is one or more C statements enclosed in curly braces \({ }^{\prime}\left\{y^{\prime} \text { and ' }\right\}^{\prime}\).
Certain pseudo-variables can be used in the action. These are macros for access to data structures known internally to yacc.
\$\$ The value of the action can be set by assigning it to \$\$. If type checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.
Snumber This refers to the value returned by the component specified by the token number in the right side of a rule, reading from left to right; number can be zero or negative. If number is zero or negative, it refers to the data associated with the name on the parser's stack preceding the leftmost symbol of the current rule. (That is, "\$0" refers to the name immediately preceding the leftmost name in the current rule to be found on the parser's stack and "\$-1" refers to the symbol to its left.) If number refers to an element past the current point in the rule, or beyond the bottom of the stack, the result is undefined. If type
checking is enabled and the type of the value to be assigned cannot be determined, a diagnostic message may be generated.

\section*{\$<tag>number}

These correspond exactly to the corresponding symbols without the tag inclusion, but allow for strict type checking (and preclude unwanted type conversions). The effect is that the macro is expanded to use tag to select an element from the YYSTYPE union (using dataname.tag). This is particularly useful if number is not positive.
\(\$<t a g>\$ \quad\) This imposes on the reference the type of the union member referenced by tag. This construction is applicable when a reference to a left context value occurs in the grammar, and provides yacc with a means for selecting a type.
Actions can occur anywhere in a rule (not just at the end); an action can access values returned by actions to its left, and in turn the value it returns can be accessed by actions to its right. An action appearing in the middle of a rule shall be equivalent to replacing the action with a new non-terminal symbol and adding an empty rule with that non-terminal symbol on the left-hand side. The semantic action associated with the new rule shall be equivalent to the original action. The use of actions within rules might introduce conflicts that would not otherwise exist.
By default, the value of a rule shall be the value of the first element in it. If the first element does not have a type (particularly in the case of a literal) and type checking is turned on by \%type, an error message shall result.
precedence The keyword \%prec can be used to change the precedence level associated with a particular grammar rule. Examples of this are in cases where a unary and binary operator have the same symbolic representation, but need to be given different precedences, or where the handling of an ambiguous if-else construction is necessary. The reserved symbol \%prec can appear immediately after the body of the grammar rule and can be followed by a token name or a literal. It shall cause the precedence of the grammar rule to become that of the following token name or literal. The action for the rule as a whole can follow \%prec.
If a program section follows, the application shall ensure that the grammar rules are terminated by \%\%.

\section*{Programs Section}

The programs section can include the definition of the lexical analyzer yylex (), and any other functions; for example, those used in the actions specified in the grammar rules. It is unspecified whether the programs section precedes or follows the semantic actions in the output file; therefore, if the application contains any macro definitions and declarations intended to apply to the code in the semantic actions, it shall place them within \(\% \%\{\ldots \%\}\) in the declarations section.

\section*{Input Grammar}

The following input to yacc yields a parser for the input to yacc. This formal syntax takes precedence over the preceding text syntax description.
The lexical structure is defined less precisely; Lexical Structure of the Grammar defines most terms. The correspondence between the previous terms and the tokens below is as follows.

IDENTIFIER This corresponds to the concept of name, given previously. It also includes literals as defined previously.
C_IDENTIFIER This is a name, and additionally it is known to be followed by a colon. A literal cannot yield this token.
NUMBER A string of digits (a non-negative decimal integer).
TYPE, LEFT, MARK, LCURL, RCURL
These correspond directly to \%type, \(\%\) left, \(\% \%, \%\{\), and \(\%\}\).
\{...\} This indicates C-language source code, with the possible inclusion of '\$' macros as discussed previously.

\section*{Conflicts}

The parser produced for an input grammar may contain states in which conflicts occur. The conflicts occur because the grammar is not \(\operatorname{LALR}(1)\). An ambiguous grammar always contains at least one LALR(1) conflict. The yacc utility shall resolve all conflicts, using either default rules or user-specified precedence rules.
Conflicts are either shift/reduce conflicts or reduce/reduce conflicts. A shift/reduce conflict is where, for a given state and lookahead symbol, both a shift action and a reduce action are possible. A reduce/reduce conflict is where, for a given state and lookahead symbol, reductions by two different rules are possible.
The rules below describe how to specify what actions to take when a conflict occurs. Not all shift/reduce conflicts can be successfully resolved this way because the conflict may be due to something other than ambiguity, so incautious use of these facilities can cause the language
accepted by the parser to be much different from that which was intended. The description file shall contain sufficient information to understand the cause of the conflict. Where ambiguity is the reason either the default or explicit rules should be adequate to produce a working parser.
The declared precedences and associativities (see Declarations Section (on page 1071)) are used to resolve parsing conflicts as follows:
1. A precedence and associativity is associated with each grammar rule; it is the precedence and associativity of the last token or literal in the body of the rule. If the \%prec keyword is used, it overrides this default. Some grammar rules might not have both precedence and associativity.
2. If there is a shift/reduce conflict, and both the grammar rule and the input symbol have precedence and associativity associated with them, then the conflict is resolved in favor of the action (shift or reduce) associated with the higher precedence. If the precedences are the same, then the associativity is used; left associative implies reduce, right associative

detected, the parser shall pop back one state at a time until the parse stack is empty or the current state allows a shift over error. If the parser empties the parse stack, it shall return with a non-zero value. Otherwise, it shall shift over error and then resume normal parsing. If the parser reads a lookahead symbol before the error was detected, that symbol shall still be the lookahead symbol when parsing is resumed.

The macro yyerrok in a semantic action shall cause the parser to act as if it has fully recovered from any previous errors. The macro yyclearin shall cause the parser to discard the current lookahead token. If the current lookahead token has not yet been read, yyclearin shall have no effect.

The macro YYACCEPT shall cause the parser to return with the value zero. The macro YYABORT shall cause the parser to return with a non-zero value.

\section*{Interface to the Lexical Analyzer}

The yylex () function is an integer-valued function that returns a token number representing the kind of token read. If there is a value associated with the token returned by yylex () (see the discussion of tag above), it shall be assigned to the external variable yylval.
If the parser and yylex () do not agree on these token numbers, reliable communication between them cannot occur. For (single-byte character) literals, the token is simply the numeric value of the character in the current character set. The numbers for other tokens can either be chosen by yacc, or chosen by the user. In either case, the \#define construct of \(C\) is used to allow yylex () to return these numbers symbolically. The \#define statements are put into the code file, and the header file if that file is requested. The set of characters permitted by yacc in an identifier is larger than that permitted by \(C\). Token names found to contain such characters shall not be included in the \#define declarations.
If the token numbers are chosen by yacc, the tokens other than literals shall be assigned numbers greater than 256 , although no order is implied. A token can be explicitly assigned a number by following its first appearance in the declarations section with a number. Names and literals not defined this way retain their default definition. All token numbers assigned by yacc shall be unique and distinct from the token numbers used for literals and user-assigned tokens. If duplicate token numbers cause conflicts in parser generation, yacc shall report an error; otherwise, it is unspecified whether the token assignment is accepted or an error is reported.
The end of the input is marked by a special token called the endmarker, which has a token number that is zero or negative. (These values are invalid for any other token.) All lexical analyzers shall return zero or negative as a token number upon reaching the end of their input. If the tokens up to, but excluding, the endmarker form a structure that matches the start symbol, the parser shall accept the input. If the endmarker is seen in any other context, it shall be considered an error.

\section*{Completing the Program}

In addition to yyparse() and yylex (), the functions yyerror() and main() are required to make a complete program. The application can supply main() and yyerror(), or those routines can be obtained from the yacc library.

\section*{Yacc Library}

The following functions shall appear only in the yacc library accessible through the \(-\mathbf{1} y\) operand to c99; they can therefore be redefined by a conforming application:

\section*{int main(void)}

This function shall call yyparse() and exit with an unspecified value. Other actions within this function are unspecified.
int yyerror(const char *s)
This function shall write the NUL-terminated argument to standard error, followed by a <newline>.
The order of the \(-\mathbf{1} \mathbf{y}\) and \(-\mathbf{1 1}\) operands given to \(c 99\) is significant; the application shall either provide its own \(\operatorname{main}()\) function or ensure that -1 y precedes -11 .

\section*{Debugging the Parser}

The parser generated by yacc shall have diagnostic facilities in it that can be optionally enabled at either compile time or at runtime (if enabled at compile time). The compilation of the runtime debugging code is under the control of YYDEBUG, a preprocessor symbol. If YYDEBUG has a non-zero value, the debugging code shall be included. If its value is zero, the code shall not be included.
In parsers where the debugging code has been included, the external int yydebug can be used to turn debugging on (with a non-zero value) and off (zero value) at runtime. The initial value of yydebug shall be zero.
When \(\mathbf{- t}\) is specified, the code file shall be built such that, if YYDEBUG is not already defined at compilation time (using the c99-D YYDEBUG option, for example), YYDEBUG shall be set explicitly to 1 . When \(-\mathbf{t}\) is not specified, the code file shall be built such that, if YYDEBUG is not already defined, it shall be set explicitly to zero.
The format of the debugging output is unspecified but includes at least enough information to determine the shift and reduce actions, and the input symbols. It also provides information about error recovery.

\section*{Algorithms}

The parser constructed by yacc implements an LALR(1) parsing algorithm as documented in the literature. It is unspecified whether the parser is table-driven or direct-coded.
A parser generated by yacc shall never request an input symbol from yylex() while in a state where the only actions other than the error action are reductions by a single rule.
The literature of parsing theory defines these concepts.

\section*{Limits}

The yacc utility may have several internal tables. The minimum maximums for these tables are shown in the following table. The exact meaning of these values is implementation-defined. The implementation shall define the relationship between these values and between them and any error messages that the implementation may generate should it run out of space for any internal structure. An implementation may combine groups of these resources into a single pool as long as the total available to the user does not fall below the sum of the sizes specified by this section.

Table 4-22 Internal Limits in yacc
\begin{tabular}{|c|c|c|}
\hline Limit & Minimum Maximum & Description \\
\hline \{NTERMS\} & 126 & Number of tokens. \\
\hline \{NNONTERM\} & 200 & Number of non-terminals. \\
\hline \{NPROD\} & 300 & Number of rules. \\
\hline \{NSTATES\} & 600 & Number of states. \\
\hline \{MEMSIZE\} & 5200 & Length of rules. The total length, in names (tokens and non-terminals), of all the rules of the grammar. The left-hand side is counted for each rule, even if it is not explicitly repeated, as specified in Grammar Rules in yacc (on page 1073). \\
\hline \{ACTSIZE \(\}\) & 4000 & Number of actions. "Actions" here (and in the description file) refer to parser actions (shift, reduce, and so on) not to semantic actions defined in Grammar Rules in yacc (on page 1073). \\
\hline
\end{tabular}

\section*{EXIT STATUS}

The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

If any errors are encountered, the run is aborted and yacc exits with a non-zero status. Partial code files and header files may be produced. The summary information in the description file shall always be produced if the \(-\mathbf{v}\) flag is present.

\section*{APPLICATION USAGE}

Historical implementations experience name conflicts on the names yacc.tmp, yacc.acts, yacc.debug, y.tab.c, y.tab.h, and y.output if more than one copy of yacc is running in a single directory at one time. The -b option was added to overcome this problem. The related problem of allowing multiple yacc parsers to be placed in the same file was addressed by adding a \(-\mathbf{p}\) option to override the previously hard-coded yy variable prefix.
The description of the \(-\mathbf{p}\) option specifies the minimal set of function and variable names that cause conflict when multiple parsers are linked together. YYSTYPE does not need to be changed. Instead, the programmer can use -b to give the header files for different parsers different names, and then the file with the yylex () for a given parser can include the header for that parser. Names such as yyclearerk do not need to be changed because they are used only in the actions; they do not have linkage. It is possible that an implementation has other names, either internal ones for implementing things such as yyclearerr, or providing non-standard features that it wants to change with \(-\mathbf{p}\).

Unary operators that are the same token as a binary operator in general need their precedence adjusted. This is handled by the \%prec advisory symbol associated with the particular grammar rule defining that unary operator. (See Grammar Rules in yacc (on page 1073).) Applications are not required to use this operator for unary operators, but the grammars that do not require it are rare.

\section*{EXAMPLES}

Access to the yacc library is obtained with library search operands to \(c 99\). To use the yacc library main ():
```

c99 y.tab.c -l y

```

Both the lex library and the yacc library contain main( ). To access the yacc main( ):
```

c99 y.tab.c lex.yy.c -l y -l l

```

This ensures that the yacc library is searched first, so that its main() is used.
The historical yacc libraries have contained two simple functions that are normally coded by the application programmer. These functions are similar to the following code:
```

\#include <locale.h>
int main(void)
{
extern int yyparse();
setlocale(LC_ALL, "");
/* If the following parser is one created by lex, the
application must be careful to ensure that LC_CTYPE
and LC_COLLATE are set to the POSIX locale. */
(void) yyparse();
return (0);
}
\#include <stdio.h>
int yyerror(const char *msg)
{
(void) fprintf(stderr, "%s\n", msg);
return (0);
}

```

\section*{RATIONALE}

The references in Referenced Documents may be helpful in constructing the parser generator. The referenced DeRemer and Pennello article (along with the works it references) describes a technique to generate parsers that conform to this volume of IEEE Std 1003.1-200x. Work in this area continues to be done, so implementors should consult current literature before doing any new implementations. The original Knuth article is the theoretical basis for this kind of parser, but the tables it generates are impractically large for reasonable grammars and should not be used. The "equivalent to" wording is intentional to assure that the best tables that are \(\operatorname{LALR}(1)\) can be generated.
There has been confusion between the class of grammars, the algorithms needed to generate parsers, and the algorithms needed to parse the languages. They are all reasonably orthogonal. In particular, a parser generator that accepts the full range of \(\operatorname{LR}(1)\) grammars need not generate a table any more complex than one that accepts SLR(1) (a relatively weak class of LR grammars) for a grammar that happens to be SLR(1). Such an implementation need not recognize the case, either; table compression can yield the \(\operatorname{SLR}(1)\) table (or one even smaller than that) without recognizing that the grammar is \(\operatorname{SLR}(1)\). The speed of an \(\operatorname{LR}(1)\) parser for any class is dependent more upon the table representation and compression (or the code generation if a direct parser is generated) than upon the class of grammar that the table generator handles.
The speed of the parser generator is somewhat dependent upon the class of grammar it handles. However, the original Knuth article algorithms for constructing LR parsers were judged by its author to be impractically slow at that time. Although full LR is more complex than \(\operatorname{LALR}(1)\), as computer speeds and algorithms improve, the difference (in terms of acceptable wall-clock
execution time) is becoming less significant.
Potential authors are cautioned that the referenced DeRemer and Pennello article previously cited identifies a bug (an over-simplification of the computation of LALR(1) lookahead sets) in some of the LALR(1) algorithm statements that preceded it to publication. They should take the time to seek out that paper, as well as current relevant work, particularly Aho's.

The -b option was added to provide a portable method for permitting yacc to work on multiple separate parsers in the same directory. If a directory contains more than one yacc grammar, and both grammars are constructed at the same time (by, for example, a parallel make program), conflict results. While the solution is not historical practice, it corrects a known deficiency in historical implementations. Corresponding changes were made to all sections that referenced the filenames y.tab.c (now "the code file"), y.tab.h (now "the header file"), and y.output (now "the description file").
The grammar for yacc input is based on System V documentation. The textual description shows there that the \({ }^{\prime} ;^{\prime}\) is required at the end of the rule. The grammar and the implementation do not require this. (The use of C_IDENTIFIER causes a reduce to occur in the right place.)
Also, in that implementation, the constructs such as \%token can be terminated by a semicolon, but this is not permitted by the grammar. The keywords such as \%token can also appear in uppercase, which is again not discussed. In most places where \({ }^{\prime \%} \prime^{\prime}\) is used, \(\backslash{ }^{\prime}\) can be substituted, and there are alternate spellings for some of the symbols (for example, \%LEFT can be "\%<" or even " \(\backslash<\) ").

Historically, <tag> can contain any characters except '>', including white space, in the implementation. However, since the tag must reference an ISO C standard union member, in practice conforming implementations need to support only the set of characters for ISO C standard identifiers in this context.
Some historical implementations are known to accept actions that are terminated by a period. Historical implementations often allow ' \(\$^{\prime}\) in names. A conforming implementation does not need to support either of these behaviors.

Deciding when to use \%prec illustrates the difficulty in specifying the behavior of yacc. There may be situations in which the grammar is not, strictly speaking, in error, and yet yacc cannot interpret it unambiguously. The resolution of ambiguities in the grammar can in many instances be resolved by providing additional information, such as using \%type or \%union declarations. It is often easier and it usually yields a smaller parser to take this alternative when it is appropriate.
The size and execution time of a program produced without the runtime debugging code is usually smaller and slightly faster in historical implementations.
Statistics messages from several historical implementations include the following types of information:
n/512 terminals, \(n / 300\) non-terminals
\(n / 600\) grammar rules, \(n / 1500\) states
\(n\) shift/reduce, \(n\) reduce/reduce conflicts reported
\(n / 350\) working sets used
Memory: states, etc. n/15000, parser \(n / 15000\)
\(n / 600\) distinct lookahead sets
\(n\) extra closures
\(n\) shift entries, \(n\) exceptions
\(n\) goto entries
\(n\) entries saved by goto default
Optimizer space used: input \(n / 15000\), output \(n / 15000\)
\(n\) table entries, \(n\) zero

Maximum spread: n, Maximum offset: n
The report of internal tables in the description file is left implementation-defined because all aspects of these limits are also implementation-defined. Some implementations may use dynamic allocation techniques and have no specific limit values to report.
The format of the y.output file is not given because specification of the format was not seen to enhance applications portability. The listing is primarily intended to help human users understand and debug the parser; use of y.output by a conforming application script would be unusual. Furthermore, implementations have not produced consistent output and no popular format was apparent. The format selected by the implementation should be human-readable, in addition to the requirement that it be a text file.

Standard error reports are not specifically described because they are seldom of use to conforming applications and there was no reason to restrict implementations.
Some implementations recognize " \(=\left\{\right.\) " as equivalent to \({ }^{\prime}\) \{' because it appears in historical documentation. This construction was recognized and documented as obsolete as long ago as 1978, in the referenced Yacc: Yet Another Compiler-Compiler. This volume of IEEE Std 1003.1-200x chose to leave it as obsolete and omit it.

Multi-byte characters should be recognized by the lexical analyzer and returned as tokens. They should not be returned as multi-byte character literals. The token error that is used for error recovery is normally assigned the value 256 in the historical implementation. Thus, the token value 256, which is used in many multi-byte character sets, is not available for use as the value of a user-defined token.

\section*{FUTURE DIRECTIONS}

None.
SEE ALSO
c99, lex

\section*{CHANGE HISTORY}

First released in Issue 2.

\section*{Issue 5}

The FUTURE DIRECTIONS section is added.
Issue 6
This utility is marked as part of the C-Language Development Utilities option.
Minor changes have been added to align with the IEEE P1003.2b draft standard.
The normative text is reworded to avoid use of the term "must" for application requirements.
IEEE PASC Interpretation 1003.2 \#177 is applied, changing the comment on RCURL from the \(\} \%\) token to the \(\%\) \}.

Issue 7
SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not apply.
SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.
```

NAME
zcat - expand and concatenate data
SYNOPSIS
XSI zcat [file...]

```

\section*{DESCRIPTION}
```

The zcat utility shall write to standard output the uncompressed form of files that have been compressed using the compress utility. It is the equivalent of uncompress -c. Input files are not affected.

```

\section*{OPTIONS}
```

None.
OPERANDS
The following operand shall be supported:
file The pathname of a file previously processed by the compress utility. If file already has the. $\mathbf{Z}$ suffix specified, it is used as submitted. Otherwise, the $\mathbf{Z}$ suffix is appended to the filename prior to processing.

```

\section*{STDIN}
```

The standard input shall be used only if no file operands are specified, or if a file operand is ' ${ }^{\prime}$.

```

\section*{INPUT FILES}
```

Input files shall be compressed files that are in the format produced by the compress utility.

```

\section*{ENVIRONMENT VARIABLES}
```

The following environment variables shall affect the execution of zcat:
LANG Provide a default value for the internationalization variables that are unset or null. (See the Base Definitions volume of IEEE Std 1003.1-200x, Section 8.2, Internationalization Variables for the precedence of internationalization variables used to determine the values of locale categories.)
LC_ALL If set to a non-empty string value, override the values of all the other internationalization variables.
LC_CTYPE Determine the locale for the interpretation of sequences of bytes of text data as characters (for example, single-byte as opposed to multi-byte characters in arguments).
LC_MESSAGES
Determine the locale that should be used to affect the format and contents of diagnostic messages written to standard error.
NLSPATH Determine the location of message catalogs for the processing of LC_MESSAGES.

```

\section*{ASYNCHRONOUS EVENTS}
```

Default.

```

\section*{STDOUT}
```

The compressed files given as input shall be written on standard output in their uncompressed form.

```

\section*{STDERR}

The standard error shall be used only for diagnostic messages.

\section*{OUTPUT FILES}

None.
EXTENDED DESCRIPTION
None.
EXIT STATUS
The following exit values shall be returned:
0 Successful completion.
\(>0\) An error occurred.

\section*{CONSEQUENCES OF ERRORS}

Default.
APPLICATION USAGE
None.
EXAMPLES
None.
RATIONALE
None.

\section*{FUTURE DIRECTIONS}

```

[^0]:    1. The Austin Group is named after the location of the inaugural meeting held at the IBM facility in Austin, Texas in September 1998.
    2. The name POSIX was suggested by Richard Stallman. It is expected to be pronounced pahz-icks, as in positive, not poh-six, or other variations. The pronunciation has been published in an attempt to promulgate a standardized way of referring to a standard operating system interface.
